- Speak with the patient (except for VAP patients) or family members to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Evaluate the symptoms, and status (ie, inpatient, outpatient, or intubated) to determine the type of pneumonia.
- Identify comorbid conditions of asthma, COPD, or emphysema, smoking history to determine if there are factors that could slow or alter the rate of response to therapy due to bronchial or lung damage or impact the pathogen list.
- Review chest X-ray, pulse oximetry, laboratory values, microbiology data, and vital signs available.
- Assess allergies and drug intolerances, noting the severity of the reaction.
- Identify any significant drug interactions or adverse drug effects.

Develop a Care Plan:

- Determine the top two to three organisms associated with the type of pneumonia for the patient (Table 74–1).
- Select an appropriate empirical antibiotic regimen for the patient and type of pneumonia, ensuring that the doses are correct for renal function and medication allergies or intolerances (see **Tables 74–2** and **74–3**).

Implement the Care Plan:

- Educate the patient on the importance of completing their antibiotic therapy, medication adverse effects, and drug interactions.
- Address any patient concerns regarding their pneumonia and its management.
- Determine whether the patient has insurance coverage or if the recommended agent(s) are included on the institution's formulary.

Follow-up: Monitor and Evaluate:

- Assess the effectiveness of the antibiotic therapy after 24 to 72 hours looking for improvement in signs and symptoms.
- If the patient responds to therapy within the first 72 hours, consider a 5- to 7-day course of therapy for CAP and HAP/VAP, respectively. If inpatient status, assess the patient for conversion from IV to oral therapy.
- If the patient is not improving, then reevaluate the diagnosis and pathogen list, and make appropriate changes to therapy.
- Assess the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.
- Discuss with the patient the value of vaccination against *S. pneumoniae* and/or influenza. Recommend and administer vaccinations annually during the season for influenza and as appropriate for the patient for *S. pneumoniae*.

Abbreviations Introduced in This Chapter

ARDS	Acute respiratory distress syndrome
ATS	American Thoracic Society
BUN	Blood urea nitrogen
CA-MRSA	Community-acquired methicillin-resistant *Staphylococcus aureus*
CAP	Community-acquired pneumonia
CDC	Centers for Disease Control and Prevention
COPD	Chronic obstructive pulmonary disease
DFA	Direct fluorescence antigen
GER(D)	Gastroesophageal reflux (disease)
H	Hemagglutinin
HAP	Hospital-acquired pneumonia
IDSA	Infectious Diseases Society of America
MDR	Multidrug resistant
MRSA	Methicillin-resistant *Staphylococcus aureus*
MSSA	Methicillin-susceptible *Staphylococcus aureus*
N	Neuraminidase
PBP	Penicillin-binding protein
PCR	Polymerase chain reaction
PCV13	Pneumococcal 13-valent conjugated vaccine
PPSV23	Purified-capsular polysaccharide 23-antigen vaccine
TNF-α	Tumor necrosis factor alpha
VAP	Ventilator-associated pneumonia

75 Upper Respiratory Tract Infections

Heather L. Girand

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. List common bacteria that cause acute otitis media (AOM), acute bacterial rhinosinusitis (ABRS), and acute pharyngitis.
2. Explain the pathophysiology of and risk factors for AOM, ABRS, and streptococcal pharyngitis.
3. Identify clinical signs and symptoms associated with AOM, ABRS, streptococcal pharyngitis, and the common cold.
4. List treatment goals for AOM, ABRS, streptococcal pharyngitis, and the common cold.
5. Develop a treatment plan for a patient with an upper respiratory tract infection (URI) based on patient-specific information.
6. Create a monitoring plan for a patient with a URI based on patient-specific information and the treatment regimen.
7. Formulate appropriate educational information for patients about URIs and proper antibiotic use.

INTRODUCTION

Upper respiratory tract infection (URI) is a comprehensive term for upper airway infections, including otitis media, sinusitis, pharyngitis, laryngitis, and the common cold. Over 1 billion URIs occur annually in the United States, triggering millions of antibiotic prescriptions each year, of which up to 50% are considered inappropriate for use for acute respiratory conditions.[1] **KEY CONCEPT** Most URIs are caused by viruses, have nonspecific symptoms, and resolve spontaneously.[2] Antibiotics are not effective for viral URIs, and their excessive use has contributed to resistance, which has prompted development of clinical guidelines and national campaigns to reduce inappropriate prescribing.[2-7] This chapter focuses on acute otitis media (AOM), sinusitis, and pharyngitis, which are frequently caused by viruses but may be caused by bacteria. Proper management of the common cold is also reviewed.

OTITIS MEDIA

Otitis media, or middle ear inflammation, is the most common childhood illness treated with antibiotics. It can be subclassified as otitis media with effusion (OME) or AOM. OME is characterized by the presence of a noninfectious effusion, or fluid, in the middle ear and is not an acute illness. AOM is a rapid, symptomatic infection with middle ear effusion that usually results from an initial nasopharyngeal viral infection. Antibiotics are only useful for the treatment of some AOM episodes. While the use of antibiotics for otitis media has declined since the mid-1990s, antibiotic prescription rates remain as high as 60% to 80%.[1,8]

Epidemiology and Etiology

AOM occurs in all ages but has a peak incidence in the first year of life. By 3 years of age, about 60% of children have had at least one episode of AOM and nearly 25% have had at least three episodes of AOM.[9] Many risk factors (Table 75–1) predispose children to otitis media.[9,10]

Although AOM occurs frequently with viral URIs, bacteria are isolated from middle ear fluid in 70% to 90% of children with AOM.[3,9] Historically, *Streptococcus pneumoniae* was the most common organism, responsible for up to half of bacterial cases.[3,9] *Haemophilus influenzae* and *Moraxella catarrhalis* caused up to 30% and 20% of cases, respectively. Routine childhood pneumococcal vaccination has altered the microbiology such that *H. influenzae* is now responsible for up to 60% of bacterial cases.[9,11] Viruses are isolated from middle ear fluid with or without concomitant bacteria in up to 70% of cases.[12] Lack of improvement with antibiotics is usually a result of viral infection and subsequent inflammation rather than antibiotic resistance.

Antibiotics should have adequate activity against *S. pneumoniae* because pneumococcal AOM is unlikely to resolve spontaneously and commonly results in more ear pain and fever.[3,11] Penicillin-resistant *S. pneumoniae* (PRSP) exhibit intermediate resistance (minimum inhibitory concentrations [MIC] between 0.12 and 1.0 mcg/mL [0.12 and 1.0 mg/L]) or high-level resistance (MIC of 2.0 mcg/mL [2.0 mg/L] and higher). Altered penicillin-binding proteins cause resistance in 30% to 35% of pneumococci with up to half of these strains exhibiting high-level resistance.[9,13,14] Recent data show that the prevalence of high-level penicillin resistance is less than 5% in pneumococci obtained from children.[15] Amoxicillin resistance is less common than penicillin resistance, occurring in 2% to 4% of pneumococci.[14,15] PRSP are frequently resistant to other drug classes, including sulfonamides, macrolides, and clindamycin but are usually susceptible to levofloxacin.[14] β-Lactamase production occurs in 20% to 45% of *H. influenzae* and 90% to 100% of *M. catarrhalis* strains.[9,11] Although infections caused by these organisms are more likely to

Table 75–1

Risk Factors for Otitis Media[9,10]

- Adenoid hypertrophy
- Atopy
- Craniofacial defects
- Daycare attendance
- Gastroesophageal reflux
- Immunodeficiency
- Lack of breast-feeding
- Low socioeconomic status
- Male sex
- Non-Hispanic White race
- Pacifier use
- Positive family history/genetic predisposition
- Siblings
- Tobacco smoke exposure
- Upper respiratory tract infection
- Winter season
- Young age

resolve without treatment, they should be considered when failure occurs or when there is recurrent disease.[3,11]

Pathophysiology

AOM is caused by an interplay of factors. Viral URIs impair eustachian tube function and cause mucosal inflammation, impairing mucociliary clearance and promoting bacterial proliferation and infection. Children are predisposed because they have shorter, more flaccid, and more horizontal eustachian tubes than adults, which are less functional for middle ear drainage and protection. Clinical manifestations of AOM result from host immune response and cellular damage from inflammatory mediators released by bacteria.

Viscous effusions caused by allergy or irritant exposure contribute to impaired mucociliary clearance and AOM in susceptible individuals. Effusions can persist for up to 6 months after an episode of AOM. Atopic children experience chronic OME that may require **tympanostomy tube** placement to reduce complications such as hearing and speech impairment and recurrent AOM.

Patient Encounter 1, Part 1

A 9-month-old Caucasian boy presents to the family medicine clinic with 18 hours of fever (maximum temperature of 38.7°C [101.7°F]) and 3 days of rhinorrhea and nasal congestion. His mother states that her son is irritable and was crying intermittently last night with interrupted sleep. He has not eaten well this morning. Both of the child's parents have had upper respiratory tract infection symptoms with rhinorrhea and nasal congestion over the past week. The child attends daycare 3 days a week.

What information is suggestive of acute otitis media (AOM)?

What risk factors does this child have for AOM?

Is there any additional information you need to know before recommending a treatment plan?

Treatment

The goals of treatment are to alleviate ear pain and fever; eradicate infection; prevent complications; and avoid unnecessary antibiotic use.

▶ *General Approach to Treatment*

Most uncomplicated cases of AOM do not require antibiotic treatment and will resolve spontaneously. Untreated AOM improves in over 80% of children between days 2 and 3 of illness without increasing complications.[16] Antibiotics improve **otalgia** in only 5% of children between days 2 and 3 of therapy while *increasing* the risk of adverse effects by 38%.[16] Antibiotics significantly improve recovery in children younger than 2 years with bilateral AOM and in those with AOM and otorrhea.[16] Children

Clinical Presentation and Diagnosis of AOM

Patients with AOM usually have URI symptoms, including rhinorrhea, cough, or nasal congestion, before or at diagnosis.

Symptoms

- Young children: ear tugging or rubbing, irritable, poor sleeping and eating
- Older patients: ear pain, ear fullness, hearing impairment

Signs[3]

- Fever: not common in older children; often in younger children
- Middle ear effusion
- Otorrhea with tympanic membrane perforation
- Bulging tympanic membrane
- Limited or absent mobility of tympanic membrane
- Distinct erythema of tympanic membrane
- Opaque tympanic membrane that obscures middle ear visibility

Laboratory Tests

- Gram stain, culture, and sensitivities of ear fluid if draining spontaneously or obtained via **tympanocentesis** (not performed routinely in practice)

Complications

- Infectious (rare; occur in < 1%): mastoiditis, meningitis, osteomyelitis, intracranial abscess
- Structural: perforated eardrum (occurs in up to 20%), **cholesteatoma** (rare; occurs in < 1%)
- Hearing and/or speech impairment (transient impairment occurs in most patients)

Diagnosis[3]

AOM should be diagnosed if any of the following are present:

- Moderate-to-severe bulging of tympanic membrane (usually with impaired mobility as assessed by **pneumatic otoscopy**)
- Mild bulging of tympanic membrane *and* recent onset (< 48 hours) of otalgia (or ear rubbing/tugging in nonverbal child) or intense erythema of tympanic membrane
- New onset otorrhea not caused by acute otitis externa
- Severe AOM: Moderate-to-severe otalgia or otalgia for at least 48 hours *or* temperature of 39.0°C (102.2°F) or greater

younger than 2 years have a higher incidence of PRSP infections, and children between 6 months and 3 years have higher clinical and bacteriologic failure rates and complications without initial antibiotic treatment as compared with older children.[3,17] Patients with severe AOM have lower spontaneous recovery rates than those with less severe disease, particularly in children less than 2 years.[3,18] **KEY CONCEPT** Therefore, antibiotics should be reserved for patients most likely to benefit, which is dependent on proper diagnosis, patient age, and illness severity. Current guidelines stratify patients using these criteria in order to identify those most likely to benefit from antibiotics.[3]

▶ *Nonpharmacologic Therapy*

Watchful waiting and delayed antibiotic prescriptions (prescription given to the patient but only filled if symptoms persist or worsen within 48–72 hours after diagnosis) are approaches used to attenuate microbial resistance and avoid unnecessary antibiotic adverse effects and costs. Initial observation and use of delayed prescriptions in older children and those with less severe disease can reduce antibiotic use by 60% without increasing complications.[16,19] These approaches should only be considered in otherwise healthy children (Figure 75–1) as a joint decision between the clinician and the parent/caregiver and only if close follow-up and good communication exist.[3]

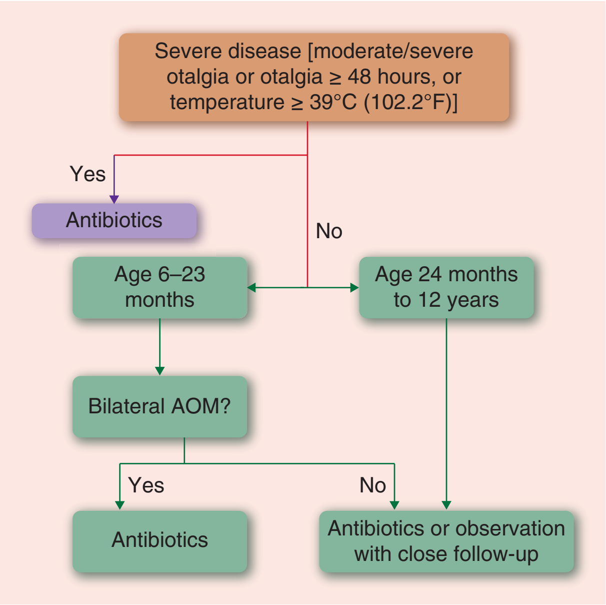
Children with recurrent AOM or chronic OME with impaired hearing or speech may benefit from surgery (tympanostomy tube placement with or without adenoidectomy).

▶ *Pharmacologic Therapy*

Adjunctive Therapy Pain is a central feature of AOM but it is often overlooked. Analgesics provide relief within 24 hours and should be used regardless of antibiotic therapy.[3] Acetaminophen and ibuprofen are commonly used for mild-to-moderate pain. Ibuprofen provides longer relief than acetaminophen but should be avoided in children younger than 6 months because of increased toxicity concerns. Alternating ibuprofen with acetaminophen is not recommended because of the potential for dosing error in ambulatory settings and a lack of safety and efficacy data. Aspirin should be avoided in children because of the risk for Reye syndrome. Myringotomy provides immediate relief but is rarely performed. Decongestants, antihistamines, and corticosteroids have no role in AOM treatment and can prolong effusion duration.[3,20] Data are lacking on the safety and efficacy of complementary and alternative treatments.

Antibiotic Therapy When antibiotics are necessary, clinicians must consider drug factors (eg, antimicrobial spectrum, likelihood of response, middle ear fluid penetration, side effects, drug interactions, and cost) and patient factors (eg, risk factors for resistance, allergies, regimen complexity, medication palatability, and the presence of other medical conditions). Studies in uncomplicated AOM have not revealed significant differences between antibiotics in clinical response rates, but most were confounded by spontaneous resolution in children likely to have had viral URIs. Bacteriologic response varies among antibiotics and does not always correlate well with clinical response but is considered important when selecting therapy.[3]

The American Academy of Pediatrics (AAP) developed clinical guidelines for healthy children between 6 months and 12 years of age with uncomplicated AOM (Figure 75–2).[3] **KEY CONCEPT** Amoxicillin is the drug of choice in most patients because of its proven effectiveness, high middle ear concentrations, excellent safety profile, low cost, palatable suspension, and relatively narrow spectrum (Table 75–2). High-dose amoxicillin (80–90 mg/kg/day) is preferred over conventional doses (40–45 mg/kg/day) because higher middle ear fluid concentrations can overcome pneumococcal penicillin resistance without substantially increasing adverse effects.[3,21] High-dose amoxicillin–clavulanate is preferred for children who received amoxicillin in the previous 30 days, have concurrent purulent conjunctivitis,



Severe disease [moderate/severe otalgia or otalgia ≥ 48 hours, or temperature ≥ 39°C (102.2°F)]

Table 75–2

Antibiotics[a] for the Treatment of Acute Otitis Media

Drug	Usual Dose and Schedule	Common Adverse Effects	Relative Cost[b]	Comments
Amoxicillin	80–90 mg/kg/day divided in two doses (adult: 875 mg twice daily)	Nausea, vomiting, diarrhea, rash	$	Drug of choice for AOM; experts recommend high dose to overcome penicillin resistance
Amoxicillin–clavulanate	90 mg/kg/day divided in two doses (adult: 875 mg twice daily)	Nausea, vomiting, diarrhea, rash, diaper rash	$$	More diarrhea than amoxicillin; amoxicillin:clavulanate ratio of 14:1 preferred because of lower daily clavulanate component
Cefdinir	14 mg/kg/day divided in one to two doses (adult: 300 mg twice daily or 600 mg once daily)	Diarrhea, rash, vomiting, diaper rash, yeast infections	$$	Preferred oral cephalosporin (pleasant taste); separate from Fe supplements by 3 hours
Cefpodoxime proxetil	10 mg/kg/day divided in two doses (adult: 200 mg twice daily)	Diarrhea, diaper rash, vomiting, rash, yeast infections	$$$–$$$$	Suspension is bitter tasting
Ceftriaxone	50 mg/kg IM or IV for 1 or 3 days (max 1 g/dose)	Injection site pain, swelling, or erythema; diarrhea, rash	$$$–$$$$	3-day regimen preferred for PRSP
Cefuroxime axetil	30 mg/kg/day divided in two doses (adult: 250 mg twice daily)	Nausea, vomiting, diarrhea, rash, diaper rash	$$–$$$	Suspension is no longer available in the United States

[a] Other FDA-approved antibiotics for AOM not recommended in AAP guidelines: azithromycin, cefaclor, cefixime, cefprozil, ceftibuten, cephalexin, clarithromycin, erythromycin-sulfisoxazole, and trimethoprim–sulfamethoxazole.

[b] Approximate cost per course: $ (under $25), $$ ($25–$50), $$$ ($50–$100), $$$$ (over $100).

AAP, American Academy of Pediatrics AOM, acute otitis media; Fe, iron; IM, intramuscular; IV, intravenous; PRSP, penicillin-resistant *S. pneumoniae.*

Data from Lieberthal AS, Carroll AE, Chonmaitree T, et al. The diagnosis and management of acute otitis media. Pediatrics. 2013;131(3):e964–e999.

have a history of recurrent AOM unresponsive to amoxicillin, and when coverage for β-lactamase–producing organisms is desired.[3] Despite reported high rates of penicillin allergies, only those with immunologic penicillin or amoxicillin allergies, such as hives, require alternative therapy (see Figure 75–2). There is limited cross-reactivity between penicillins and newer cephalosporins, which supports AAP recommendations to use cephalosporins in penicillin-allergic patients because they are more effective than alternatives.[3,22] Trimethoprim–sulfamethoxazole and macrolides are less active against *S. pneumoniae* and *H. influenzae* than the preferred cephalosporins, making them less appropriate for most penicillin-allergic patients.[3,14,23] Single-dose intramuscular ceftriaxone is effective for children who cannot tolerate oral medications, but a 3-day course may be preferred to prevent recurrence caused by resistant pneumococci and because of reported treatment failures with single doses.[3] Ototopical antibiotic and glucocorticoid combinations are more effective than systemic antibiotics for patients with acute otorrhea and tympanostomy tubes.[24]

If there is no improvement or worsening with initial therapy during the first 48 to 72 hours, proper diagnosis and antibiotic selection must be reassessed.[3] Tympanocentesis can assist with guiding therapy in difficult cases.

Duration of antimicrobial therapy depends on antibiotic selection, patient characteristics, and acceptability of failure if a short treatment course is used. The risk of treatment failure within 1 month is modestly higher with short-course therapy (3–5 day regimens) than standard-course therapy (minimum 7 days), but failure rates with short-course therapy are significantly higher in children with perforated eardrums.[25] Failure with short-course amoxicillin–clavulanate is also significantly more common in children 6 to 23 months of age as compared to 10 days of therapy.[26] Short-course regimens have not been proven to reduce the rates of adverse events or emergence of microbial resistance.[25,26] Standard 10-day regimens are recommended for all severe infections and for children younger than 2 years.[3] 7-day regimens and 5- to 7-day regimens can be considered for mild-to-moderate AOM in children 2 to 5 years and children 6 years and older, respectively.[3]

Prevention

Influenza vaccines and pneumococcal conjugate vaccines may prevent AOM in certain patients, but their benefits are small, and they should not be administered solely for this purpose.[27,28] Antibiotic prophylaxis is not recommended because of selection pressure on microbial resistance. Exclusive breast-feeding for the first 6 months of life, avoiding supine feeding, and reducing or eliminating pacifier use in the second 6 months of life have been associated with a reduced incidence and recurrence of AOM.[3] Avoidance of tobacco smoke and treatment of gastroesophageal reflux (if present) are advised, but the effects of these interventions on AOM remain unproven.

Outcome Evaluation

Improvement of signs and symptoms (ie, pain, fever, and tympanic membrane inflammation) should be evident by 72 hours of proper therapy. Children can appear clinically worse during the first 24 hours but often stabilize during the second day. If symptoms persist or worsen, reevaluate the patient for the proper diagnosis and treatment. Counsel patients and caregivers regarding common antibiotic adverse effects such as rash, diarrhea, and vomiting that may prompt additional medical attention.

Patient Care Process for Upper Respiratory Tract Infections

Collect Information:

- Perform a medication history including prescription and nonprescription medications or therapies and dietary supplements. Identify allergies and adverse reactions to medications or other substances and document reaction(s) that occurred. Gather information on immunization history from the patient or patient's parent or caregiver and medical records including immunization registry, if applicable.
- Review the medical history and physical examination findings.
- Speak with the patient or patient's parent or caregiver to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Based on patient history and physical examination findings, determine if the patient has a bacterial infection and, if present, whether it is severe and/or recurrent.
- Determine if antibiotic therapy is indicated.
- Determine if the patient is current or behind on recommended immunizations.
- Determine if modifiable risk factors are present, such as exposure to tobacco smoke.
- Assess the effectiveness, safety, and patient adherence of current pharmacotherapy, where applicable.
- Identify comorbidities or conditions that may complicate the treatment plan or prompt referral to a specialist.

Develop a Care Plan:

- Select appropriate analgesic therapy that will provide optimal pain relief and appropriate adjunctive therapies to relieve symptoms.
- If appropriate, select antibiotic therapy that is likely to be effective and safe.
- Select an optimal antibiotic dose and an appropriate duration of treatment based on patient age and illness severity.

Implement the Care Plan:

- Discuss expectations for improvement of signs and symptoms with the patient, parent, or caregiver.
- Discuss importance of medication adherence to treat symptoms and infection.
- Discuss potential medication adverse effects and how to manage them.
- When appropriate, recommend and/or administer influenza and pneumococcal conjugate vaccinations to reduce risk for future infections.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist or worsen.

The presence of middle ear effusion in the absence of symptoms is not an indicator of treatment failure. Evaluate hearing in children who are otherwise healthy and have persistent effusion lasting 3 months in duration. Preschool-aged and younger children or those at risk for developmental difficulties may need reexamination earlier because speech and hearing impairment is more difficult to assess in these populations.

SINUSITIS

Sinusitis, or paranasal sinus inflammation, occurs in nearly all viral URIs and is often described as rhinosinusitis because it involves contiguous nasal mucosa. Acute rhinosinusitis is characterized by symptoms that persist for up to 4 weeks, whereas chronic rhinosinusitis lasts for more than 12 weeks. Acute bacterial rhinosinusitis (ABRS) refers to an acute bacterial sinus infection that occurs independently of or is superimposed on chronic sinusitis. This section will focus on ABRS.

Epidemiology and Etiology

Rhinosinusitis affects 12% of adults annually in the United States.[4] It is caused mainly by respiratory viruses but can also be triggered by allergies or environmental irritants. Viral rhinosinusitis is complicated by secondary bacterial infection in 0.2% to 2% of adults and 5% to 7% of children.[5,6] Sinusitis is the most common diagnosis associated with antibiotic prescriptions; they are used in 70% to 85% of cases, of which up to half are considered inappropriate.[1] URIs of less than 7 to 10 days' duration are usually viral, whereas more prolonged or severe symptoms are often caused by bacteria. Common risk factors for ABRS include

Patient Encounter 1, Part 2

On further questioning, his mother states that he is allergic to cephalexin. He was treated for impetigo 2 months ago and experienced diarrhea while taking this antibiotic. He has not received antibiotics since that time, and this is his first ear infection.

Immunizations: Up to date but has not received any influenza vaccines

Meds: Acetaminophen 120 mg orally every 4 to 6 hours as needed for fever

ROS: (+) rhinorrhea, nasal congestion, and fever, (–) vomiting, diarrhea, or cough

PE:

Gen: Irritable child but consolable

VS: BP 86/58 mm Hg, P 140 beats/min, RR 28 breaths/min, T 38.6°C (101.5°F), Weight 10 kg

HEENT: Moderate bulging of the left tympanic membrane with air–fluid levels observed; marked erythema and moderate bulging of the right tympanic membrane

Identify your treatment goals for this child.

Given this information, what nonpharmacologic and pharmacologic therapy do you recommend?

Patient Care Process for Acute Otitis Media

See Patient Care Process for Upper Respiratory Tract Infections.

Assess the Information:

- Determine if antibiotic therapy is indicated or if observation can be employed (see Figure 75–1).

Develop a Care Plan:

- If appropriate, select an antibiotic (see Figure 75–2) and optimal dose and duration (see Table 75–2).

Implement the Care Plan:

- Educate parents or caregivers that pain, fever, and/or other symptoms should improve but may not resolve completely within 48 to 72 hours and can be present for up to 7 days or longer in some patients.
- After joint decision with parent or caregiver, refer children with recurrent AOM (three distinct episodes within 6 months or four episodes within 12 months with at least one episode in preceding 6 months) and/or chronic OME to an otolaryngologist for surgical evaluation and treatment.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist after 48 to 72 hours of initial evaluation and treatment or worsen at any time.
- Monitor for middle ear effusion resolution at an appropriate interval based on age and the presence of conditions that interfere with recognition of hearing impairment.
- Evaluate hearing if middle ear effusion is present for 3 months in healthy children and earlier in children who are at risk for speech, language, or learning problems.

viral URI, allergic rhinitis, and dental infections or procedures (Table 75–3).[6,29,30]

Bacteria that cause sinusitis are similar to those in AOM. *S. pneumoniae* and *H. influenzae* cause more than half of ABRS cases, with an additional 8% to 16% of cases caused by *M. catarrhalis*.[4-6] Similar to AOM, an increased prevalence of *H. influenzae* has been reported in ABRS, and certain factors predict the presence of drug-resistant pathogens.[4-6]

Pathophysiology

Rhinosinusitis is typically caused by mucosal inflammation and mucociliary dysfunction from viral infection or allergy. Increased mucous production and reduced clearance lead to blockage of the sinus ostia. This environment is ideal for bacterial growth and promotes a cycle of local inflammation and mucosal injury characterized by increased concentrations of interleukins, interferons, and tumor necrosis factor.[31] Damage to the host defense system perpetuates bacterial overgrowth and persistence of infection.

Table 75–3

Risk Factors for Acute Bacterial Rhinosinusitis[6,29,30]

Allergic or nonallergic rhinitis
Anatomic defects (eg, septal deviation)
Aspirin allergy, nasal polyps, and asthma
Cystic fibrosis or ciliary dyskinesia
Dental infections or procedures
Immunodeficiency
Intranasal medications or illicit drugs
Mechanical ventilation
Nasogastric tubes
Swimming or diving
Tobacco smoke exposure
Trauma or barotrauma
Upper respiratory tract infection (predominant risk factor)
Winter season

Treatment

The goals of treatment are to relieve symptoms; promote sinus drainage; avoid unnecessary antibiotic use or, when appropriate, use safe and effective antibiotics to eradicate bacterial infection and minimize resistance development; and prevent development of chronic disease or complications.

▶ *General Approach to Treatment*

Initial management should focus on symptom relief and identification of patients with ABRS who are most likely to benefit from antibiotics. **KEY CONCEPT** Antibiotics should be prescribed only when ABRS is most likely and when the benefits of treatment outweigh the potential harms. ABRS is more likely than viral involvement alone in instances where symptoms persist without evidence of improvement for at least 10 days after the onset of illness; when

Clinical Presentation and Diagnosis of Acute Bacterial Rhinosinusitis

Signs and Symptoms[4-6]

- *Adults:* Purulent nasal and/or postnasal discharge *plus* nasal congestion/obstruction and/or facial pain, pressure, or fullness; diminished sense of smell; fever; cough; maxillary tooth pain; fatigue; ear fullness, pressure, or pain
- *Children:* Persistent nasal or postnasal drainage; nasal congestion and mouth breathing; persistent cough (particularly at night) or throat clearing; fever; pharyngitis; ear discomfort; halitosis; morning periorbital edema or facial swelling; fatigue; facial or tooth pain

Laboratory Tests

- *Laboratory studies/nasopharyngeal cultures:* not recommended
- *Radiographic studies:* Useful for assessing presence of complications
- *Paranasal sinus puncture:* "Gold standard"; not routine but can be useful in complicated or chronic cases

Complications

- Orbital cellulitis or abscess, periorbital cellulitis, meningitis, cavernous sinus thrombosis, ethmoid or frontal sinus erosion, chronic sinusitis, and exacerbation of asthma or bronchitis

Diagnosis[4-6]

- *Clinical diagnosis:* Most common method; signs and symptoms that persist *without evidence of improvement* for at least 10 days *or* that worsen after initial improvement *or* severe symptoms (fever ≥ 39.0°C [102.2°F] and purulent nasal discharge) for at least 3 to 4 days at illness onset. Respiratory secretion color is unreliable for diagnosis because neutrophil presence causes color and is found in viral sinusitis.[4]

symptoms suddenly worsen within 10 days after initial improvement; or when symptoms are severe (fever ≥ 39.0°C [102.2°F] and purulent nasal discharge) in the first 3 to 4 days of illness onset.[4-6]

▶ *Nonpharmacologic Therapy*

Humidifiers, nasal saline sprays or drops, and nasal saline irrigation devices moisturize the nasal canal, impair crusting of secretions, and promote mucociliary clearance. Although many patients report benefit from these therapies, few controlled studies exist to support their efficacy in acute sinusitis.[32] Nasal irrigation with isotonic or hypertonic saline may reduce medication use and improve symptoms, especially in patients with allergic rhinitis and recurrent or chronic sinusitis, and it has a low risk of adverse reactions.[32-34]

▶ *Pharmacologic Therapy*

Adjunctive Therapy Medications that target rhinosinusitis symptoms are commonly used despite a lack of published evidence supporting their efficacy.[4] Analgesics/antipyretics are used to treat facial pain and fever. Oral decongestants relieve congestion but should be avoided in children younger than 4 years and patients with ischemic heart disease or uncontrolled hypertension. Intranasal decongestants can be used for severe congestion in patients 6 years of age or older but use should be limited to 3 to 5 days to avoid rebound nasal congestion. Avoid antihistamines because they thicken mucus and impair clearance, but they may be useful in patients with allergic rhinitis or chronic sinusitis.[29] Similarly, intranasal corticosteroids usually are reserved for patients with allergies or chronic sinusitis, but they may be beneficial as monotherapy or with antibiotics in ABRS if the clinician and patient agree that their modest benefits after 15 to 21 days of use outweigh their cost and minor adverse effects (epistaxis, nasal itching, and headache).[4,5,35] Systemic corticosteroids modestly improve symptoms or resolution when given concurrently with antibiotics, but most studies enrolled adults with fewer than 10 days of symptoms.[36] There is no evidence to support the use of guaifenesin in ABRS.

Antibiotic Therapy Because diagnosis is usually based on clinical presentation, clinicians must differentiate ABRS from viral rhinosinusitis in order to minimize inappropriate antibiotic use. In addition, recent evidence suggests that ABRS resolves spontaneously in many cases. Studies in adults with clinically diagnosed nonsevere sinusitis report cure rates of nearly 50% at 7 days and 70% at 14 days with no statistical differences between antibiotics and placebo, but there are significantly more adverse effects with antibiotics (28%) as compared to placebo (15%).[4,37] Studies in children with persistent nasal discharge for at least 10 days report modest benefits with antibiotic therapy.[38] In some studies, antibiotics led to faster symptom resolution with lower failure rates compared with no treatment, particularly with more severe infection.[5,6]

Treatment guidelines outline management approaches that include observation with close follow up for uncomplicated infections (eg, those that do not extend beyond the sinuses or nasal cavity) or the use of antibiotics, depending on patient characteristics and illness presentation.[4-6] In adults, some experts recommend observation for up to 7 days after ABRS is diagnosed, but only through shared decision-making with patients and only if follow-up is available during this timeframe.[4] If symptoms worsen or fail to improve by 7 days after diagnosis, reevaluation should occur and antibiotics should be initiated (either with a repeat office visit or via use of a delayed antibiotic prescription). Alternatively, antibiotics may be prescribed at the time of diagnosis for adults who are willing to accept the risk of adverse effects and cost of therapy in exchange for the small benefit that antibiotics provide. Other experts recommend prompt antibiotic therapy in all patients when the diagnosis of ABRS is confirmed with the use of strict diagnostic criteria.[5] In children, 3 days of observation with close follow-up is an alternative approach for patients with persistent illness without symptom improvement for at least 10 days.[6] Severe or complicated infections should be treated in conjunction with specialists such as otolaryngologists or infectious diseases physicians.

Patient Encounter 2

A 50-year-old African American man presents to his primary care physician with purulent postnasal discharge, nasal congestion, headache, and ear fullness/pressure. He developed rhinorrhea and congestion 8 days ago while on his honeymoon in the Caribbean. After some initial improvement, his symptoms significantly worsened over the past 2 to 3 days. His wife had similar symptoms that started 1 day before his illness, but she recovered completely. He reports that he snorkeled and swam in the ocean frequently while in the Caribbean. He tried Dayquil LiquiCaps yesterday but received little to no relief. He has had two sinus infections in the past 5 years but has not taken antibiotics in the last 2 years.

Immunizations: Up to date with the exception of Tdap

Allergies: Tree and grass pollens; cat dander

Meds: Dayquil LiquiCaps (in each capsule: acetaminophen 325 mg, dextromethorphan 10 mg, phenylephrine 5 mg) two capsules every 6 hours as needed (he took two doses yesterday)

PE:

Gen: Tired-appearing, moderate distress, appears uncomfortable

VS: BP 120/70 mm Hg, P 82 beats/min, RR 14 breaths/min, T 38.2°C (100.7°F), Wt 81.8 kg (180 lb)

HEENT: Bilateral middle ear effusions; tympanic membranes dull with diminished light reflex; thick, purulent yellow–green postnasal discharge; nasal mucosal edema; frontal and maxillary facial tenderness upon palpation; no oral lesions; erythematous pharynx with no tonsillar hypertrophy

What information is suggestive of acute bacterial rhinosinusitis (ABRS)?

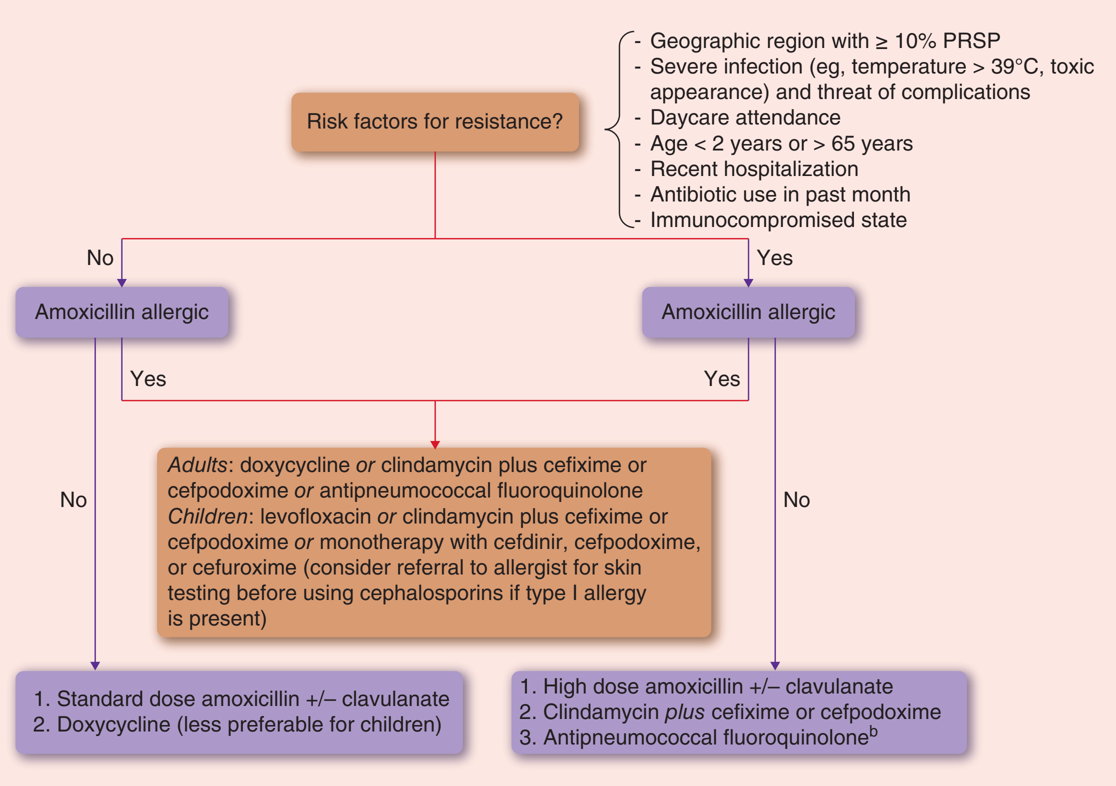
What risk factors are present?

What other diagnostic studies, if any, should be performed?

What are the treatment goals for this patient?

Create a care plan for this patient that includes nonpharmacologic and pharmacologic therapies and a monitoring plan.

When antibiotics are prescribed, empiric selection of an agent that is likely to result in favorable clinical and bacteriologic outcomes is recommended (Figure 75–3). Antibiotics (Table 75–4) should target *S. pneumoniae* and *H. influenzae*, but consideration must also be given to local resistance patterns and other bacteria. **KEY CONCEPT** Standard dose amoxicillin or amoxicillin–clavulanate is recommended for most patients.[4-6] Amoxicillin is effective for most infections and is less expensive and better



Risk factors for resistance?
- Geographic region with ≥ 10% PRSP
- Severe infection (eg, temperature > 39°C, toxic appearance) and threat of complications
- Daycare attendance
- Age < 2 years or > 65 years
- Recent hospitalization
- Antibiotic use in past month
- Immunocompromised state
No
Yes
Amoxicillin allergic
Amoxicillin allergic
Yes
Yes
No
No
Adults: doxycycline or clindamycin plus cefixime or cefpodoxime or antipneumococcal fluoroquinolone
Children: levofloxacin or clindamycin plus cefixime or cefpodoxime or monotherapy with cefdinir, cefpodoxime, or cefuroxime (consider referral to allergist for skin testing before using cephalosporins if type I allergy is present)
1. Standard dose amoxicillin +/– clavulanate
2. Doxycycline (less preferable for children)
1. High dose amoxicillin +/– clavulanate
2. Clindamycin plus cefixime or cefpodoxime
3. Antipneumococcal fluoroquinolone[b]

FIGURE 75–3. Treatment algorithm[a] for ABRS. [a]Antibiotics are listed in order of preference based on predicted clinical and bacteriologic efficacy rates, clinical studies, safety, and tolerability. Doses can be found in Table 75–4. [b]Antipneumococcal fluoroquinolone = levofloxacin, moxifloxacin.[4-6]

tolerated than amoxicillin–clavulanate, which provides expanded coverage against β-lactamase producers. Amoxicillin–clavulanate should be considered in patients who are at risk for infection with an amoxicillin-resistant organism, such as recent antibiotic use in the previous month, or if optimal coverage for β-lactamase–producing bacteria is desired. High-dose amoxicillin or amoxicillin–clavulanate is recommended for patients who are at high risk for infection from resistant bacteria, such as those who attend daycare, have moderate-to-severe illness, and when PRSP or other resistant bacteria are frequent in a community (Figure 75–3). Patients with penicillin allergies can be treated with an appropriate cephalosporin or doxycycline, depending on allergy severity. Cephalosporin monotherapy is less desirable because of increased pneumococcal resistance, so combination therapy with clindamycin may be required to optimize coverage for PRSP and β-lactamase producers, especially in moderate-to-severe illness.[4-6] Fluoroquinolones carry a risk of serious side effects that generally outweigh the benefits of treatment for ABRS. They should be reserved for patients who have no alternative treatment options and, when used, should have adequate antipneumococcal activity (eg, levofloxacin and moxifloxacin). Pregnant women who are allergic to beta-lactams can be treated with clindamycin, but this antibiotic only provides pneumococcal coverage. Doxycycline and fluoroquinolones should be avoided in pregnancy. Macrolides and trimethoprim–sulfamethoxazole are not recommended because of high pneumococcal and *H. influenzae* resistance. For uncomplicated infections, treatment duration ranges from 5 to 10 days in adults and 10 to

Patient Care Process for Acute Bacterial Rhinosinusitis

See Patient Care Process for Upper Respiratory Tract Infections.

Develop a Care Plan:

- If appropriate, select an antibiotic (see Figure 75–3) and optimal dose and duration (see Table 75–4).

Implement the Care Plan:

- Educate patient or patient's parent or caregiver that symptoms may resolve slowly and can be present for up to 7 days (or longer) after diagnosis, even when antibiotics are initiated.
- Manage patients with severe infection or complications in conjunction with otolaryngologists and/or infectious diseases physicians.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist beyond 7 days or worsen at any time.
- If patient does not respond to first- or second-line therapy, refer to an otolaryngologist or infectious diseases physician.
- If recurrent infections or chronic sinusitis develop, refer to an otolaryngologist.

Table 75–4

Antibiotics[a] for the Treatment of Acute Bacterial Rhinosinusitis[4-6]

Drug	Adult Dose	Pediatric Dose[b]	Relative Cost[c]	Comments
Amoxicillin	1.5–4 g/day divided in two to three doses	45–90 mg/kg/day divided in two doses	$	Lacks coverage against β-lactamase producers
Amoxicillin–clavulanate	1.5–4 g/day divided in two to three doses	45–90 mg/kg/day divided in two doses	$$–$$$	Broad coverage particularly with high doses; Augmentin XR (2 g every 12 hours) targeted toward PRSP
Cefdinir	600 mg/day divided in one to two doses	14 mg/kg/day divided in one to two doses	$$	Preferred oral liquid cephalosporin owing to good palatability
Cefixime	200 mg twice daily	8 mg/kg/day divided in two doses	$$$–$$$$	IDSA recommends use only in combination with clindamycin
Cefpodoxime proxetil	200 mg twice daily	10 mg/kg/day divided in two doses	$$$–$$$$	IDSA recommends use only in combination with clindamycin
Cefuroxime axetil	250–500 mg twice daily	15–30 mg/kg/day divided in two doses	$$–$$$	Only included as an option in AAP guideline; suspension no longer available in the United States
Ceftriaxone	1 g IM/IV every 24 hours	50 mg/kg IM/IV every 24 hours	$$$–$$$$	Experts recommend a 5-day treatment course; useful for patients who are vomiting and cannot tolerate oral therapy
Doxycycline	100 mg twice daily	4 mg/kg/day divided in two doses	$–$$$	Can cause photosensitivity and GI effects (abdominal pain, esophagitis, or esophageal ulcers); tooth staining in children younger than 8 years is unlikely with durations of therapy that are 21 days or less; many drug–drug interactions (antacids, iron, calcium)
Levofloxacin	500–750 mg once daily (750 mg × 5 days)	10 mg/kg/dose every 12–24 hours	$–$$$$	Common fluoroquinolone side effects are nausea, vaginitis, diarrhea, dizziness, photosensitivity; many drug–drug interactions (antacids, iron, calcium); serious side effects (tendon rupture, muscle or joint pain, confusion, hallucinations, neuropathies, hypoglycemia, QT prolongation, aortic ruptures or tears) limit their broad utility for ABRS
Moxifloxacin	400 mg once daily	Not available	$$–$$$	
Clindamycin	300–450 mg three times daily	30–40 mg/kg/day divided in three doses	$–$$$	No Gram-negative coverage; use only in combination with cephalosporin

[a]Refer to Table 75–2 for more information on antibiotics. Other FDA-approved antibiotics for ABRS not included in the Infectious Diseases Society of America, American Academy of Pediatrics, or American Academy of Otolaryngology-Head and Neck Surgery Foundation guidelines: azithromycin, cefaclor, cefprozil, clarithromycin, ciprofloxacin, erythromycin, and trimethoprim–sulfamethoxazole.

[b]Maximum dose not to exceed adult dose.

[c]Approximate cost per course: $ (under $25), $$ ($25–$50), $$$ ($50–$100), $$$$ (over $100).

AAP, American Academy of Pediatrics; ABRS, acute bacterial rhinosinusitis; IDSA, Infectious Diseases Society of America; IM, intramuscular; PRSP, penicillin-resistant *S. pneumoniae*.

14 days in children.[4-6] While short-course therapy with some fluoroquinolones and β-lactams are as effective as longer courses in adults with uncomplicated ABRS, data are lacking to support shorter courses in more severe infections or in children.[39]

Failure to improve within 7 days of therapy or worsening at any time requires reevaluation to confirm the diagnosis, consider changing antibiotics, and examine for complications.[4]

Outcome Evaluation

Clinical improvement (eg, defervescence, reduced nasal congestion, and discharge, improvements in pain or facial pressure) should be evident within 7 days of therapy. Monitor for common adverse effects and refer to a specialist if clinical response is not obtained with first- or second-line therapy. Referral is also important for severe, recurrent, or chronic infection. Surgery may be indicated in complicated cases.

PHARYNGITIS

Pharyngitis is an inflammation of the throat often caused by infection. Most infections are viral and self-limited, but antibiotics are frequently prescribed because of difficulty in clinically distinguishing between viral and bacterial infection and the fear of untreated streptococcal illness.

Epidemiology and Etiology

Pharyngitis is a common manifestation of viral URIs. *Streptococcus pyogenes* (Group A streptococci) is the most common bacterial cause, responsible for 20% to 30% of cases in children and 5% to 15% of adult infections.[7,40] It is most common in late winter and early spring and spreads easily through direct contact with contaminated secretions. Children between 5 and 15 years have the highest incidence of streptococcal pharyngitis. Clusters of infection are common within families, classrooms, and other crowded settings. Although rarer than *S. pyogenes*, *Fusobacterium necrophorum* is becoming more common among adolescents and young adults.[41] This pathogen is associated with pharyngitis and lymphadenopathy, but it can progress to more serious findings including peritonsillar abscesses and jugular venous thrombophlebitis (Lemierre's syndrome).

Pathophysiology

Group A streptococcal pharyngeal colonization occurs in up to 20% of children and is a risk factor for developing pharyngitis if

Clinical Presentation and Diagnosis of Streptococcal Pharyngitis

Signs and Symptoms of Streptococcal Pharyngitis[7,40]

- Abrupt onset of sore throat and severe pain while swallowing
- Fever
- Headache, abdominal pain, nausea, or vomiting (especially in children)
- Tonsillopharyngeal erythema with or without exudates
- Tender, anterior cervical lymphadenitis
- Swollen erythematous uvula
- Halitosis
- Soft palate petechiae
- Scarlatiniform rash
- Absence of conjunctivitis, hoarseness, cough, rhinitis, discrete ulcerations, and diarrhea (suggestive of viral etiology)
- Centor criteria: tonsillar exudates; tender anterior cervical adenopathy; fever; absence of cough

Complications

- Nonsuppurative: acute rheumatic fever, scarlet fever, streptococcal toxic shock syndrome, poststreptococcal glomerulonephritis or reactive arthritis, pediatric autoimmune neuropsychiatric disorder associated with group A streptococci (PANDAS)
- Suppurative: peritonsillar or retropharyngeal abscesses, cervical lymphadenitis, otitis media, sinusitis, necrotizing fasciitis

Diagnosis[7,40]

- Tests should be performed *only* when there is clinical suspicion for streptococcal pharyngitis. The likelihood of having streptococcal infection increases with the number of Centor criteria that are present. Centor criteria are most useful for identifying patients for whom testing and antimicrobial therapy are unnecessary (ie, fewer than three criteria). Pharyngeal streptococcal carriage occurs in up to 20% of healthy children.
- Rapid antigen detection test (RADT): 70% to 90% sensitivity; results available within minutes.
- Throat culture: "gold standard"; results available within 24 to 48 hours. Should be performed after all negative RADTs in children and adolescents; consider in adults with significant pediatric contact. Also recommended in outbreaks and to monitor for resistance.
- Rapid polymerase chain reaction (PCR) test: point-of-care test with results in 15 minutes or less; if sensitivity is 97% or more, negative result does not require follow-up throat culture. These point-of-care tests can be used in community pharmacies along with treatment algorithms to expand access to patients without leading to antibiotic overuse.[42,43]

there is disruption in mucosal integrity.[7] Symptoms of streptococcal pharyngitis usually are self-limited and resolve within a few days of onset *without* antibiotic treatment.[7] Historically, untreated or inappropriately treated infection caused acute rheumatic fever, heart valve damage, and other infectious complications. Antibiotic therapy given up to 9 days after symptom onset can prevent these sequelae. Proper diagnosis of streptococcal pharyngitis is important to minimize inappropriate antibiotic use for viral infections and prevent complications of untreated streptococcal infection.[7,40]

Treatment

KEY CONCEPT The goals of therapy for streptococcal pharyngitis are to shorten the disease course, reduce spread, and prevent complications. Certain immune-mediated complications such as glomerulonephritis and reactive arthritis are not impacted by antibiotics.[7]

▶ *Nonpharmacologic Therapy*

Pain and throat irritation are key features of pharyngitis. Consumption of warm fluids, such as tea or soup, or cold items, such as ice chips or popsicles, can soothe dry throat tissue and provide hydration. Food items that coat the throat, such as honey or hard candies, can provide temporary relief of throat pain. Environmental approaches, such as adjusting room humidity to avoid a dry environment and avoiding smoke exposure, and warm saline gargles can also relieve throat irritation.

▶ *Pharmacologic Therapy*

Adjunctive Therapy Oral analgesics provide pain relief within 1 to 2 hours and can allow patients to maintain normal eating and drinking habits. Topical therapies, including medicated lozenges or sprays, provide quicker but temporary relief of throat pain and can be used in conjunction with oral analgesics. There is no evidence to support enhanced efficacy of one type of lozenge or spray over another; however, benzocaine should be avoided because of rare but serious reports of methemoglobinemia associated with benzocaine sprays.

Antibiotic Therapy **KEY CONCEPT** Antibiotics should be used only in cases of laboratory-confirmed streptococcal pharyngitis with associated clinical symptoms (Figure 75–4).[7,40] Effective therapy (Table 75–5) reduces the infectious period from approximately 10 days to 24 hours and results in clinical improvement in 1 to 2 days.[2,7,40] **KEY CONCEPT** Penicillin is the drug of choice because it is the only antibiotic studied for prevention of acute rheumatic fever, in addition to its narrow spectrum, documented safety and efficacy in nasopharyngeal streptococcal eradication, and low cost.[7,40] Amoxicillin is an alternative agent, particularly for children because of its improved taste and its enhanced adherence with once-daily dosing.[7,40] Cephalosporins may be more effective than penicillin for relapse prevention and nasopharyngeal eradication, particularly in asymptomatic carriers and adults.[44] Cephalosporins can be used in patients with non–type I penicillin allergies (eg, maculopapular rash) and preference should be given to first-generation agents that are more narrow in spectrum. Azithromycin or clindamycin can be used in patients with severe penicillin reactions (eg, anaphylaxis, angioedema, or serious delayed reactions).[7,40] Usual duration of therapy is 10 days, but shorter courses of cefpodoxime, cefdinir, and azithromycin are Food and Drug Administration (FDA)-approved.

Resistance plays a smaller role in pharyngitis treatment compared with other URIs. **KEY CONCEPT** Penicillin resistance is

[b]It is the clinician's discretion to perform a throat culture in adults who have a negative RADT.[7,40]

Table 75–5

Antibiotics[a] for the Treatment of Streptococcal Pharyngitis[7,39]

Drug	Adult Dose	Pediatric Dose[b]	Duration	Relative Cost[c]	Comments
Penicillin V	500 mg two to three times daily	250 mg two to three times daily (if ≤ 27 kg); 500 mg two to three times daily (if > 27 kg)	10 days	$	Drug of choice but increasing reports of treatment failures
Penicillin G benzathine	1.2 million units	600,000 units (if ≤ 27 kg); 1.2 million units (if > 27 kg)	1 IM dose	$$$$	Useful for patients with poor adherence or emesis; painful injection but pain can be reduced if warmed to room temperature prior to administration
Amoxicillin	500 mg twice daily or 1 g once daily	50 mg/kg once daily; max 1 g	10 days	$	Preferred drug for young children because of improved palatability and once-daily dosing
Cephalexin	500 mg twice daily	25–50 mg/kg/day divided in two doses	10 days	$	Recommended in non–type I penicillin allergy
Cefadroxil	1 g once daily	30 mg/kg once daily	10 days	$–$$	Recommended in non–type I penicillin allergy
Cefdinir	300 mg twice daily or 600 mg once daily	14 mg/kg/day divided in one to two doses	5–10 days	$$	Broad spectrum; can be used in non–type I penicillin allergy
Azithromycin	500 mg once daily	12 mg/kg once daily; 12 mg/kg on day one, then 6 mg/kg once daily for 4 days	3 days (5 days for children)	$–$$	Recommended in severe penicillin hypersensitivity; increasing resistance
Clindamycin	300 mg three times daily	20 mg/kg/day divided in three doses	10 days	$–$$$	Recommended in severe penicillin hypersensitivity; useful for recurrent infections

[a]Other FDA-approved agents include amoxicillin–clavulanate, cefixime, cefaclor, cefprozil, cefpodoxime, cefuroxime, erythromycin, and clarithromycin.

[b]Maximum dose not to exceed adult dose.

[c]Approximate cost per course: $ (under $25), $$ ($25–$50), $$$ ($50–$100), $$$$ (over $100).

IM, intramuscular.

Patient Encounter 3

A 7-year-old Hispanic boy presents to an urgent care clinic with a sore throat and fever of 39.0°C (102.2°F) that have been present for 12 hours. He says his "throat stings," and he is refusing to eat or drink. He has no other symptoms and takes no medications on a regular basis. His father gave him acetaminophen 4 hours ago, but it did not provide much relief. He has no known drug allergies. His father reports that the child's 9-year-old sister has recurrent episodes of "strep throat," but she is currently healthy with no symptoms. The child has no known sick contacts. Physical examination reveals pharyngeal and tonsillar erythema, enlarged tonsils with white exudates, and tender cervical lymphadenopathy.

Does this child have streptococcal pharyngitis?

Is antibiotic therapy indicated? If so, what agent should be initiated and for how long?

What education should be provided to his father regarding treatment?

extremely rare in group A streptococci, but resistance and clinical failures occur more frequently with tetracyclines, trimethoprim–sulfamethoxazole, and to a lesser degree macrolides. Recurrent infections or treatment failures can be retreated with the same initial antibiotic or treated with amoxicillin–clavulanate, a cephalosporin, clindamycin, or penicillin G benzathine.[7,40]

Outcome Evaluation

Antibiotics relieve symptoms of streptococcal pharyngitis within 3 to 5 days, and patients can return to work or school if improved after the first 24 hours of therapy. A lack of improvement or worsening after 72 hours of therapy requires reevaluation. Follow-up throat cultures are not recommended unless symptoms persist or recur. Recurrent symptoms following an appropriate treatment course should prompt reevaluation for possible retreatment.

COMMON COLD

The common cold is a viral URI associated with a significant health care burden, including medical visits, work or school absenteeism, and widespread use of cough and cold medication for treatment or prevention.[45,46] Clinicians must be aware of evidence regarding the use of cough and cold products in order to make appropriate recommendations for this commonly encountered condition.

Epidemiology and Etiology

Many viruses cause the common cold, including rhinoviruses (most common), coronaviruses (including severe acute respiratory syndrome coronavirus 2, or SARS-CoV-2), parainfluenza viruses, respiratory syncytial virus, and adenoviruses. Infection rates increase during the fall through spring seasons and are highest in the winter months. Adults experience 1 to 3 colds each year, whereas children have 6 to 11 colds per year.[45,46] Colds usually resolve over 10 to 14 days but can be complicated by bacterial superinfections, including AOM and ABRS. Factors associated with an increased incidence of colds are young age, daycare attendance, contact with school-age children, crowded conditions and poorly ventilated areas, cigarette smoke exposure, and inadequate physical or mental rest. Children are more likely than adults to transmit viruses because of poorer hand hygiene, closer casual contacts, and sharing of toys. Viral antigenic drifts and host immune system evasion contribute to the persistence of URIs in the community.

Pathophysiology

Viruses enter the respiratory tract mucosa via inhalation of aerosols or infected droplets or direct contact with contaminated secretions. After cell entry, viral replication and shedding occur for several days to weeks. Symptoms arise from epithelial cell damage, inflammation, vasodilation, local tissue edema, increased mucous production, and impaired mucociliary clearance. Tracheobronchial inflammation and irritation induce cough via afferent nerve impulse transmission to the medulla. Antibody production halts viral replication and inflammation as symptoms diminish.

Patient Care Process for Streptococcal Pharyngitis

See Patient Care Process for Upper Respiratory Tract Infections.

Assess the Information:

- If streptococcal pharyngitis is likely, perform an RADT or rapid PCR test (and follow-up throat culture, if necessary) to confirm the diagnosis.
- Determine if antibiotic therapy is indicated based on diagnostic testing (see Figure 75–4).

Develop a Care Plan:

- If streptococcal pharyngitis is confirmed with laboratory testing, select antibiotic therapy that is likely to be effective and safe (Table 75–5).

Implement the Care Plan:

- Educate patient or patient's parent or caregiver that symptoms should improve within 1 to 2 days and resolve completely within 3 to 5 days with appropriate antibiotic therapy (if streptococcal pharyngitis is confirmed).
- Discuss the need to avoid close contact with others for 24 hours to minimize spread.
- Discuss the importance of medication adherence to treat infection, minimize spread, and reduce chances of recurrence.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist after 72 hours or worsen at any time.
- Reevaluate patient if symptoms recur after completion of therapy.

Clinical Presentation and Diagnosis of the Common Cold

Symptoms typically begin 24 to 72 hours after infectious contact. They peak at day 3 to 5 of illness, begin to wane by day 7, and usually resolve by day 10 to 14.

Signs and Symptoms[45,46]

- *Onset:* Malaise, fatigue, headache, pharyngitis, mildly elevated temperature (can be higher in infants and children)
- *Secondary:* Nasal and/or postnasal drainage (often clear at onset but can become thick and purulent); congestion; cough and/or throat clearing; sneezing; conjunctivitis; irritability; impaired smell or taste
- *Coronavirus disease (COVID-19):*[47] Causes a wide range of signs and symptoms, from asymptomatic infection to severe illness (see Lower Respiratory Tract Infections chapter); common presentation includes fever and/or chills, cough, shortness of breath, new loss of smell and/or taste, fatigue, myalgias, headache, sore throat, congestion and/or rhinorrhea, nausea or vomiting, diarrhea

Complications

- AOM, ABRS, chronic bronchitis, bronchiolitis (in infants and children < 2 years), laryngotracheobronchitis (croup), pneumonia, asthma exacerbation

Diagnosis

- *Clinical diagnosis:* Most common method; based on history, presence of symptoms, and physical examination
- *Radiographic studies:* Useful for assessing complications such as pneumonia
- *Laboratory studies:* Rapid viral antigen detection tests or real-time reverse transcription PCR tests of nasopharyngeal samples may be helpful for epidemiology and diagnosis in acute and severe illness; authorized SARS-CoV-2 tests include nasopharyngeal, oropharyngeal, nasal mid-turbinate, anterior nares, or saliva specimens[47]

Treatment

The treatment goal is to minimize discomfort from symptoms to allow patients to function as normally as possible. Preventative measures are also important to limit the spread of infection. Antibiotics are not effective, but they are often prescribed to patients with viral URIs and purulent secretions, which have contributed to increased resistance.[1,2] Treatment should focus on symptom relief.

▶ *Nonpharmacologic Therapy*

Supportive measures include air humidification, intranasal saline drops or sprays with or without bulb suctioning, nasal saline irrigation, increased fluid intake, throat lozenges or saline gargles, and rest. Nasal strips may relieve congestion by lifting the nares and opening the anterior nasal passages. Honey may provide relief of cough symptoms in childen, but it should not be used in infants because of the risk of botulism.[48] These nondrug measures are particularly useful for children younger than 6 years and pregnant women, for whom medication safety is a significant concern. Although studies proving their benefits are lacking, these nondrug treatments are safe.

▶ *Pharmacologic Therapy*

Nonprescription cough and cold preparations are used frequently despite a lack of evidence to support their safety and efficacy. Reports of serious adverse events and deaths led to efforts to eliminate the use of these medications in young children.[48,49]

Patient Encounter 4

A 48-year-old Caucasian woman presents to her primary care provider's office with a "sinus infection." 3 days ago, she developed a scratchy, mild sore throat and clear rhinorrhea. Her throat pain has improved, but today her nasal discharge is thicker and brownish in color and she is moderately congested. She used intranasal phenylephrine this morning, which provided relief but only for a few hours. She also feels more tired than usual and has a mild headache. She has seasonal allergic rhinitis and migraines, but she has not had a migraine for 2 years. She is divorced with two daughters (19 years of age and 15 years of age); the youngest daughter has similar symptoms.

Immunizations: Up to date; needs influenza vaccine this season

Allergies: Trimethoprim–sulfamethoxazole (rash); ragweed

Meds: Cetirizine 10 mg once daily during allergy season (fall); intranasal fluticasone propionate one spray each nostril daily during allergy season (fall); rizatriptan 10 mg orally as needed for migraine headaches; *Echinacea purpurea* 400 mg three times daily (started this morning); intranasal phenylephrine 1% two sprays in each nostril every 6 hours as needed (started this morning; has used one time only)

PE:

Gen: No apparent distress

VS: BP 102/62 mm Hg, P 62 beats/min, RR 12 breaths/min, T 37.1°C (98.8°F), Wt 57.3 kg (126 lb)

HEENT: Conjunctiva clear; no photophobia; brown nasal and postnasal discharge with swollen nasal mucosa; mildly erythematous pharynx; mild pain upon frontal palpation; tympanic membranes dull appearing bilaterally

Lungs: Clear to auscultation; no crackles

What signs and symptoms are suggestive of the common cold? Which are suggestive of ABRS?

What diagnostic studies should be performed?

Create a care plan that includes nonpharmacologic and pharmacologic therapies and a monitoring plan. Include preventative measures in your plan.

Manufacturers have removed product labeling for all children younger than 4 years. Hundreds of products are available to manage cold symptoms. **KEY CONCEPT** Choice of therapy is influenced by patient age, presence of comorbid conditions, and balance of effectiveness and safety. Single-ingredient agents are preferred to target only symptoms that are present and to minimize toxicity that can result from confusion and a lack of knowledge about active ingredients in multiple ingredient formulations. Cautious use of nonprescription products is warranted in certain patient populations: pregnant or lactating women, children, elderly, and patients with cardiovascular disease, diabetes, or glaucoma. Table 75–6 summarizes some of the available agents used for cold symptoms. Antipyretics and analgesics are used for fever, pain, and discomfort. Local anesthetics (eg, phenol, dyclonine) temporarily relieve throat pain and are available in lozenges and sprays. Decongestants cause vasoconstriction that can improve congestion, but the use of intranasal products should be limited to 3 to 5 days to avoid rebound congestion.

Table 75–6

Select Nonprescription Medications for the Common Cold for Patients 6 Years of Age and Older[42–44]

Class/Drug	Adults and Children > 12 Years of Age	Children 6–12 Years of Age[a]	Comments
Analgesics/Antipyretics			
Acetaminophen[b,c]	325–650 mg every 4–6 hours as needed or 1000 mg every 6 hours as needed (max 3.25 g/day or 4 g/day if directed by health care provider); extended-release 1300 mg every 8 hours as needed (max 3.9 g/day)	10–15 mg/kg/dose every 4–6 hours as needed (max 5 doses/day and not to exceed 4 g/day)	Use with caution in preexisting liver disease; monitor acetaminophen dose from all sources (prescription, nonprescription, and combination products); some experts recommend a maximum dose of 3 g/day in adults
Ibuprofen[d]	200–400 mg every 4–6 hours as needed (max 1200 mg/day)	4–10 mg/kg/dose every 6–8 hours as needed (max 4 doses/day and maximum single dose of 400 mg)	Use with caution in cardiovascular disease and those with history of peptic ulcer disease or GI bleeding; avoid use in elderly, renal impairment, and heart failure; avoid in third trimester of pregnancy
Decongestants			
Intranasal:			
Oxymetazoline 0.05%[c]	Two to three sprays every 12 hours as needed (max 2 doses/24 hours)	One to two sprays every 12 hours as needed (max 2 doses/24 hours)	Limit use of intranasal decongestants to 3–5 days to minimize risk of rebound congestion; use with caution in patients with cardiovascular disease, diabetes, hyperthyroidism, or prostatic hypertrophy
Phenylephrine 0.25%, 0.5%, 1%	Two to three sprays no more than every 4 hours as needed	One to three sprays no more than every 4 hours as needed (0.25% only)	
Systemic:			
Pseudoephedrine	60 mg every 4–6 hours as needed; extended release 120 mg every 12 hours or 240 mg every 24 hours as needed (max 240 mg/day)	30 mg every 4–6 hours as needed (max 120 mg/day)	Avoid use in patients with cardiovascular disease; children and elderly have increased risk of adverse effects (cardiovascular or CNS stimulation); use with caution in patients with diabetes, hyperthyroidism, prostatic hypertrophy; avoid in first trimester of pregnancy
Phenylephrine	10 mg every 4 hours as needed (max 60 mg/day)	5 mg every 4 hours as needed (max 30 mg/day)	
Cough Suppressants			
Dextromethorphan[c]	10–20 mg every 4 hours or 20–30 mg every 6–8 hours as needed; extended release 60 mg twice daily as needed (max 120 mg/day)	10 mg every 4 hours as needed; extended release 30 mg twice daily as needed (max 60 mg/day)	Increased adverse effects in children and poor metabolizers (5%–10% of Caucasians; 2% in African Americans and Asians); can cause dysphoria and serotonin syndrome; use caution in those taking psychotropic medications
Expectorants			
Guaifenesin	200–400 mg every 4 hours as needed; extended release 600–1200 mg every 12 hours as needed (max 2.4 g/day)	100–200 mg every 4 hours as needed (max 1.2 g/day)	May cause nausea and abdominal pain, particularly in high doses
Anticholinergics			
Intranasal ipratropium 0.06%[c]	Two sprays 3–4 times/day	Two sprays 3 times/day	Used for rhinorrhea only; does not improve congestion, postnasal drip, or sneezing; can cause epistaxis and nose/mouth dryness

[a] Maximum dose not to exceed adult dose.

[b] Preferred antipyretic/analgesic for children; can be used in newborns.

[c] Safe to use in pregnancy.

[d] Can be used in children older than 6 months of age.

Antihistamines should generally be avoided: first-generation agents can dry secretions through their anticholinergic effects, but they impair mucociliary clearance of thick mucus, which can worsen congestion, and there is not a clear benefit for cough or cold symptoms when these agents are used alone.[45,46,48] When used in combination with decongestants, certain antihistamines may provide some improvement in symptoms in adults and older children only but not in young children.[48] Cough suppressant use is not supported by strong evidence showing benefit.[42,44] They can cause significant neurologic adverse effects and have been linked to abuse by teens for their euphoric effects in high doses.[49] Guaifenesin, an expectorant, may reduce sputum thickness in adults, but it has been poorly studied in children.[48,50] Regular high-dose vitamin C (> 200 mg/day) supplementation may result in mild reductions in cold severity or duration, but it is most useful for prevention in patients exposed to intense physical exercise/training or cold stress.[51] Echinacea has limited benefit for treatment in adults, and its use is discouraged for prevention and in all children because of adverse effects including gastrointestinal distress and rash.[52] It should also be avoided in patients with allergies to ragweed, daisies, chrysanthemums, or marigolds because of the risk of cross sensitivity. Zinc lozenges are not consistently effective, but when used within 24 hours of symptom onset, they may slightly reduce the duration and severity of cold symptoms.[45,46,48]

Prevention

Prevention of the common cold is best achieved by minimizing contact with infected people and secretions. Frequent hand washing with soap and water or the use of an alcohol-based hand sanitizer (at least 60% alcohol) is vital. Coughing or sneezing into the elbow should be taught rather than using tissues or covering the mouth and nose with hands. Other methods that are advocated for preventing the spread of viruses include smoking cessation, maintenance of a healthy lifestyle through diet and exercise, and minimizing stress. Specific mitigation strategies for preventing the spread of COVID-19 include wearing a mask that covers the mouth and nose, staying at least 6 ft away from people who do not co-reside, avoiding crowds and poorly ventilated indoor spaces, and frequent hand washing.

While most colds cannot be prevented with vaccines, there are two viral vaccines available to prevent respiratory tract infections: influenza (please see Lower Respiratory Tract Infections, Chapter 74) and COVID-19. In response to the COVID-19 pandemic, the FDA provided Emergency Use Authorization (EUA) of two mRNA vaccines for use in the United States in December 2020 and a recombinant viral vector vaccine in February 2021.[53] The mRNA vaccines encode the prefusion spike glycoprotein of SARS-CoV-2 whereas the recombinant vaccine is a replication-incompetent adenovirus expressing the SARS-CoV-2 spike protein. These vaccines have been shown to be highly effective in preventing hospitalization and death from COVID-19.[53] Each vaccine has different authorized age-groups for use, administration schedules, and storage requirements and are not considered interchangeable. Expected postvaccination symptoms include local reactions (eg, pain, swelling, erythema, and axillary lymphadenopathy) and systemic reactions (eg, fever, chills, fatigue, headache, myalgia, and arthralgia) in most patients.[53] These reactions are usually mild to moderate, occur in the first few days, and resolve within 1 to 3 days of onset. They are more common after the second dose (for mRNA vaccines) and occur more frequently in younger patients (< 55 years of age). Hypersensitivity and anaphylaxis have been rarely reported, in addition to myocarditis and pericarditis in adolescents and young adults (mRNA vaccines) and blood clots with low platelets in women younger than 50 years of age (viral vector vaccine). These vaccines may be given to individuals with underlying medical conditions, including immunocompromised states, autoimmune conditions, or history of Guillain–Barre syndrome or Bell's palsy, as long as no contraindications are present. The Centers for Disease Control and Prevention (CDC) considers the following to be contraindications to the COVID-19 vaccines: severe allergic reaction (eg, anaphylaxis) or immediate allergic reaction of any severity after a previous dose of the vaccine or any of its components (including polyethylene glycol); or an immediate allergic reaction of any severity to polysorbate.[53] Although there are limited data, women who are pregnant or lactating can choose to be vaccinated after weighing the benefits and the risks. With the rapid changes in the COVID-19 pandemic, health care providers must stay abreast of current vaccine recommendations as additional information becomes available and new vaccines are authorized for use.

Outcome Evaluation

Most colds resolve within 7 to 10 days. Monitor patients for persistent symptoms lasting longer than 10 to 14 days, worsening symptoms, and complications such as wheezing, difficulty breathing, significant facial or ear pain, and high fevers. If complications are suspected, refer to a clinician for evaluation.

Patient Care Process for Common Cold

See Patient Care Process for Upper Respiratory Tract Infections

Assess the Information:

- Based on patient history, review of systems, and physical examination, determine if the presentation is consistent with the common cold.
- Determine if pharmacologic therapy is indicated or if nonpharmacologic measures alone can be employed.

Develop a Care Plan:

- Select nonpharmacologic and/or nonprescription therapies that will provide optimal relief of symptoms and that are safe for the patient.

Implement the Care Plan:

- Educate patient or patient's parent or caregiver that symptoms may resolve slowly and can be present for up to 10 to 14 days. If symptoms persist without improvement for longer than 10 days or worsen, refer the patient for medical evaluation.
- Discuss preventative measures for minimizing spread and future illnesses.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist beyond 10 to 14 days or worsen at any time.
- If complications develop such as wheezing, difficulty breathing, significant facial or ear pain, or high fevers, refer to a clinician for evaluation.

Abbreviations Introduced in This Chapter

ABRS	Acute bacterial rhinosinusitis
AOM	Acute otitis media
OME	Otitis media with effusion
PRSP	Penicillin-resistant *S. pneumoniae*
RADT	Rapid antigen detection test
URI	Upper respiratory tract infection

76 Skin and Skin Structure Infections

Jaime R. Hornecker and Lauren R. Biehle

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Discuss skin structure and function responsible for preventing infection.
2. Describe the epidemiology, etiology, pathogenesis, diagnostic criteria, and clinical manifestations associated with acute bacterial skin and skin structure infections (ABSSSIs).
3. Identify goals of therapy associated with clinical response in patients with ABSSSI.
4. Recommend effective empiric and definitive antimicrobial regimens when given a diagnosis, patient history, physical examination, and laboratory findings.
5. Monitor chosen antimicrobial therapy for safety and efficacy.
6. Apply the Patient Care Process to the management of a patient with ABSSSI.

INTRODUCTION

Skin and skin structure infections, also known as acute bacterial skin and skin structure infections (ABSSSIs), are frequently encountered in both acute and ambulatory care settings and account for a significant number of outpatient visits and hospitalizations annually.[1] ABSSSIs range in severity from mild, superficial, and self-limiting to life-threatening deep tissue infections requiring intensive care, surgical intervention, and intravenous (IV) broad-spectrum antibiotics. Gram-positive pathogens, primarily *Staphylococcus aureus* and *Streptococcus* species, are the most common causative bacteria.[2-5] Polymicrobial infections are more likely in complicated or deeper infections and in persons with immune suppression, diabetes, vascular insufficiency, or recent surgery.[2,5]

The role of methicillin-resistant *S. aureus* (MRSA), particularly community-acquired MRSA (CA-MRSA), in ABSSSI is of increasing importance. In many US cities, MRSA is the most frequently isolated pathogen from patients presenting to emergency departments with ABSSSI, and antimicrobial prescribing has largely shifted toward empiric use of MRSA-active agents.[3] Historically, MRSA infections were associated with healthcare exposure or defined populations such as injection drug users or athletes[4,6]; however, despite some modest decline in the proportion of *S. aureus* isolates in recent years, a high MRSA prevalence in the community means that risk stratification may be more difficult to perform. In areas with high rates of CA-MRSA, and in patients with recurrent infections or infections that persist despite appropriate antimicrobial therapy, empiric therapy, including antibiotics active against MRSA, must be considered.[2,7] The general management of ABSSSIs is discussed throughout this chapter.

Intact skin generally is resistant to infection. In addition to providing a mechanical barrier, its relative dryness, slightly acidic pH, colonizing bacteria, frequent desquamation, and production of various antimicrobial defense chemicals, including sweat (which contains IgG and IgA), prevent invasion by various microorganisms.[8] Conditions predisposing patients to ABSSSIs include trauma to the skin, alterations in vascularization, and oxygenation leading to decreased skin perfusion, fluid stasis, and altered immune function impairing the body's ability to fight infection.[9]

IMPETIGO

EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT Impetigo is a common skin infection that can occur in any age-group but most frequently affects children between 2 and 5 years. β-Hemolytic streptococci (*Streptococcus pyogenes* or Group A *Streptococcus* [GAS]) and *S. aureus* are the most common pathogens.[5] Impetigo is a superficial infection and spreads easily, especially in settings of poor hygiene and crowding, and particularly during summer months. The offending microorganisms colonize the skin surface and invade through abrasions, insect bites, or trauma. The crusty eruption of impetigo ensues. These lesions may occur anywhere on the body but are most common on the face and extremities.[7]

CLINICAL PRESENTATION AND DIAGNOSIS

Impetigo lesions are numerous, well localized, and **erythematous**. **KEY CONCEPT** They begin as small, thin-walled blisters that quickly evolve into ruptured lesions, with the dried discharge forming a honey-colored crust reminiscent of cornflakes.[5,7] Impetigo lesions are rarely painful but are **pruritic**. Scratching the lesions can spread the infection to other areas of the body. Scarring is rarely problematic, unless ulceration occurs, as in ecthyma.[5]

In order to avoid further spread and complications, antibiotic therapy is usually indicated. Sequelae of impetigo are uncommon. Rare manifestations of disease include transformation into cellulitis, progression to sepsis requiring hospitalization, or development of glomerulonephritis secondary to GAS.[5]

TREATMENT

The primary goals of impetigo therapy include preventing infection spread within the patient and to others, infection resolution, and preventing recurrence. Secondarily, symptom relief (eg, itching) and improving cosmetic appearance are important. Prevention of the rare but serious complications of impetigo is an alternative goal.[10]

Nonpharmacologic Treatment

Because impetigo is rarely painful, there is often a delay in seeking medical attention. Lesions may improve with time and increased hygiene along with soaking and cleansing lesions with mild soap and water. The use of skin emollients to dry skin areas may reduce spread and urge to scratch itchy lesions. The use of natural remedies is controversial; however, tea tree oil and Manuka honey may provide some anecdotal benefit.[10]

Pharmacologic Treatment

Antibiotic therapy is recommended to prevent spread of infection and complications. Although GAS historically has been the primary causative organism and penicillin is recommended when cultures yield streptococci alone, KEY CONCEPT the incidence of S. aureus impetigo is common, and oral penicillinase–stable penicillins (such as dicloxacillin) or first-generation cephalosporins (such as cephalexin) are preferred. In skin cultures of children with impetigo, MRSA rates have only ranged from 7% to 10% of cases (other cases were due to GAS or MSSA). Clindamycin, sulfamethoxazole–trimethoprim, or doxycycline is preferred for the treatment of MRSA impetigo. These are also alternative choices when penicillin allergy is a concern; however, tetracyclines should be avoided in children younger than 8 years. KEY CONCEPT Topical antimicrobials are also effective in some cases of impetigo. Topical mupirocin or retapamulin twice daily for 5 days may be used alone in mild cases with few lesions or in individual outbreaks.[5,10] Ozenoxacin is a topical nonfluorinated quinolone antibiotic that was recently approved for treatment of impetigo in patients greater than 2 months of age. It has activity against MRSA and *S. pyogenes*. Ozenoxacin applied twice daily for 5 days may be effective in impetigo resistant to other topical antimicrobials, though mupirocin remains first line in most cases.[11]

FOLLICULITIS, FURUNCLES, AND CARBUNCLES

See Table 76–1 for summary.

CELLULITIS AND ERYSIPELAS

EPIDEMIOLOGY AND ETIOLOGY

Cellulitis and erysipelas are common bacterial infections involving the skin, with over 14 million cases annually.[12] KEY CONCEPT Cellulitis is an infection of the dermis and subcutaneous tissue, whereas erysipelas is a more superficial infection of the upper dermis and superficial lymphatics. Although both can occur on any part of the body, many infections involve the leg.[12,13] These infections develop after a break in skin integrity, resulting from trauma, surgery, ulceration, burns, tinea infection, or other skin disorder. However, they may occur after an inapparent break in the skin. In rare cases, cellulitis develops from blood-borne or contiguous spread of pathogens.[5]

Etiologic microorganisms vary according to the area involved, host factors, and exposures. KEY CONCEPT The predominant pathogens associated with cellulitis are streptococci, mainly Group A, and less frequently S. aureus, including methicillin-resistant strains. Persons who are immunocompromised, have diabetes or vascular insufficiency, or use injection drugs are at risk of polymicrobial cellulitis.[5]

CLINICAL PRESENTATION AND DIAGNOSIS

The manifestations of nonpurulent infections are compared to purulent infections as shown in Table 76–2.

With early diagnosis and appropriate therapy, the prognoses of cellulitis and erysipelas are excellent. Severe or repeated episodes can cause lymphedema. Blood cultures are often obtained, but the actual rate of bacteremia is difficult to determine, and the yield may be low since cellulitis is often treated empirically.[12] Patients at higher risk of bacteremia from cellulitis include those with malignancy, signs of systemic infection (such as fever), animal bites, and immunocompromised. Rare complications include the spread of infection to deeper skin and soft tissue layers and sepsis.[5]

Annual recurrence rates, especially for cellulitis of the leg, can be as high as 20%[5], and over 50% within 3 years from the initial infection.[13] Cases often recur at the same site as previous infections. Vascular and lymphatic insufficiencies increase the risk of recurrences; obesity, tobacco use, history of cancer, and homelessness also increase risk.[5]

TREATMENT

The goals of therapy for cellulitis and erysipelas are rapid and successful eradication of the infection and prevention of related complications.

Nonpharmacologic Treatment

Nonpharmacologic treatment includes elevating the involved limb to decrease swelling. Sterile saline dressings may be placed on open lesions to cleanse them of purulent materials. Surgical debridement may be indicated for severe infection and to assess for necrotizing infection. Incision and drainage of abscesses is imperative to achieving clinical cure and may be the only treatment necessary if abscesses are small (< 5 cm) with limited cellulitis.[5] The choice to treat with antibiotics after incision and drainage of an uncomplicated abscess is controversial.

Pharmacologic Treatment

Many patients with erysipelas or cellulitis are effectively treated with outpatient therapy. Hospitalization and treatment with IV antibiotics is recommended in the presence of systemic inflammatory response syndrome (SIRS) (eg, temperature $> 38°\text{C}$ or $< 36°\text{C}$, tachypnea > 24 breaths/min, tachycardia > 90 beats/min, or white blood cell $> 12 \times 10^3/\text{mm}^3$ $[12 \times 10^9/\text{L}]$ or $< 400/\text{mm}^3$ $[0.4 \times 10^9/\text{L}]$), altered mental status, or hemodynamic instability. Patients presenting with sepsis based on the Sepsis-3 definition and Sequential (Sepsis-related) Organ Failure Assessment (SOFA) should also be candidates for hospitalization and broad-spectrum antimicrobials.[12,14] Further, inpatient therapy should be considered when suspecting deep or necrotizing infections, severely immunocompromised patients, failure of outpatient therapy, or poor adherence to therapy.[5]

Antibiotic choices for nonpurulent cellulitis should have activity against streptococci and include penicillin, amoxicillin, amoxicillin–clavulanate, dicloxacillin, cephalexin, or clindamycin. In the inpatient setting, empiric intravenous options include penicillin, ceftriaxone, cefazolin, or clindamycin.[5] Monotherapy with a β-lactam is appropriate in uncomplicated cases.[15,16]

Table 76–1

Folliculitis, Furuncles, and Carbuncles

	Folliculitis	Furuncles	Carbuncles
Epidemiology/ etiology	**KEY CONCEPT** Folliculitis is a superficial inflammatory reaction involving the hair follicle. The most familiar form of folliculitis is acne. It can be infectious, caused by microorganisms such as Staphylococcus aureus, *Pseudomonas, and Candida.*	Also known as boils, furuncles might be described as a deep form of folliculitis. A furuncle is a bacterial infection that has spread into the subcutaneous skin layers but still only involves individual follicles. Furuncles occur primarily in young men. Diabetes and obesity are other predisposing factors. *Staphylococci* are the most common cause.	Carbuncles share all the characteristics of furuncles. However, a carbuncle is larger and involves several adjacent follicles and may extend into the subcutaneous fat. Carbuncles are more likely to occur in patients with diabetes and tend to form on the back of the neck.
Presentation and diagnosis	Folliculitis presents as small, pruritic, erythematous papules. Location of the lesions and patient history are often all that are required in the diagnosis of folliculitis. Although Gram stain and culture of the papules may be considered, they are not generally required as folliculitis typically resolves spontaneously.	Furuncles most commonly develop on the face, neck, axilla, and buttock. A furuncle typically starts as a small, red, tender nodule. Within a few days, the nodule becomes painful and pustular. Typically, a furuncle will spontaneously discharge pus, heal and leave a small scar.	Carbuncles are similar to furuncles; only they are larger and exquisitely painful.
Desired outcomes	The goals of therapy for folliculitis, furuncles, and carbuncles are resolution of infection with no or minimal scarring. A secondary goal of therapy for larger furuncles and all carbuncles is to minimize the risk of endocarditis or osteomyelitis by reducing bloodstream invasion.		
Nonpharmacologic treatment	**KEY CONCEPT** Warm compresses are generally sufficient.	*Moist heat is indicated to facilitate drainage. Large furuncles require incision and drainage.*	*Incision and drainage are indicated.*
Pharmacologic treatment	**KEY CONCEPT** Often resolves spontaneously. A topical antibiotic or antifungal may be used to control the spread of infection but generally is unnecessary. For staphylococcal or streptococcal folliculitis, antibiotic ointments such as mupirocin might be administered. Antifungal shampoo can be used for **dermatophytes**.	*Carbuncles and furuncles that are purulent with signs of infection (ie, fever) should be treated systemically with an antibiotic that will cover S. aureus, such as dicloxacillin or cephalexin. Trimethoprim–sulfamethoxazole or doxycycline is preferred if CA-MRSA is suspected or if the patient has a severe allergy to penicillin.* Treatment should continue until acute inflammation has resolved, usually a 5- to 10-day course. Immunocompromised patients and severe infections or abscesses in patients who fail incision and drainage plus oral antibiotics should be treated empirically with vancomycin, daptomycin, linezolid, or ceftaroline. Prevention for recurrent episodes may be warranted, including adequate skin hygiene with the use of soap and water and handwashing after contact with lesions. Proper care of clothing and dressings is also recommended to prevent autoinoculation.	

Data from Refs. [5,7].

However, when purulent drainage, abscess, or ulcer is present, or in cases of penetrating trauma, particularly IV drug use, antibiotics with activity against MRSA should be initiated.[5]

Vancomycin continues to be the drug of choice for severe cellulitis due to MRSA because of its efficacy, safety, and low cost. Daptomycin, linezolid, or ceftaroline are also acceptable and should be considered over vancomycin when the isolated organism has a minimum inhibitory concentration (MIC) of greater than 2 mcg/mL (eg, vancomycin-intermediate *S. aureus* [VISA] or vancomycin-resistant *S. aureus* [VRSA]).[17] Newer agents for

Patient Encounter 1, Part 1: Cellulitis

A 76-year-old man presents to the emergency department with a 6-day history of progressively worsening pain and swelling of his left lower extremity. Upon examination, you notice that in addition to the patient's complaints, the area is visibly erythematous. The left lower extremity also seems to have significant hyperpigmentation and evidence of chronic venous insufficiency/venous stasis when compared to the right lower extremity. When questioned, he says that his legs have ranged from pink to purple to red in color. He reports running a low-grade fever and some feelings of fatigue but otherwise feels fine. His vital signs in the emergency department reveal a temperature of 38.9°C, pulse 96 beats/min, blood pressure 142/89 mm Hg, and respiratory rate 18 breaths/min. The physician diagnoses the patient with cellulitis, and he is admitted to the inpatient care team.

What subjective and objective clinical manifestations are suggestive of cellulitis?

What additional information do you need before developing a therapeutic plan for this patient?

Table 76–2

Characteristics of Nonpurulent and Purulent ABSSSI

	Nonpurulent	Purulent
Clinical manifestation	Cellulitis, erysipelas	Abscess, carbuncle, furuncle
Initial presentation	Diffuse redness, edema, warmth, and tenderness	Painful and tender localized lesion
Microbiology	Often unable to obtain culture from infected area Blood cultures considered in complicated or severe cases	Often able to obtain culture data from localized lesion Blood cultures considered in complicated or severe cases
Nonpharmacologic management	Incision and drainage not recommended	Incision and drainage recommended
Common causative pathogens	Streptococcus *pyogenes*	*Staphylococcus aureus*, including MRSA

[a] Modified from Ref. [5] (Figure 1) and Ref. [12].

ABSSSI, including tedizolid, dalbavancin, and oritavancin, may have advantages over traditional therapy in terms of duration of activity and administration.[12,18,19] Delafloxacin is a broad-spectrum fluoroquinolone with activity against MRSA approved for ABSSSI.[20] Omadacycline is an aminomethylcycline (tetracycline-derivative) antibiotic that has activity against Gram-positive, Gram-negative, atypical, and anaerobic organisms.[21] Both delafloxacin and omadacycline are available orally and intravenously. Cost and availability may limit the use of these newer agents.

For less severe, uncomplicated infections, many CA-MRSA strains can be treated with clindamycin (isolates resistant to erythromycin should be evaluated with a D test), doxycycline, or trimethoprim–sulfamethoxazole.[5,17] Trimethoprim–sulfamethoxazole and doxycycline should be empirically combined with a β-lactam if GAS is also a suspected causative organism, since the activity of these agents against β-hemolytic streptococci is unknown.[5] Linezolid is an additional oral option approved for ABSSSI with activity against MRSA and streptococci. It is available in both intravenous and oral formulations. It should be avoided in combination with medications that have serotonin or monoamine oxidase activity as it can precipitate serotonin syndrome.[22]

KEY CONCEPT In addition to coverage for staphylococcal and streptococcal ABSSSI, patients with severe infections should receive treatment for gram-negative bacilli such as Escherichia coli and Pseudomonas aeruginosa, with or without anaerobic coverage. Empiric broad-spectrum antimicrobial coverage, including coverage for resistant organisms such as healthcare-associated MRSA (HA-MRSA) and *P. aeruginosa*, is appropriate for severe ABSSSI and/or severe systemic illness. Broad-spectrum antimicrobials, including activity against gram-negative bacteria, can also be considered in individuals who are neutropenic, receiving chemotherapy, or have immunodeficiency.[5] Vancomycin with an antipseudomonal β-lactam (ie, piperacillin–tazobactam, cefepime, meropenem) is recommended in these cases. Empiric therapy continuation is recommended in polymicrobial infections, whereas more defined therapy is recommended when a causative pathogen is isolated.[5]

Patient Encounter 1, Part 2: Cellulitis: Medical History, Physical Examination, and Diagnostic Tests

PMH: Hypertension, type 2 diabetes mellitus (last A1c of 9.6%), and transient ischemic attack.

FH: Father's family history unknown. Mother passed away at 72 years of age due to complications of coronary artery disease.

SH: Denies alcohol or tobacco use. Daily use of marijuana. Lives alone, retired.

Meds: Lisinopril 10 mg PO daily, aspirin 81 mg PO daily, metformin 1000 mg PO BID, glipizide 5 mg PO BID, atorvastatin 40 mg PO daily.

Allergies: No known drug allergies.

ROS: (+) chills, fatigue, erythema, and swelling of lower extremity; (–) headache, chest pain, shortness of breath, cough, nausea, vomiting, diarrhea, and weight loss.

PE:

Gen: Patient is an obese male who is alert, awake, and oriented. Wt 118 kg (260 lb); Ht 5′7″ (170 cm). BMI=40.7.

Chest: Lungs bilaterally clear to auscultation.

CV: Regular rate, rhythm. No murmurs/rubs/gallops.

Ext: Left lower extremity with significant erythema and hyperpigmentation. Left lower extremity warm to touch and tender to palpation. He has sensation to light touch in bilateral lower extremity and is able to move toes bilaterally. One small ulcer on left lower ankle that appears to be chronic, no purulence. Right lower extremity within normal limits.

Imaging:

Foot X-ray of left lower extremity: Diffuse soft tissue swelling of the foot and ankle. No subcutaneous gas or foreign body. No fracture or arthritic change.

Tibia–fibula X-ray of left lower extremity: No definitive fracture or other bone abnormalities identified.

Labs: WBC 17.8 × 10^3/mm^3 (17.8 × 10^9/L), serum creatinine 1.2 mg/dL.

What are the most likely causative organisms in this case of cellulitis?

What subjective or objective clinical criteria would be concerning for necrotizing fasciitis in this patient's presentation rather than the diagnosis of cellulitis?

What are the goals of therapy for this patient?

What antimicrobial therapy would you recommend? Include drug, dosage, route, interval, and duration of therapy.

How would you monitor your selected regimen for safety and efficacy?

Table 76–3

Empiric Antimicrobial Therapy for Cellulitis

Host Factors	Probable Etiologic Bacteria	Mild Infection or Step-Down Therapy[a] (Oral Antibiotic Therapy)	Moderate–Severe Infection[a] (IV Antibiotic Therapy)
Previously healthy	MSSA GAS MRSA	Dicloxacillin 500 mg every 6 hours Cephalexin 500 mg every 6 hours Clindamycin 300–600 mg every 6–8 hours CA-MRSA suspected or allergy to PCNs: Clindamycin[b] 300–600 mg every 6–8 hours Trimethoprim–sulfamethoxazole DS[c] one to two tablets every 12 hours Doxycycline[c] 100 mg every 12 hours Linezolid 600 mg every 12 hours	Nafcillin 1–2 g every 4 hours Cefazolin 1–2 g every 8 hours Clindamycin 600–900 mg every 8 hours CA-MRSA suspected or allergy to PCNs: Vancomycin 15–20 mg/kg every 8–12 hours (individualize dose to achieve a trough of 15–20 mcg/mL or AUC:MIC 400-600 mg·h/L) Linezolid 600 mg every 12 hours Daptomycin 4 mg/kg every 24 hours Ceftaroline[f] 600 mg every 12 hours
Immunocompromise, diabetes mellitus, vascular insufficiency, pressure ulcer infection, or other polymicrobial infection suspected	MSSA MRSA Enterobacteriaceae *Pseudomonas aeruginosa* Anaerobes	Amoxicillin–clavulanate[d] 875 mg every 12 hours Levofloxacin[e] 750 mg every 24 hours + clindamycin 300–600 mg every 6 hours Moxifloxacin[d] 400 mg every 24 hours	Vancomycin, daptomycin, or linezolid, in combination with one of the following choices: Piperacillin–tazobactam[e] 4.5 g every 6 hours Ampicillin–sulbactam 3 g every 6 hours Imipenem–cilastatin[e] 500 mg every 6 hours Ertapenem 1 g every 24 hours Meropenem 1 g every 8 hours Cefepime[e] 2 g every 8 hours ± metronidazole 500 mg every 8 hours Ceftazidime[e] 2 g every 8 hours + clindamycin 600–900 mg every 8 hours OR Ceftaroline 600 mg every 12 hours + clindamycin 600–900 mg every 8 hours or metronidazole 500 mg every 8 hours

[a] Doses given are for adults with normal renal function. IV therapy can be switched to oral therapy (as for mild infection) when the patient is afebrile and signs of infection are resolving. Extended infusion of β-lactams can be considered per protocol of individual institution.

[b] CA-MRSA isolates resistant to erythromycin should be evaluated for inducible clindamycin resistance via a D test.

[c] Limited clinical data exist for the treatment of MRSA infections. Poor activity against GAS; consider using in combination with clindamycin or cephalexin if empiric coverage for GAS is desired.

[d] If CA-MRSA suspected, clindamycin, trimethoprim–sulfamethoxazole, or doxycycline must be added to this regimen.

[e] *P. aeruginosa* generally is susceptible to this agent.

[f] Use caution in patients with known hypersensitivity to β-lactam antibiotics.

[g] MRSA coverage is indicated for patients with severe cellulitis or systemic illness, who have risk factors for HA-MRSA or CA-MRSA infection or reside in areas with high CA-MRSA prevalence. Otherwise, the broad-spectrum regimens listed below, without MRSA coverage, are appropriate.

Data from Refs. [5,7,12].

Table 76–3 lists some recommended antibiotic regimens for the treatment of ABSSSI. Because antimicrobial susceptibilities vary considerably between geographic locations, clinicians should select empiric treatment based on the antibiograms at their respective institutions. To decrease spread of resistance, antibiotic therapy should be narrowed based on culture and sensitivity results whenever possible. The duration of therapy for uncomplicated cellulitis typically ranges from 5 to 10 days. For complicated cellulitis, therapy with IV antibiotics is generally initiated, and a switch to oral therapy can be made once the patient is afebrile and skin findings begin to resolve. Typically, this is done after 3 to 5 days.[5,23] The complete duration of therapy may extend beyond 10 days if the patient's infection has a slower clinical response within the first 5 days.[5]

Recurrent cellulitis can be problematic, and reducing risk factors, such as obesity, edema, or toe abnormalities, may help with prevention, especially in the lower extremities. For patients with recurrent abscesses due to *S. aureus*, decolonization regimens can be considered. These include intranasal mupirocin, chlorhexidine rinses, and decontamination of towels or sheets. Efficacy of

Patient Encounter 1, Part 3: Cellulitis: Clinical Course

During the patient's hospitalization, he becomes afebrile. No microbiology data is available as the presentation is primarily diffuse redness without purulence. On day 4 of the patient's hospital stay, his cellulitis has significantly improved. The interdisciplinary team of clinicians is preparing the patient for discharge.

What would you suggest for modification of his antimicrobial regimen to an oral regimen?

What is the appropriate duration of his antibiotic course of therapy for his cellulitis?

How would you monitor his new regimen for safety and efficacy?

What are the patient's risk factors for recurrence of his cellulitis?

What strategies would you recommend to prevent recurrence of cellulitis?

decolonization has not been consistently proven to reduce rates of ABSSSIs.[5] Low-dose antibiotic prophylaxis with penicillin or erythromycin for up to 1 year may reduce recurrences, but the benefit subsides when therapy is discontinued and is not routinely recommended.[5,13] When edema is present, the use of compression stockings may decrease recurrent cellulitis.[24]

NECROTIZING FASCIITIS

EPIDEMIOLOGY AND ETIOLOGY

Necrotizing fasciitis (NF) is a rapidly progressive, life-threatening infection causing necrosis of subcutaneous tissue and fascia. When due to GAS infection, its associated mortality rate approaches 25%.[25] NF can affect any age-group. Although the risk of NF is higher in injection drug users and patients with diabetes or vascular insufficiency, healthy hosts can become infected as well.[5]

NF typically erupts after an initial trauma, which can range from a small abrasion to a deep penetrating wound. The infection begins in the fascia, where bacteria replicate and release toxins facilitating spread. Patients' pain is often out of proportion with the visible injury.[5]

NF may be monomicrobial, most often involving *S. pyogenes, S. aureus, Vibrio vulnificus,* or *Aeromonas hydrophila*. Polymicrobial NF may develop in the following clinical settings: after surgery or deep penetrating wounds involving the bowel; from decubitus ulcer, perianal, or vulvovaginal infection; or from the injection site in an IV drug user.[5]

CLINICAL PRESENTATION AND DIAGNOSIS

Patient outcomes rely on the clinician's ability to recognize NF early in the course of disease. This is often difficult because early disease tends to be indistinguishable from cellulitis. The clinical presentation of NF is presented in Table 76–4.

Table 76–4

Presentation of Necrotizing Fasciitis

Symptoms
- Early: Severe pain that is disproportionate to clinical signs and extends beyond the margins of the infected area.
- Late: Area may become numb secondary to muscle and nerve involvement.

Signs
- Early: Skin is erythematous, edematous, and warm; the clinical presentation is similar to that of cellulitis.
- Intermediate (within 24–48 hours): Blisters and bullae indicate severe skin and tissue ischemia.
- Late: The skin becomes violaceous and progressively gangrenous, and subcutaneous tissues have wooden-hard induration; hemorrhagic bullae may be present. Systemic signs may include fever, tachycardia, hypotension, and shock.

Laboratory Tests
- White blood count, serum creatinine, and C-reactive protein may be elevated.
- Deep tissue specimens obtained during surgical irrigation and debridement should be sent for Gram stain, culture, and sensitivity.

Imaging Studies
- MRI and CT scans may reveal fluid and gas along fascial planes.
- Typically, imaging studies are avoided when making a diagnosis because they may delay surgical intervention and increase mortality.

NF, necrotizing fasciitis.

Data from Refs. [5,26].

NF is perhaps the most devastating ABSSSI. Left untreated, it can invade the muscles and circulation, resulting in myonecrosis and septic shock, respectively. Many cases caused by GAS are accompanied by GAS toxic shock–like syndrome. The syndrome is bacterial exotoxin mediated and can be very evasive and highly lethal.[26] Amputation is common in patients with extremity infections. Once the patient recovers from acute NF, he or she often requires skin and/or muscle grafting and consequent physical rehabilitation depending on the amount and types of tissues removed during surgical intervention and the duration of hospital stay.[27]

TREATMENT

The goals of therapy for NF include eradication of infection and reduction of related morbidity and mortality.

Nonpharmacologic Treatment

KEY CONCEPT After resuscitation and hemodynamic stabilization, prompt surgical intervention is the key in the treatment of NF. Delayed operative debridement increases mortality, and most patients should return to the operating room frequently until debridement is no longer indicated.[5,27]

Pharmacologic Treatment

As an adjunct to surgery, high-dose, broad-spectrum IV antibiotic therapy should be initiated immediately in patients with NF until the patient has improved clinically and is afebrile for 48 to 72 hours, and no further need for debridement exists. Piperacillin–tazobactam, a carbapenem, ceftriaxone plus metronidazole, or a fluoroquinolone plus metronidazole is appropriate for empiric therapy. These agents should be used in combination with vancomycin, daptomycin, or linezolid until MRSA infection is ruled out.[5] Protein synthesis inhibitors, clindamycin or linezolid, are often utilized to decrease bacterial toxin production, thereby limiting tissue damage. This is particularly beneficial in streptococcal or clostridial infections.[28]

IV immunoglobulin (IVIG) dosed at 2 g/kg (ideal body weight) may also be a useful adjunctive treatment in patients with GAS NF who present with shock. Anecdotal evidence and data from small studies strongly support its use in improving 30-day survival and reducing mortality, although additional evidence is needed for a definitive recommendation.[5]

DIABETIC FOOT INFECTIONS

EPIDEMIOLOGY AND ETIOLOGY

Foot ulcers and related infections are among the most common, severe, and costly complications of diabetes mellitus. The lifetime risk of developing at least one foot ulcer in persons with diabetes is estimated at 30%.[29,30] Diabetic foot infections (DFIs) are the main risk factor for limb amputation, and in addition to significant morbidity and impact on quality of life, the healthcare costs associated with treating infected foot ulcers are enormous.[30]

KEY CONCEPT Staphylococci and streptococci are the predominant pathogens in acutely infected diabetic foot ulcers. *However, severe or more extensive chronically infected wounds are subject to polymicrobial infection*. Clinicians should suspect Gram-negative (such as *P. aeruginosa*) and possibly low-virulence pathogens (including enterococci and *Staphylococcus epidermidis*) in polymicrobial

Patient Encounter 2, Part 1: Diabetic Foot Infection

A 47-year-old woman presents to the emergency department with complaints of pain, redness, and swelling of her right foot. When she had her last visit with her primary care provider 11 months ago, she was told that she had a small ulcer on her big toe, which she thought had healed. As she moves to the exam table, she has difficulty walking because the foot is so painful. Upon examination, you see what appears to be a chronic, deep lesion on the plantar aspect of her right great toe approximately 3 cm (1.2 in.) in diameter, and a smaller, more superficial ulcer near the heel. Her foot is erythematous, warm, and she has lymphangitic streaking extending beyond her ankle up into the calf. The patient has poorly controlled type 1 diabetes mellitus and indicates difficulty affording her insulin because she lost her job 6 months ago. She also has neuropathy that has affected the sensation in her lower extremities. The patient is afebrile, and other vital signs are within normal limits.

What signs and symptoms present in this patient are indicative of a diabetic foot infection?

Based on presentation, classify this patient's diabetic foot infection using the PEDIS grading scale.

What additional information do you need before developing a therapeutic plan for this patient?

infections. Foul-smelling, necrotic, or gangrenous wounds are also commonly infected with anaerobic bacteria. MRSA may be isolated in up to 30% of DFIs and may be more common in patients recently hospitalized or treated with broad-spectrum antibiotics, or those with a previous history of MRSA infection.[31-33]

PATHOPHYSIOLOGY

KEY CONCEPT The pathogenesis of diabetic foot infection stems from multiple key factors, including repetitive shear stress, peripheral neuropathy, altered immune function, and, when present, ischemia from peripheral vascular disease.[30] **Neuropathy**, the most prominent risk factor for diabetic foot ulcers, develops when continuously high blood glucose levels damage motor, autonomic, and sensory nerves. Damage to motor neurons that supply the small intrinsic muscles of the foot causes deformation, resulting in altered muscular balance, abnormal areas of pressure on tissues and bone, and repetitive injuries. Damage to autonomic neurons results in the shunting of blood through direct arteriole-venous communications, thereby decreasing capillary flow. The secretion of sweat and oil is also diminished, producing dry, cracked skin that is more prone to infection. Finally, damage to sensory neurons produces a loss of protective sensation so that the patient becomes unaware of injury or ulceration.[30,34]

Persons with diabetes have altered immune function that predisposes them to infection. Leukocyte function and cell-mediated and humoral immunity are compromised in poorly controlled disease.[31] Achieving and maintaining controlled blood glucose levels should be a component of the prevention and management of diabetic foot infections.

Finally, peripheral arterial disease can nearly double the risk of DFI and contributes to poorer outcomes.[34] The presence of other

Patient Encounter 2, Part 2: Diabetic Foot Infection: Medical History, Physical Examination, and Diagnostic Tests

PMH: Type 1 diabetes mellitus × 39 years, hypertension, microalbuminuria, dyslipidemia, migraine headaches, and Celiac disease.

FH: Father alive with type 2 diabetes, hypertension, dyslipidemia, and gout at age 70. Mother died at age 61 from hemorrhagic stroke. One brother alive with hypertension. One sister died at age 44 from breast cancer.

SH: Divorced, one daughter age 26. Formerly a teller at a bank, currently unemployed. Smokes six cigarettes/day. Denies alcohol use. Tries to eat a gluten-free diet.

Meds: NPH 70/30 14 units BID, enalapril 20 mg BID, rosuvastatin 20 mg daily, sumatriptan 100 mg at onset of headache and repeated at 2 hours prn.

Allergies: penicillin (hives).

ROS: (+) right foot findings per HPI; (–) headache, chest pain, shortness of breath, cough, nausea, vomiting, diarrhea, and weight loss.

PE:

Gen: Patient is in no acute distress. Wt 79 kg (143.8 lb); Ht 5 ft 5 in (165.1 cm).

Chest: CTAB.

CV: RRR. No murmurs/rubs/gallops.

Ext: 3-cm purulent, erythematous lesion present on the plantar aspect of the right great toe. 2+ edema in the left foot; diminished sensation bilaterally. Lymphangitic streaking present; wound probe 1.5 cm deep.

Labs: Most recent labs were drawn at last outpatient visit 11 months ago: BUN 15 mg/dL, SCr 1.1 mg/dL, Glu 212 mg/dL, A1C 10.6%.

The patient is diagnosed with a diabetic foot infection and is admitted to the hospital.

Explain the role of neuropathy, ischemia, and immunopathy in the development of this patient's diabetic foot infection.

What are the best preventative strategies for diabetic foot infections and complications such as lower extremity amputation?

Antimicrobial therapy for this patient's infection should provide coverage for which microorganisms?

What antimicrobial therapy would you recommend? Include drug, dosage, route, interval, and duration of therapy.

How would you monitor your selected regimen for safety and efficacy?

risk factors, including hypertension, dyslipidemia, and smoking, can cause vasoconstriction, and together, ischemia and skin breakdown can occur as a cumulative result. In addition to managing blood glucose levels, encouraging smoking cessation and managing other risk factors of cardiovascular disease is imperative.

CLINICAL PRESENTATION AND DIAGNOSIS

Not all diabetic foot ulcers are infected. However, infection is often difficult to detect when perfusion and the inflammatory response are limited in the patient with diabetes. The common signs and symptoms (ie, pain, erythema, and edema) of infection may be absent.[34] Still, the diagnosis of diabetic foot infection depends mostly on clinical evaluation.

Purulent drainage from the ulcer is indicative of infection. When pus and inflammatory symptoms are not present, the clinician must be astute to more subtle findings. These include delayed healing, increase in lesion size, prolonged exudate production, malodor, and tissue friability. Abnormal granulation tissue also may be present, as evidenced by color change (from bright red to dark red, brown, or gray) and increased bleeding. The ability to probe the ulcer to the underlying bone is highly indicative of osteomyelitis.[34]

Diabetic foot infections are classified into four categories based on clinical presentation using the PEDIS scale (perfusion, extent/size, depth/tissue loss, infection, sensation). Grade 1 signifies no infection; grade 2, involvement of skin and subcutaneous tissue only; grade 3, extensive cellulitis or deeper infection; and grade 4, the presence of systemic inflammatory response syndrome.[31,35] Table 76–5 provides detailed information regarding these grades.

Table 76–5

Clinical Classification of a Diabetic Foot Infection

Infection Severity	PEDIS Grade	Clinical Manifestations of Infection
Uninfected	1	Wound lacking purulence or any manifestations of inflammation
Mild	2	The presence of at least two manifestations of inflammation (purulence or erythema, pain, tenderness, warmth, or induration), but any cellulitis/erythema extends no more than 2 cm around the ulcer, and infection is limited to the skin or superficial subcutaneous tissues; no other local complications or systemic illness
Moderate	3	Infection (as above) in a patient who is systemically well and metabolically stable but who has at least one of the following characteristics: cellulitis extending > 2 cm, lymphangitic streaking, spread beneath the superficial fascia, deep tissue abscess, gangrene, and involvement of muscle, tendon, joint, or bone
Severe	4	Infection in a patient with systemic toxicity or metabolic instability (eg, fever, chills, tachycardia, hypotension, confusion, vomiting, leukocytosis, acidosis, severe hyperglycemia, or azotemia)

From Lipsky BA, Berendt AR, Cornia PB, et al. 2012 Infectious Diseases Society of America clinical practice guideline for the diagnosis and treatment of diabetic foot infections. Clin Infect Dis. 2012;54(12)132–173.

Patient Encounter 2, Part 3: Diabetic Foot Infection: Clinical Course

The patient received the empiric therapy you recommended for her diabetic foot infection. Two days later, deep wound cultures were reported positive for *MRSA*. Blood cultures revealed no growth. The patient remained hospitalized for an additional week, during which time her cellulitis improved on directed antimicrobial therapy. She was discharged to complete her antibiotic therapy and follow up as an outpatient in 1 week.

What modifications would you make to this patient's antimicrobial regimen knowing that the causative agent is MRSA?

What individualized foot care strategies can you suggest to this patient to prevent further infections?

Another DFI grading system, SINBAD, is based on clinical examination only and may simplify communication when triage is necessary. SINBAD evaluates site of infection, degree of ischemia based on palpation of pulse, the presence of neuropathy and bacterial infection, and area and depth of involvement. Other scoring systems may further predict amputation risk and benefit from revascularization.[35]

Imaging studies, such as X-ray and magnetic resonance imaging (MRI), can identify osteomyelitis. Blood cultures should be obtained from all patients with signs and symptoms of systemic illness. Deep tissue cultures may help to direct therapy. Bone also may be sent for culture in cases of osteomyelitis. Superficial cultures of ulcers are unreliable and should be avoided.[31]

Spreading soft tissue infection and osteomyelitis are often the first complications that develop from diabetic foot infection. Some patients develop bacteremia and sepsis. The most feared complication of infected diabetic foot ulcers is lower extremity amputation.[34]

TREATMENT

The goals of therapy for diabetic foot infection are eradication of the infection and avoidance of soft tissue loss and amputation.

Prevention

Comprehensive foot care programs and the utilization of multidisciplinary care teams can improve outcomes and decrease amputation rates.[31] Periodic foot examinations with monofilament testing and patient education regarding proper foot care, optimal glycemic control, and smoking cessation are key preventative strategies.

Nonpharmacologic Treatment

The nonpharmacologic treatment of diabetic foot ulcers may include debridement of necrotic or nonviable tissue, wound dressings, vascular or orthopedic surgery, and off-loading pressure from the wound.[31]

Pharmacologic Treatment

The severity of a patient's infection, based on the PEDIS scale, can help guide the selection of empiric antimicrobial therapy. Although most patients with grade 2 diabetic foot infections can be treated as outpatients with oral antimicrobial agents, all

Table 76–6

Empiric Pharmacologic Treatment of Diabetic Foot Infection

Infection Severity	PEDIS Grade	General Approach to Empiric Pharmacologic Treatment	Examples of Appropriate Empiric Antibiotics[a]
Uninfected	1	None. Avoid treating uninfected diabetic foot ulcers.	Not applicable
Mild	2	Oral, narrow-spectrum antibiotic therapy with activity against *Staphylococcus aureus* and streptococcal species. Include coverage for MRSA according to patient history and resistance patterns in the area. Duration of antibiotics: 1–2 weeks, may extend to 4 weeks if slow resolution	MRSA not suspected: cephalexin, dicloxacillin, clindamycin, amoxicillin–clavulanate, levofloxacin MRSA suspected: clindamycin[b], trimethoprim–sulfamethoxazole[c], doxycycline[c], or linezolid
Moderate	3	Difficult to define a general approach. In many patients, highly bioavailable oral therapy is appropriate. IV therapy should be initiated in patients with more extensive or chronic infections, or those with abscess, deep tissue, bone involvement, or gangrene. Duration of antibiotics: 1–3 weeks	Options for grade 3 infections: amoxicillin–clavulanate or ampicillin–sulbactam, cefoxitin, ceftriaxone, ertapenem, levofloxacin[d] + clindamycin, or moxifloxacin MRSA suspected: clindamycin[b], doxycycline[c], linezolid, daptomycin, trimethoprim–sulfamethoxazole[c], or vancomycin
Severe	4	Parenteral, broad-spectrum antibiotic therapy should be initiated. Ideally, drugs with activity against Gram-positive, Gram-negative, and anaerobic bacteria (especially if wound is malodorous) should be selected. Include coverage for MRSA. Duration of antibiotics: 2–4 weeks	IV options for grade 3–4 infection: gram-negative/anaerobic activity: ampicillin–sulbactam, aztreonam, cefepime, ceftazidime, ceftriaxone, ertapenem, imipenem–cilastatin[d], piperacillin–tazobactam, meropenem, moxifloxacin, levofloxacin[d] + clindamycin MRSA activity: vancomycin, daptomycin, or linezolid

[a] Please refer to Table 76–3 for dosing in adults with normal renal function.

[b] CA-MRSA isolates resistant to erythromycin should be evaluated for inducible clindamycin resistance via a D test.

[c] Poor activity against GAS; consider using in combination with clindamycin or cephalexin if empiric coverage for GAS is desired.

[d] *Pseudomonas aeruginosa* generally is susceptible to this agent.

Data from Refs. [29,31,34].

grade 4 and many grade 3 infections require hospitalization, stabilization of the patient, and broad-spectrum IV antibiotic therapy.[31,34]

Multiple antibiotic options exist for the treatment of diabetic wound infections. Table 76–6 provides both general treatment strategies and specific, although not all-inclusive, antibiotic recommendations. The duration of therapy correlates with infection severity. Antibiotics should be continued until the infection has resolved, but not necessarily until the ulcer has healed. Milder infections generally require 7 to 14 days of therapy; more severe infections may necessitate treatment durations of 2 to 3 weeks, or longer with bone involvement. Patients with osteomyelitis may require weeks to months of antibiotic therapy depending on whether the infected and necrotic bone is surgically debrided or amputated.[31,34]

INFECTED BITE WOUNDS

EPIDEMIOLOGY AND ETIOLOGY

Approximately one in two Americans will be bitten by an animal at least once during their lifetimes.[36] Although most bite wound injuries are minor, some will require medical treatment and account for 1% of all emergency department visits.[37]

Dogs cause most animal bites, typically open lacerations and crush injuries.[36,38] Cat bites are the second most common animal bite, most often puncture wounds involving the hand. Because cat bites are deep and penetrating, the development of infection is more common.[36]

Human bites result in up to 3% of hand bites. There are two types of human bite injuries. Occlusal injuries are inflicted by actual biting, whereas clenched-fist injuries are sustained when a person's closed fist hits another's teeth. Of the two, clenched-fist injuries typically are more prone to infectious complications.[36,39]

KEY CONCEPT Bite wound infections generally are polymicrobial.[5] Both the normal flora of the biter's mouth and that of the bite recipient's skin can be implicated. The bacteriology of the cat and dog mouth is quite similar. *Pasteurella multocida*, a gram-negative aerobe, is one of the predominant pathogens. Viridans streptococci are the most frequently cultured bacteria from human bite wounds, although empiric treatment should also provide coverage for *Eikenella corrodens*.[5,36] Table 76–7 provides a comprehensive list of cat-, dog-, and human bite–wound pathogens.

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of infected bite wounds is presented in Table 76–7.

Complications of infected bite wounds include abscess, septic arthritis, tenosynovitis, and osteomyelitis. Bites to the hand are particularly complication prone.[36] Unfavorable scarring may also be a complication.[38]

TREATMENT

The goals of therapy for an infected bite wound are rapid and successful eradication of infection and prevention of related complications.

Table 76–7

Etiology and Presentation of Infected Bite Wounds

Bacterial Pathogens

- *Dog and cat: Pasteurella multocida, Staphylococci*, streptococci *Moraxella* spp., *Eikenella corrodens, Capnocytophaga canimorsus, Actinomyces, Fusobacterium, Prevotella,* and *Porphyromonas* spp.
- *Human:* Viridans streptococci, *Staphylococcus aureus, E. corrodens, Haemophilus influenzae,* and β-lactamase–producing anaerobic bacteria.

Signs and Symptoms

- The onset of infectious symptomatology is typically 12–24 hours after the bite.
- Pain at the wound site is common.
- Erythema, edema, and purulent or malodorous drainage at the wound site are manifestations of infected wounds. The patient may be febrile.
- Limited range of motion may be present, especially if the hand is bitten.

Laboratory Tests

- Leukocytosis may be present.
- The clinician should obtain anaerobic and aerobic wound cultures only if the wound appears clinically infected.

Imaging Studies

- Radiographs should be obtained if the bite is on the hand, could have damaged bone or joints, or if an embedded object or tooth fragment is suspected.

Data from Refs. [5,36].

Nonpharmacologic Treatment

Thorough irrigation with normal saline is the first step in the care of an infected bite wound. The wound should be elevated and immobilized. Surgical closure may be advocated, especially for facial wounds. Wounds that are infected or at higher risk of infection, such as those on the hand, should be left open to close by secondary intention to decrease the risk of complications.[36,37]

Pharmacologic Treatment

Most bite wounds require antibiotic therapy only when clinical infection is present. *However, prophylactic therapy is recommended for wounds at higher risk of infection and bites requiring surgical repair*.[37] Antibiotic prophylaxis should be considered in patients at high risk of infection because of immunocompromise, or those with specific wound types, such as puncture wounds or crush injuries with tissue damage.[36]

The most effective agent for the treatment (and prophylaxis) of human and animal bite–wound infections is amoxicillin–clavulanate. Alternatives include second-generation cephalosporins, such as cefuroxime, plus coverage for anaerobes, such as clindamycin or metronidazole. Moxifloxacin, doxycycline, or a carbapenem may also be used. The duration of prophylaxis and treatment are generally 3 to 5 days.[5] Consider rabies prophylaxis as appropriate, based on recommendations from the Centers for Disease Control and local health department. Depending on the immunization status of the bite-wound victim, prophylaxis for tetanus may also be warranted.[36,39]

If the wound is associated with significant cellulitis and edema, systemic signs of infection, or possible joint or bone involvement, hospitalization and IV antibiotics (typically ampicillin–sulbactam 3 g IV every 6 hours) should be initiated. Bone and joint infections will require longer durations of therapy of up to 6 weeks.[5,39]

OUTCOME EVALUATION

Education of the patient, caregivers, and household members is important to limit further spread of infection and is a key component in ABSSSI case management. Table 76–8 lists several key prevention messages for patients with ABSSSIs.

Patients receiving antibiotic therapy for ABSSSIs require monitoring for efficacy and safety. Efficacy typically is manifested by reductions in temperature, white blood cell count, erythema, edema, and pain. Initially, signs and symptoms of infection may worsen owing to toxin release from certain organisms (ie, GAS); however, they should begin to resolve within 48 to 72 hours of treatment initiation. If no response or worsening infection is noted after the first 3 days of antibiotics, reevaluate the patient.[5] Lack of response may be due to a noninfectious or nonbacterial diagnosis, a pathogen not covered by or resistant to current antibiotic therapy, poor patient adherence, drug or disease interactions causing decreased antibiotic absorption or increased clearance, immunodeficiency, or the need for surgical intervention. To ensure the safety of the regimen, dose antibiotics according to renal and hepatic function as appropriate, and monitor for or minimize adverse drug reactions, allergic reactions, and drug interactions.

Table 76–8

Prevention Education for Patients with ABSSSIs

1. Draining wounds should be covered with clean, dry bandages.
2. Hands should be cleaned regularly with soap and water (or with alcohol-based hand gel if not visibly soiled) and immediately after touching infected skin or any item directly contacting a draining wound.
3. General hygiene should be maintained with regular bathing.
4. Items that may become contaminated with wound drainage or that directly touch the skin should not be shared.
5. Wash and dry thoroughly any clothing that has come in contact with wound drainage after each use.
6. If the wound is unable to be covered with a clean, dry bandage at all times, avoid activities with skin-to-skin contact until the wound is healed.
7. Equipment and environmental surfaces with bare skin contact should be cleaned with *Staphylococcus aureus*–active detergents or disinfectants.

From Gorwitz RF, Jernigan DB, Powers JH, et al. Strategies for clinical management of MRSA in the community: Summary of an experts' meeting convened by the Centers for Disease Control and Prevention [online]. 2006. Patient Care Process

Collect Information:

- Review the medical history and physical assessment findings.
- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Based on physical examination and review of systems, determine whether the patient is experiencing signs or symptoms of an ABSSSI, and if so, its severity.
- Based on the history and presentation, determine the most likely causative microorganism of the patient's infection to select treatment.
- Document current temperature, blood pressure, and heart rate.
- Review relevant laboratory tests (eg, complete blood count, renal function, basic metabolic profile, and culture and sensitivity report)
- Identify any significant adverse drug effects or interactions with current drug therapy.

Develop a Care Plan:

- Determine the most appropriate nonpharmacologic or pharmacologic treatment option(s) for the patient's infection based on presentation and history.
- Select the most appropriate antibiotic therapy that is likely to be effective and safe.
- Choose medications, doses, routes, and treatment durations that are optimal for the patient and will result in the resolution of infection. In pediatric patients especially, consider method and ease of administration, and palatability and tolerability of oral formulations.

Implement the Care Plan:

- Educate the patient about their drug therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about skin and skin structure infection and its management.
- Discuss importance of medication adherence to improve resolution of infection and reduce antimicrobial resistance.
- Determine whether the patient has insurance coverage or recommended agents are included on the institution's formulary.
- Abide by antimicrobial stewardship practices at the institution.

Follow-up: Monitor and Evaluate:

- Follow up at an appropriate interval to ensure resolution of infection.
- Review physical exam, vital signs, and lab tests to assess changes in clinical status and resolution of infection.
- Narrow antibiotic coverage when possible with the use of culture and sensitivity data.
- Reinforce proper infection prevention strategies.

Abbreviations Introduced in This Chapter

ABSSSI	Acute bacterial skin and skin structure infection
CA-MRSA	Community-acquired methicillin-resistant *S. aureus*
GAS	Group A *Streptococcus* (also known as *Streptococcus pyogenes*, one of the β-hemolytic streptococci)
GERD	Gastroesophageal reflux disease
HA-MRSA	Healthcare-associated methicillin-resistant *S. aureus*
IVIG	Intravenous immunoglobulin
MIC	Minimum inhibitory concentration
MRI	Magnetic resonance imaging
MRSA	Methicillin-resistant *S. aureus*
MSSA	Methicillin-sensitive *S. aureus*
NF	Necrotizing fasciitis
SIRS	Systemic inflammatory response syndrome
SSSI	Skin and skin structure infection
VISA	Vancomycin-intermediate *S. aureus*
VRE	Vancomycin-resistant enterococci
VRSA	Vancomycin-resistant *S. aureus*

Osteomyelitis

Jessica E. Burchette and David B. Cluck

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. List common risk factors for osteomyelitis.
2. Discuss the pathophysiology of osteomyelitis.
3. Compare and contrast the classic signs and symptoms of acute and chronic osteomyelitis.
4. Evaluate microbiology culture data and other laboratory tests and imaging studies utilized for diagnosis of osteomyelitis.
5. List the most common pathogens isolated in acute and chronic osteomyelitis.
6. Develop a treatment plan for osteomyelitis.
7. Recommend parameters to monitor antimicrobial therapy for effectiveness and toxicity.
8. Describe how principles of antimicrobial stewardship can be applied to the management of osteomyelitis.
9. Educate patients regarding lifestyle modifications that may impact disease outcomes.

INTRODUCTION

KEY CONCEPT Osteomyelitis is an infection of the bone that may be either an acute or chronic process. The inflammatory response associated with acute osteomyelitis can lead to bone necrosis and subsequent chronic infection.[1] Bacterial pathogens, such as *Staphylococcus aureus*, are most commonly responsible for both acute and chronic infections.[1-8] Diagnosis and treatment present significant challenges to clinicians due to the complex nature of osteomyelitis.[1,2] Medical management is considered the cornerstone of treatment for acute infections; however, surgical intervention in addition to antimicrobial therapy is necessary to achieve cure for chronic infections.[1,2]

KEY CONCEPT Osteomyelitis is most often classified by duration of disease and route of infection.[1,2,9]

Two major osteomyelitis classification schemes exist. The Cierny–Mader classification focuses on the affected portion of bone, physiologic status of the patient, and factors impacting local vascularity.[1] In contrast, the Waldvogel classification scheme categorizes disease based on route of infection (**hematogenous** or **contiguous**) and duration of disease (acute versus chronic).[9] Using this classification scheme, osteomyelitis secondary to a contiguous focus can be further subdivided into infections with or without vascular insufficiency. Typical bone involvement in osteomyelitis depends on the route of infection.

- Hematogenous: long bones (femur, tibia) in children and vertebra in the elderly[2–5,10]
- Contiguous with vascular insufficiency: lower extremities[2,11,12]
- Contiguous without vascular insufficiency: bones affected by trauma, surgery, or adjacent soft-tissue infection[1,5]

A single pathogen is most often isolated in hematogenous osteomyelitis, whereas multiple organisms are often isolated in contiguous infections.[7,10,11,13]

While there are no validated definitions delineating acute versus chronic infection,[1,9,10] acute infection is often defined as the first episode or onset of symptoms within 2 weeks.[2,9-11] In comparison, chronic osteomyelitis is generally defined as disease relapse or symptoms persisting beyond 2 months.[2,9] Because there is no abrupt temporal demarcation, but rather a gradual shift from acute to chronic infection, many describe chronic osteomyelitis as the presence of necrotic bone.[1,2,10,11]

EPIDEMIOLOGY AND ETIOLOGY

The most common origin of osteomyelitis is dependent on the age of the patient. Children are more likely to suffer from hematogenous disease while adults are more likely to develop osteomyelitis due to contiguous spread.[1-4,6] However, hematogenous osteomyelitis can also be seen in older adults and in patients with a history of intravenous (IV) drug abuse, with the spine (vertebral osteomyelitis) being the most common site of infection.[1,2,5]

KEY CONCEPT *S. aureus* is the predominant pathogen seen in all types of osteomyelitis, with methicillin-resistant *S. aureus* (MRSA) being increasingly reported.[1-4,6,10] Patient-specific risk factors have the greatest impact on the potential pathogens including the following:

- Uncontrolled diabetes and/or peripheral vascular disease (polymicrobial including MRSA, Enterobacterales, and *Pseudomonas aeruginosa*).[11,14]
- Sickle cell disease (*Salmonella* spp.).[1,2,7]
- Individuals with prosthetic implants (coagulase-negative staphylococci).[7]
- Neonates (*Escherichia coli* or group B streptococci).[2]
- Patients with pressure sores (polymicrobial).[2,7]

Regardless of patient-specific risk factors all patients with deep or extensive wounds, particularly those that are nonhealing should be evaluated for underlying osteomyelitis.[11,14]

PATHOPHYSIOLOGY

Both microbial and patient-specific factors are important determinants in the development of osteomyelitis.[1] Healthy bone tissue is normally resistant to infection but may become susceptible under certain conditions.[1,2] Bone can become infected: (a) via the presence of bacteria in the bloodstream (hematogenous), (b) by direct inoculation from trauma or surgery, and (c) by spread from an adjacent site (eg, soft-tissue infection) (contiguous).[1] The latter is particularly problematic in patients with implantable devices (eg, hip replacement), vascular insufficiency, and chronic skin ulcers.[1,11]

Staphylococcus species possess bacterial adhesins, which promote their attachment to tissues and prosthetic material.[1] Microbial adherence to bone elicits an inflammatory response.[1] The subsequent release of leukocytes and cytokines leads to local edema and **ischemia** facilitating bone necrosis.[1] Pieces of dead bone may become separated, forming **sequestra**.[1] The presence of sequestra is often indicative of chronic disease. These areas typically cannot be penetrated by antimicrobials or phagocytic cells due to poor blood supply and, thus, require surgical intervention to eradicate the bacterial **nidus**.[1,11]

CLINICAL PRESENTATION AND DIAGNOSIS

General

The clinical presentations of osteomyelitis may vary depending on route and duration of infection, as well as patient-specific factors such as infection site, age, and comorbidities.[1-4,7,11,14]

KEY CONCEPT Bone biopsy is the gold standard for confirmatory diagnosis of osteomyelitis. A bone biopsy allows for isolation of microorganism(s) from culture in addition to verifying the presence of inflammatory cells and osteonecrosis on histologic exam.[1,2,11-14] Due to the invasive nature of the bone biopsy, the diagnosis of osteomyelitis is often based on clinical findings, laboratory tests, and imaging studies.[1,12,13]

KEY CONCEPT Typical signs and symptoms of osteomyelitis include local pain and tenderness over the affected bone, as well as inflammation, erythema, edema, and decreased range of motion.[1,3,4,6,9] Patients with acute hematogenous osteomyelitis may also present with systemic symptoms such as fever, chills, and/or malaise.[1,3,4,9] A cardinal sign of chronic osteomyelitis is the formation of a sinus tract (a channel from the infected site to the skin) with purulent drainage.[1]

Laboratory Tests

Though no single noninvasive laboratory test is currently available for the diagnosis of osteomyelitis, several nonspecific tests are commonly used to aid in the diagnosis and to monitor response to therapy.

Nonspecific inflammatory markers for infection include:[1,2,4-6]

- White blood cell (WBC) count
- Erythrocyte sedimentation rate (ESR)
- C-reactive protein (CRP)
- Procalcitonin

WBC, ESR, and CRP are often elevated but may also be within normal limits. An elevated WBC is mostly seen in patients with acute osteomyelitis.[1,3,6,9] CRP rises faster than ESR during early stages of infection and also returns to normal levels more quickly than ESR. This makes CRP a more useful tool for both diagnosis and monitoring of therapeutic response.[4-6] Similar to CRP, procalcitonin may be useful for both diagnosis and monitoring of therapeutic response; however, it is often more expensive and may not be as readily available.[4]

Microbiologic Evaluation

Isolation of a causative pathogen from bone biopsy samples is essential for definitive antimicrobial therapy.[1-3,5,7,11,12] It is imperative cultures are obtained prior to initiation of antimicrobial therapy. If bone biopsy cannot be performed, quality specimens (eg, two consecutive samples with bone contact [deep samples] in patients with contiguous osteomyelitis[12,15] or blood cultures in patients with acute hematogenous osteomyelitis)[1,3,5] may assist in pathogen identification. Superficial swabs often represent colonization rather than infecting organism(s) and, thus, have little value in selecting therapy.[1,7,12,14]

Imaging Studies

Various imaging studies are used to assist in the diagnosis of osteomyelitis.[1,3,12,14,16,17]

- Magnetic resonance imaging (MRI) is considered the gold standard imaging modality for diagnosing of osteomyelitis.[1,3,4,11,13,14,16,17] Advantages include early detection (3–5 days after onset of symptoms), no radiation exposure, and high resolution.[1,6,16,17] Disadvantages include expense, inconvenience to patients (long examination time), movement artifacts, and the limitations to scanning patients with pacemakers and other implantable metal devices.[3,17]
- Computed tomography (CT) scans have high resolution and reproducibility.[17] CT scans have reduced sensitivity compared to MRI and should not be routinely used to diagnose osteomyelitis.[1,5,16] Advantages are that it is useful for the identification of sequestra and is less expensive than MRI.[3,16,17] Disadvantages include patient exposure to radiation and inability to use contrast medium to enhance images in patients with impaired renal function or previous allergic reactions.[3,4,17]
- Plain film radiographs (X-rays) are the initial imaging study of choice for skeletal infections.[1,5,6,12,16] Although changes in soft tissue may appear within 3 days of infection, bone lesions may not be visible for 10 to 21 days.[1,4,6,11,12,16] Advantages of radiographs are accessibility, cost, low radiation exposure, and they are easily repeatable.[5,16] A disadvantage is the inability to detect early bone infections.[1,3,4,6,11,16]
- Radionuclide imaging is also used for the early diagnosis of bone infections.[16] The most widely used nuclear medicine test is the three-phase bone scan.[16,17] An advantage is early detection within 24 to 48 hours after onset of symptoms.[5,6,16] Disadvantages include low specificity (increased risk of false positives) in patients with recent trauma, surgery, orthopedic prosthesis, diabetes, and ischemia, and high radiation dose required.[1,16] Using a labeled WBC scan in combination with the three-phase bone scan can increase sensitivity and specificity.[14,16]

TREATMENT

KEY CONCEPT The treatment goals for osteomyelitis are to eradicate the infection and prevent recurrence.[6-8,14,18]

General Approach to Treatment

KEY CONCEPT Antimicrobial therapy alone is the mainstay of treatment for acute osteomyelitis.[3-5,7] In comparison, treatment for chronic osteomyelitis typically requires a combination of antimicrobial therapy and surgical intervention.[7,11,14] If the patient is

Patient Encounter Part 1

A 55-year-old man presents to the emergency department complaining of pain and erythema in his left lower leg. On physical examination, the area is noticeably red and swollen (erythematous and inflamed). After reviewing his chart, you discover that he was recently discharged from the hospital approximately 3 weeks ago following a diagnosis of postsurgical osteomyelitis. During admission he underwent debridement and irrigation followed by IV daptomycin and wound VAC placement. He was discharged home with daptomycin to complete 8 weeks of therapy; however, he lost insurance coverage and only completed approximately 2 weeks of therapy in total.

What information is suggestive of osteomyelitis?

What risk factors, if any, does he have for osteomyelitis?

not a candidate for surgical intervention, prolonged antimicrobial therapy is generally necessary.[11-14]

▶ *Nonpharmacologic Therapy*

In addition to medical and surgical management, nonpharmacologic interventions for health promotion such as smoking cessation, weight-control, and good nutrition should be emphasized to the patient. Additionally, patients with diabetes should be counseled regarding the importance of frequent blood glucose monitoring and control, routine care and self-examination of lower extremities, and aggressive wound care.[14] Patients with chronic immobility should be counseled on skin care and techniques to prevent the development of pressure ulcers.[7]

▶ *Pharmacologic Therapy*

KEY CONCEPT Empiric antimicrobial therapy should target common pathogen(s) based on patient-specific risk factors and route of infection.[6] Empiric antimicrobial coverage against *S. aureus*, including MRSA, should be considered for all classifications of osteomyelitis.[1,2,6,7,19,20] In addition to MRSA coverage, patients with contiguous osteomyelitis with vascular insufficiency (eg, diabetic) should also receive empiric coverage for Enterobacterales, *P. aeruginosa*, and anaerobes.[11,14] Specific recommendations may vary based on factors such as patient allergies, potential for harboring resistant organisms, institution formulary, and cost considerations.[2,3,11]

Antimicrobial therapy should be guided by culture and susceptibility data of appropriately collected specimens when available (Table 77–1).[4,6,11,14] If MRSA is isolated, vancomycin is considered first-line therapy with an AUC/MIC target between 400 and 600 mg h/L.[22] However, if the minimum inhibitory concentration is greater than 2 mcg/mL (2 mg/L), alternative agents should be considered.[10,21,22] Alternative agents include daptomycin, linezolid, trimethoprim-sulfamethoxazole in combination with oral rifampin, or clindamycin.[21] Other MRSA active agents (tigecycline, telavancin, ceftaroline, dalbavancin, tedizolid, oritavancin) lack robust clinical data to support their routine use in osteomyelitis.[10,23] Clindamycin is commonly used in pediatric patients.[3,4,8,21] However, microbiology laboratories must screen with a disk diffusion test (D-test) for inducible resistance via the macrolide–lincosamide–streptogramin gene, as clindamycin failures have been associated with infections caused by isolates that are D-test positive.[3,24] For most institutions today, the D-test has been streamlined via automated susceptibility testing platforms. If methicillin-susceptible *S. aureus* (MSSA) is isolated and the patient has no β-lactam allergy, therapy should be changed to nafcillin/oxacillin or cefazolin.[1,2,5-7] Please refer to the Patient Assessment, Antimicrobial Selection and Stewardship chapter 72 for further discussion on general approach to antibiotic decision-making.

Patient Encounter Part 2

The medical team suspects incomplete resolution of osteomyelitis and ordered laboratory tests and imaging studies in addition to an orthopedic surgery service consult.

How would you classify the infection in this patient?

What laboratory test(s) should be ordered for this patient?

What imaging study(s) should be ordered for this patient?

In comparison to acute hematogenous osteomyelitis, chronic osteomyelitis is associated with higher failure rates, largely due to the presence of necrotic bone.[1,8,14,26] These patients typically require surgical intervention to remove the necrotic bone and tissue, and if applicable, to replace infected hardware.[7] Comorbidities such as vascular insufficiency can further contribute to poor treatment outcomes seen with chronic osteomyelitis.[1,7] Due to the high failure rates, treatment in this patient population may require prolonged courses of therapy, with the primary goal of preventing amputation of infected area(s).[1,11,14]

KEY CONCEPT Treatment is routinely initiated with IV antimicrobials in the inpatient or outpatient setting to optimize drug concentrations in bone.[7,14,16] Following initial IV therapy, a switch to oral antibiotics may be considered in patients with good clinical response, strict adherence, and reliable outpatient follow-up.[3,4,6,8,11,14,21] Moreover, findings from the Oral versus Intravenous Antibiotics for Bone and Joint Infection (OVIVA) study revealed patients may also be managed with oral therapy upfront after surgical intervention without adversely impacting outcomes.[25] Commonly used oral antimicrobials display high bioavailabilty including fluoroquinolones, doxycycline, clindamycin, linezolid, and trimethoprim-sulfamethoxazole.[1,6,7,19,21] Additionally, oral rifampin may be used in combination with another antibiotic in patients with osteomyelitis associated with prosthetic material or as part of step-down therapy for MRSA osteomyelitis in combination with trimethoprim-sulfamethoxazole.[1,7,11,21,26] For chronic osteomyelitis, some clinicians recommend placement of antibiotic impregnated beads or cement.[3,7,11,14] This enables antibiotics such as aminoglycosides and vancomycin to be delivered in high concentrations at the site of infection.[3,7]

KEY CONCEPT The duration of treatment is typically 4 to 8 weeks for acute and chronic osteomyelitis.[1-5,8,14,21] Shorter regimens may be considered for uncomplicated acute hematogenous infections due to *S. aureus* in children greater than 3 months of age.[4,6,8] Infectious Diseases Society of America (IDSA) MRSA guidelines recommend a minimum of 8 weeks for treatment of MRSA osteomyelitis in adults.[21] Suppressive therapy (> 3 months) may be necessary for certain populations such as patients with vascular insufficiency or patients with recalcitrant infections that do not respond to 4 to 8 weeks of therapy.[1,5,11,14,21]

Antimicrobial Stewardship Implications in the Management of Osteomyelitis

Stewardship programs have become increasingly common in an attempt to ensure appropriate antimicrobial use as well as to combat emerging resistance. Patients with osteomyelitis are typically subject to prolonged durations of therapy, and thus, much of the stewardship

Table 77–1

Pathogen-targeted Antimicrobial Therapy and Dosing Recommendations in Adults and Pediatrics

Microorganism	Antimicrobial Agent	Adult Dose	Pediatric Dose[a]
Staphylococcus aureus			
MRSA	Vancomycin[b]	15–20 mg/kg IV every 8–12 hours	15 mg/kg IV every 6 hours
	Daptomycin[b]	6–10 mg/kg IV every 24 hours	6–10 mg/kg IV every 24 hours
	Linezolid	600 mg IV/oral every 12 hours	10 mg/kg IV/oral every 8 hours(< 12 years old)
	Clindamycin[c]	600 mg IV every 8 hours 450 mg orally every 8 hours	10–13 mg/kg/dose IV/oral every 6–8 hours
	Trimethoprim-sulfamethoxazole[b] (+ rifampin[c] 600 mg oral daily)	3.5–4.0 mg/kg of trimethoprim component IV/oral every 8–12 hours (trimethoprim-sulfamethoxazole single strength tablet is 80 mg/400 mg; double strength tablet is 160 mg/800 mg)	–
	Doxycycline	100 mg IV/oral every 12 hours	–
MSSA	Nafcillin[d]/oxacillin[b]	1–2 g IV every 4–6 hours	100–200 mg/kg/day IV in divided doses every 4–6 hours
	Cefazolin[b]	1–2 g IV every 6–8 hours	50–100 mg/kg/day IV in divided doses every 6–8 hours
***Enterococcus* spp.**			
Ampicillin-susceptible	Ampicillin[b]	2 g IV every 4–6 hours	100–400 mg/kg/day IV in divided doses every 6 hours
Ampicillin-resistant	Vancomycin[b]	15–20 mg/kg IV every 8–12 hours	15 mg/kg IV every 6 hours
Vancomycin-resistant	Daptomycin[b]	6 mg/kg IV every 24 hours	–
	Linezolid	600 mg IV/oral every 12 hours	10 mg/kg IV/oral every 8 hours (< 12 years old)
***Streptococcus* spp.**	Penicillin G[b]	2–4 million units IV every 4–6 hours	250,000–400,000 units/kg/day IV in divided doses every 4–6 hours
	Ceftriaxone[d]	1–2 g IV every 24 hours	50–100 mg/kg/day IV in divided dose every 12–24 hours
Pseudomonas aeruginosa			
	Doripenem[b]	500 mg IV every 8 hours	–
	Imipenem/cilastatin[b]	500 mg IV every 6 hours	25 mg/kg IV every 6 hours
	Meropenem[b]	1 g IV every 8 hours	10–20 mg/kg IV every 8 hours
	Ceftazidime[b]	2 g IV every 8 hours	50 mg/kg IV every 8 hours
	Cefepime[b]	2 g IV every 12 hours	50 mg/kg IV every 8–12 hours
	Piperacillin/tazobactam[b]	4.5 g IV every 6 hours	100 mg/kg IV piperacillin component every 8 hours
	Ciprofloxacin[b,e]	400 mg IV every 8–12 hours; 750 mg oral every 12 hours	–
	Levofloxacin[b,e]	750 mg IV/oral every 24 hours	–
Enterobacterales (in addition to antipseudomonal agents listed above)	Ceftriaxone[d]	1–2 g IV every 24 hours	50–100 mg/kg/day IV in divided doses every 12–24 hours
	Cefotaxime[b,d]	1–2 g IV every 8 hours	50–200 mg/kg/day IV in divided doses every 6–8 hours
	Ertapenem[b]	1 g IV every 24 hours	–
	Moxifloxacin[c,e]	400 mg IV/oral every 24 hours	–
Anaerobes[f]	Clindamycin[c]	600–900 mg IV every 8 hours; 300–450 mg oral every 6–8 hours	25–40 mg/kg/day IV in divided doses every 6–8 hours
	Metronidazole[b,c]	500 mg IV/oral every 6–8 hours	30 mg/kg/day IV/oral in divided doses every 6–8 hours

[a] Refer to specialized pediatric reference for maximum neonatal and pediatric dosing recommendations.

[b] Dosage adjustment necessary in renal dysfunction.

[c] Dosage adjustment necessary in severe hepatic dysfunction.

[d] Dosage adjustment necessary in patients with concomitant renal and hepatic dysfunction.

[e] Fluoroquinolones: Not approved by the US FDA for use in children except for anthrax (ciprofloxacin, levofloxacin) and complicated UTI and pyelonephritis (ciprofloxacin).

[f] May consider β-lactam/β-lactamase inhibitor or carbapenem for broad-spectrum activity including anaerobes.

Data from Refs. [1,3,4,7,8,10,11,19,21-28].

focus should be on appropriate deescalation of empiric therapy and duration without sacrificing successful outcomes. Moreover, patients undergoing surgical amputation of the infected bone could receive abbreviated treatment courses of postsurgical antibiotics assuming clean margins are visualized by the surgical team.[14] As mentioned above, compliant patients with an identified organism may be switched to oral therapy, and those who require IV therapy should receive an agent with the narrowest spectrum. Stewardship opportunities may arise throughout the treatment course, and thus, opportunities to optimize patient care should be continually evaluated.

OUTCOME EVALUATION

Therapeutic success is measured by the extent to which the care plan (a) resolves signs and symptoms, (b) eradicates the microorganism(s), (c) prevents relapses, and (d) prevents complications such as amputation.[8,11,14] Patients should be evaluated for resolution of clinical signs and symptoms and normalization of laboratory tests (WBC, CRP, ESR, procalcitonin, and cultures).[3-6,8,10,14] Improvement in clinical manifestations may be seen within 2 to 4 days of initiation of IV antimicrobial therapy in patients with acute osteomyelitis.[4,8] A reduction in CRP should be seen within 1 week of therapy and should be monitored weekly throughout therapy for a continued downward trend.[3,4,6] ESR can also be monitored weekly, although normalization will be slower than for CRP.[3,6] Patients should also be closely observed with regard to therapeutic drug monitoring, antimicrobial tolerability, and toxicity[2] (Table 77–2). If poor response is noted, the

Patient Encounter Part 3: The Medical History, Physical Examination, and Diagnostic Tests

PMH: Morbid obesity, uncontrolled type 2 diabetes mellitus, obstructive sleep apnea, dyslipidemia, hypertension, history of DVT/PE, depression

SH: Tobacco smoker (one pack per day for 20 years), two to three cans of beer daily. Unemployed.

Allergies: Cefepime (leukopenia)

Meds: Warfarin 5 mg orally once daily; atorvastatin 40 mg orally at bedtime (held while receiving daptomycin); glargine 20 units subcutaneously at bedtime; metformin 1000 mg orally twice daily; hydrochlorthiazide 12.5 mg orally daily, metoprolol tartrate 100 mg orally twice daily; citalopram 20 mg orally daily

PE:

Gen: Moderate distress with exaggerated pain and tenderness in lower left leg

Skin: Erythema and inflammation

VS: BP 150/90 mm Hg, P 105 beats/min, RR 20 breaths/min, T 38.4°C (101.2°F), Ht 6′0″ (185.42 cm), Wt 142 kg (312.4 lb)

Labs: WBC 16.4×10^3/mm^3 (16.4×10^9/L), hemoglobin 13.0 g/dL (130 g/L; 8.07 mmol/L), hematocrit 37.0% (0.37), platelets 220×10^3/μL (220×10^9/L), BUN 23 mg/dL (8.2 mmol/L), serum creatinine (Scr) 1.3 mg/dL (115 μmol/L), total bilirubin 1.1 mg/dL (18.8 μmol/L), alkaline phosphatase 82 U/L (1.37 μkat/L), AST 28 U/L (0.47 μkat/L), ALT 13 U/L (0.22 μkat/L), albumin 3.7 g/dL (37 g/L), fasting blood glucose 210 mg/dL (11.6 mmol/L), ESR 110 mm/h, CRP 24 mg/dL (240 mg/L)

Microbiology: Previous intraoperative culture reveal methicillin-resistant *Staphylococcus aureus*, susceptible to daptomycin, vancomycin (MIC = 2 mcg/mL), linezolid, and trimethoprim/sulfamethoxazole.

Based on the information presented, create a care plan for this patient's osteomyelitis. Your plan should include (a) goals of therapy, (b) patient-specific detailed therapeutic plan, (c) nonpharmacologic interventions, and (d) follow-up plan to determine whether outcomes have been achieved.

Table 77–2

Monitoring Considerations for Select Antistaphylococcal Agents

Antimicrobial	Monitoring Considerations
Cefazolin	Monitor BMP and CBC once weekly.
Daptomycin	Muscle pain or weakness particularly of the distal extremities; monitor CPK weekly with more frequent monitoring in patients with renal insufficiency or receiving (or recent discontinuation) of HMG-CoA reductase inhibitors; consider temporarily discontinuing HMG-CoA reductase inhibitors while patient receiving daptomycin. Peripheral neuropathy: Monitor for neuropathy. Decreased efficacy was observed in patients with moderate baseline renal impairment.
Linezolid	Myelosuppression: Monitor CBC once weekly. MAO inhibitors; evaluate for potential drug–drug interactions. Linezolid should not be used concomitantly or within 2 weeks of medications that inhibit monoamine oxidases A or B. Serotonin syndrome; evaluate for potential drug–drug and drug–food interactions. Patients taking serotonergic antidepressants should receive linezolid only if no other therapies are available. Discontinue serotonergic antidepressants and monitor patients for signs and symptoms of both serotonin syndrome and antidepressant discontinuation. Peripheral and/or optic neuropathy has been reported with long-term therapy; perform routine neurologic and ophthalmic evaluations in these patients. Elevation of blood pressure in certain patients (eg, uncontrolled hypertension): monitor blood pressure. Hypoglycemia in patients with diabetes mellitus receiving insulin or oral hypoglycemic agents: monitor glucose.
Nafcillin/oxacillin	Monitor BMP, CBC, LFTs once weekly.
Vancomycin	An AUC/MIC target between 400 and 600 mg h/L is recommended for serious infections such as osteomyelitis. Renal dysfunction: monitor weekly renal function (BUN/SCr) and troughs in stable patients; more often in nonstable patients. Potential for additive renal toxicity if being coadministered with a nephrotoxic agent (eg, aminoglycoside, piperacillin-tazobactam).

BMP, basic metabolic panel; BUN, blood urea nitrogen; CBC, complete blood count; CPK, creatine phosphokinase; LFT, liver function tests; MAO, monoamine oxidase; SCr, serum creatinine.

Data from Refs. [1,7,11,19,21-27,29].

following should be evaluated: (a) patient adherence, (b) significant drug–drug or drug–food interactions, (c) appropriate dosage to achieve therapeutic concentrations, (d) development of antimicrobial resistance necessitating a change in the treatment regimen, (e) need for additional imaging studies, and (f) diagnostic reevaluation.[8,14] Treatment is considered successful if all clinical signs and symptoms are resolved and all laboratory tests have returned to normal following 4 to 8 weeks of appropriate treatment. Due to high rates of relapse, patients should have medical follow-up for at least 1 year following resolution of symptoms.[4] Patients should be evaluated at predefined follow-up intervals (3–6 to 12 months) for any clinical manifestations of recurring infection and continued normalization of laboratory tests.[8,11] Follow-up imaging studies at 1 to 2 years may be useful in some patients to confirm therapeutic success.

Patient Encounter Part 4

The patient received 2 weeks of IV daptomycin therapy following debridement but has not improved due to the interrupted treatment course. After being readmitted, he resumed IV daptomycin. Due to barriers with drug costs for this patient, the multidisciplinary medical team elects to complete therapy with oral antibiotic(s) at discharge.

What oral antimicrobial therapy would you recommend for this patient?

Evaluate the patient's medication profile for drug–drug interactions.

Counsel the patient regarding this drug therapy.

Patient Care Process

Collect Information:

- Review the medical history for osteomyelitis risk factors.
- Based on physical examination and review of systems, determine whether the patient is experiencing signs or symptoms of osteomyelitis.
- Review available imaging studies and laboratory tests, especially WBC, ESR, and CRP.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use.

Assess the Information:

- Review culture data for antimicrobial drug selection and stewardship.
- Evaluate drug allergies or intolerance, as well as drug–drug interactions that would impact antimicrobial selection.
- Assess available imaging studies and laboratory data to differentiate acute versus chronic disease.

Develop a Care Plan:

- Select an appropriate antimicrobial regimen, including drug, dose, and duration, given patient-specific information.
- Identify criteria for possible deescalation to oral therapy during treatment course.
- Establish monitoring parameters based on the antimicrobial regimen selected.

Implement the Care Plan:

- Provide patient education with regard to disease state and drug therapy. Stress the importance of adherence to the therapeutic regimen.

Follow-up: Monitor and Evaluate:

- Determine whether the antibiotic dosage regimen is optimal based on patient-specific factors and site of infection.
- Patients should be monitored for clinical and laboratory response, development of adverse drug reactions, potential drug–drug interactions, and therapeutic drug monitoring. Patients should also be closely monitored for adherence in the outpatient setting.

Abbreviations Introduced in This Chapter

ALT	Alanine aminotransferase
AST	Aspartate aminotransferase
BUN	Blood urea nitrogen
CBC	Complete blood count
CRP	C-reactive protein
CPK	Creatine phosphokinase
CT	Computed tomography
ESR	Erythrocyte sedimentation rate
IDSA	Infectious Diseases Society of America
IV	Intravenous
MAO	Monoamine oxidase
MRI	Magnetic resonance imaging
MRSA	Methicillin-resistant *Staphylococcus aureus*
MSSA	Methicillin-susceptible *Staphylococcus aureus*
Scr	Serum creatinine
WBC	White blood cell

78 Infective Endocarditis

Ronda L. Akins

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Differentiate the causes and development of infective endocarditis (IE).
2. Classify patient risk factors for potential causative organisms for IE.
3. Identify the clinical presentation and laboratory evaluation for IE.
4. Assess diagnostic criteria used to evaluate a patient suspected of having IE.
5. Discuss the most likely causative pathogens of IE, particularly in specific patient populations.
6. Develop appropriate pharmacologic treatment recommendations for patients with IE.
7. Describe oral step-down therapy options appropriate for specific types of IE and organisms.
8. Define appropriate patient populations requiring prophylactic treatment and differentiate appropriate drug regimens.
9. Devise a monitoring plan for patients with IE to determine treatment efficacy and discern any adverse effects.

INTRODUCTION

Infective endocarditis (IE) is a serious infection affecting the lining and valves of the heart. Although this disease is mostly associated with infection of the heart valves, whether native or prosthetic valves, septal defects or intravascular devices may also become involved in some cases. Bacteria are the primary cause of IE; however, fungi and atypical organisms may also be responsible pathogens.

Typically, IE is classified into two categories: acute or subacute. Differences between the two categories are based on the progression and severity of the disease. Acute disease is more aggressive, characterized by high fevers, leukocytosis, and systemic toxicity, with death occurring within a few days to weeks. This type of IE is often caused by more virulent organisms, particularly *Staphylococcus aureus*. Subacute disease is often caused by less virulent organisms, such as viridans group streptococci, producing a slower and more subtle presentation. It is characterized by nonspecific symptoms including fatigue, low-grade fever, and weight loss, with death occurring in several months.

Successful management of patients with IE is based on proper diagnosis, treatment with appropriate therapy based on organism identification and susceptibilities, and monitoring for complications, adverse events, or development of resistance. IE has varied clinical presentations; therefore, patients with this infection may be found in any medical subspecialty (ie, medicine, surgery, and critical care).

EPIDEMIOLOGY

In the United States, there are roughly 40,000 new cases annually, accounting for an incidence of approximately 3 to 15 cases per 100,000 persons-years.[1-4] Although the exact number of cases is often difficult to determine, owing to the diagnostic criteria and reporting methods for this disease, its incidence remains unchanged overall but is increasing in older patients, those with prosthetic valves, and infections due to *S. aureus*. IE is now considered the fourth leading cause of serious infectious diseases syndromes following sepsis, pneumonia, and intra-abdominal abscess.[5] Although IE occurs at any age, more than 50% of cases occur in patients older than 50 years.[1,3,4] IE in children continues to be uncommon and is mainly associated with underlying structural defects, surgical repair of the defects, or nosocomial catheter-related bacteremia.[1] With the increased use of mechanical valves, prosthetic-valve endocarditis (PVE) now accounts for approximately 16% to 35%.[6,7] Injection drug users are typically younger patients and also at an increased risk for IE, with 18 to 29 cases per 10,000 persons per year accounting for 5% to 15% of infection-related hospital admissions.[1,8,9] Additionally, others at high risk for IE include patients with any congenital or structural cardiac defects, including valvular disease, long-term hemodialysis, diabetes mellitus, poor oral hygiene, major dental treatment, previous endocarditis, hypertrophic cardiomyopathy, and mitral valve prolapse with regurgitation.[5,10]

Although almost any type of microorganism is capable of causing IE, the majority of cases are caused by Gram-positive bacteria. These consist primarily of streptococci, staphylococci, and enterococci. Consideration of Gram-negative, fungal, and other atypical organisms must be taken into account in select patient populations. In Table 78–1, approximate percentages are given for each organism based on the type of IE, including native valve (community-acquired vs healthcare-associated), prosthetic valve (grouped by months post surgery), and injection drug users. Additionally, other patient characteristics should be reviewed to assess risks of possible causative organisms and aid in empiric therapy choices (**see** Table 78–2).

Table 78–1

Etiologic Organisms of Infective Endocarditis

	Percentage of Cases							
	Native-Valve IE		PVE at Indicated Onset (Months) after Valve Surgery			IE in Injection Drug Users		
	Community-Acquired	HealthCare-Associated	< 2	2–12	> 12	Right-Sided	Left-Sided	Total
Streptococci[a]	40	13	1	9	31	5	15	12
Pneumococci	2	—	—	—	—	—	—	—
Enterococci[b]	9	16	8	12	11	2	24	9
Staphylococcus aureus	28	52[c]	22	12	18	77	23	57
CoNS	5	11	33	32	11	—	—	—
HACEK group	3	—	—	—	6	—	—	—
Gram-negative bacilli	1	1	13	3	6	5	13	7
Fungi (*Candida* spp.)	< 1	1	8	12	1	—	12	4
Polymicrobial/ miscellaneous	3	3	3	6	5	8	10	7
Diphtheroids	—	< 1	6	—	3	—	—	0.1
Culture-negative	9	3	5	6	8	3	3	3

[a] Includes viridans group streptococci; *S. gallolyticus* (formerly *S. bovis*); other nongroup A, groupable streptococci; and *Abiotrophia* and *Granulicatella* spp. (nutritionally variant streptococci).

[b] Primarily *E. faecalis* or nonspeciated isolates, occasionally *E. faecium*.

[c] Methicillin resistance is common among these *S. aureus* strains.

CoNS, coagulase-negative staphylococci; HACEK, *Haemophilus* spp. (primarily *H. paraphrophilus, H. parainfluenzae*, and *H. aphrophilus*), *Aggregatibacter actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens*, and *Kingella kingae*.

Modified from Karchmer AW. Infective endocarditis. In: Jameson J, Fauci A, Kasper D, Hauser S, Longo D, Loscalzo J, eds. Harrison's Principles of Internal Medicine, 20th ed. New York, NY: McGraw Hill; 2018: Chap. 123.

PATHOPHYSIOLOGY

KEY CONCEPT For IE to develop, the occurrence of several factors is required. Typically, there must be an alteration of the endothelial surfaces of the heart valves to allow for organism attachment and colonization. These alterations may be produced by an inflammatory process such as rheumatic heart disease or by injury from turbulent blood flow. Platelets and fibrin are then capable of depositing on the damaged valves, forming a nonbacterial thrombotic endocarditis (NBTE). At this point, bacteria, through

Patient Encounter Part 1

A 42-year-old man with a history of uncontrolled type II diabetes, injection drug use, recurrent cellulitis, osteomyelitis of the right foot, hypertension, and chronic kidney disease (CKD) stage 3 was brought to the emergency department (ED) after becoming very confused, dizzy, and complaining of numbness/weakness to the left arm. Upon arrival to the ED, the patient reported having recent "really bad" headaches, fever, shortness of breath, and abdominal pain. The patient denies any recent use of alcohol or tobacco but admits to illicit drug injection in the past couple of weeks. The ED physician started vancomycin (pharmacy to dose) and ceftriaxone 2 g IV every 12 hours.

Does the patient have any specific presenting signs or symptoms that would make you suspect IE?

What, if any, risk factors does the patient have for developing IE?

Based on presentation, which causative organism(s) should be considered to empirically treat?

Is there any other information you would like to know before deciding on an empirical treatment for this patient?

Table 78–2

Patient Characteristics for IE due to Select Organisms

Organism	Risk Factors for Specific IE Organisms
Staphylococcus aureus	Soft tissue infections (recurrent/chronic), injection drug use, prosthetic valves (early, late), indwelling devices, diabetes, burns, immunocompromised
Coagulase-negative staphylococci	Indwelling devices, injection drug use, prosthetic valves (early, late)
Viridans group streptococci	Dental health issues/procedures, prosthetic valves (late); GI/GU (*S. gallolyticus*)
Enterococci	GI/GU, prosthetic valves (late), immunocompromised
HACEK	Dental health issues/procedures
Gram-negatives	Injection drug use, prosthetic valves (early), burns, indwelling devices, GI/GU
Fungal	Indwelling devices, injection drug use, TPN (particularly long-term use), burns, prosthetic valves (early, late), immunocompromised (particularly transplant)

Data from Cresti A, Chiavarelli M, Scalese M, Nencioni C, Valentini S, Guerrini F, D'Aiello I, Picchi A, De Sensi F, Habib G. Epidemiological and mortality trends in infective endocarditis, a 17-year population-based prospective study. Cardiovasc Diagn Ther. 2017 Feb;7(1):27–35. doi: 10.21037/cdt.2016.08.09. PMID: 28164010; PMCID: PMC5253443.

hematogenous spread (ie, bacteremia), adhere to and colonize the nidus, forming a vegetation. Further deposits of platelets and fibrin cover the bacteria, providing a protective coating that allows for development of a suitable environment for continued organism and vegetation progression, often producing an organism density of 10^9 to 10^{10} colony-forming units (CFU) per gram.

Acquisition of PVE differs in early stages, where direct inoculation may occur during surgery rather than through hematogenous seeding. In addition, causative organisms in early PVE are typically nosocomial, with increased likelihood of being drug-resistant.[6] The prosthetic valve also has a greater propensity for organism colonization than native valves. However, in late PVE, the process of colonization and vegetation formation is similar to that of native-valve IE (NVE), as described earlier.[6,11] Differentiation of NVE versus PVE is important in determining empiric therapy as well as impacting the risk of disease complications (discussed later).

Typically, vegetations are located on the line along valve closure on the atrial surface of the atrioventricular valves (tricuspid and mitral) or on the ventricular surface of the semilunar valves (pulmonary and aortic) (see Figure 78–1A and C). The vegetations can vary significantly in size, ranging from millimeters to several centimeters and may be single or multiple masses. Often, destruction of underlying tissue occurs and may cause perforation of the valve leaflet or rupture of the chordae tendineae, interventricular septum, or papillary muscle. Valve ring abscesses may occur, resulting in fistulas penetrating into the myocardium or pericardial sac, particularly with staphylococcal endocarditis (see Figure 78–1B).

Embolic events are also common. Embolization occurs as portions of the friable vegetation break loose and enter the bloodstream. These infected pieces are called septic emboli. Pulmonary abscesses are commonly formed as a result of septic emboli from right-sided IE (tricuspid and pulmonary valves). However, left-sided IE (mitral and aortic valves) is more likely to have an embolus travel to any organ, especially kidneys, spleen, and brain. Along with emboli, immune complex deposition may occur in organ systems, causing extracardiac manifestations of the disease. This commonly occurs in the kidneys, producing abscesses, infarction, or glomerulonephritis. Immune complexes or emboli may also produce skin manifestations of the disease, as seen with petechiae, Osler nodes, and Janeway lesions, or within the eye (ie, Roth spots).

CLINICAL PRESENTATION AND DIAGNOSIS

To aid in the diagnosis, it is crucial to obtain a thorough account of the patient's medical history, present illness and signs/symptoms, given the clinical presentation for IE is quite variable and often nonspecific. **KEY CONCEPT** A fever is the most frequent and persistent symptom in patients but may be blunted with previous antibiotic use, congestive heart failure, chronic liver or renal

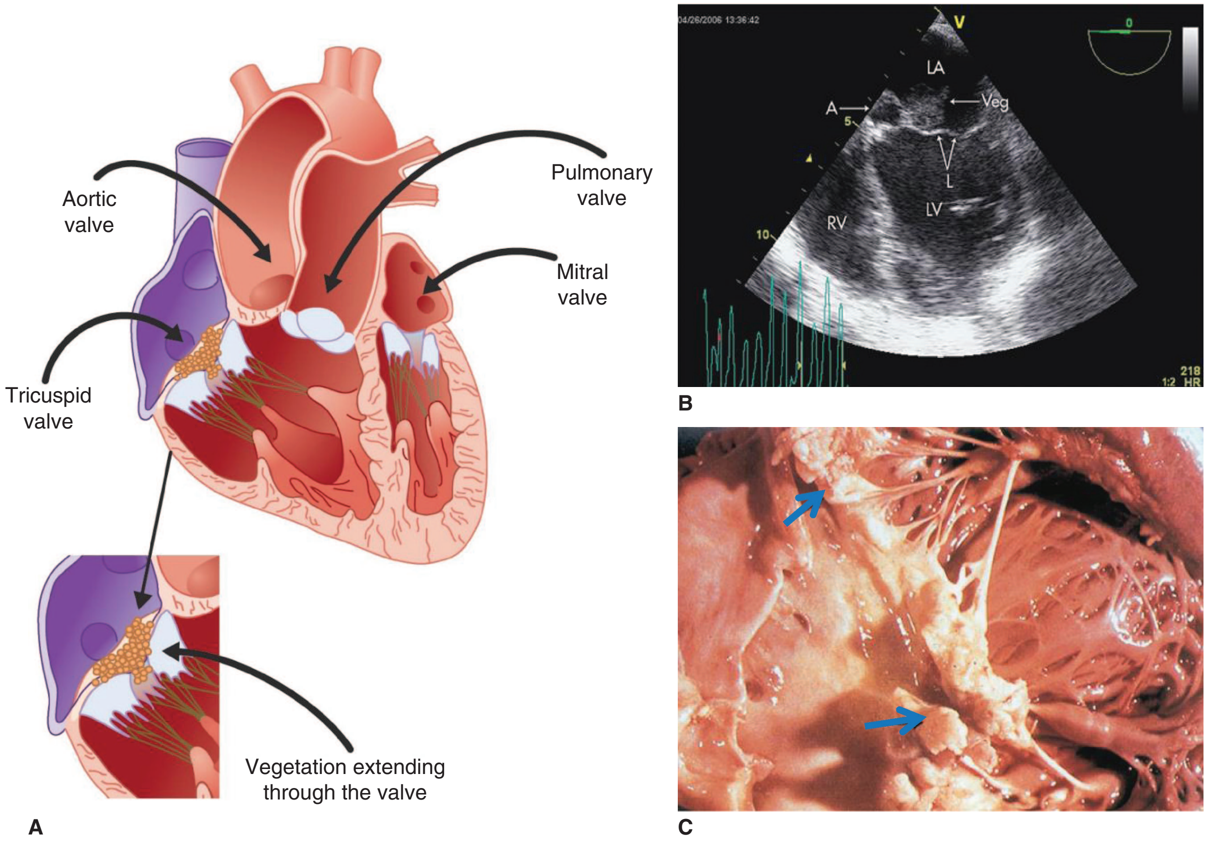

FIGURE 78–1. **A:** Diagram of heart and valves showing bacterial deposits and vegetation extending through the tricuspid valve. **B:** TEE of mitral heart valve infected with *Staphylococcus aureus* showing a large vegetation (Veg) with an adjacent echolucent abscess cavity (A), right ventricle (RV), left ventricle (LV), valve leaflets (L), and left atrium (LA). Table 78–3

Clinical Presentation and Diagnosis of IE

General

Typically nonspecific and variable sign or symptoms of infection

Symptoms

Complaints from patients may include

- Fever (≥ 100.4°F)
- Chills
- Night sweats
- Weakness
- Dyspnea
- Weight loss
- Myalgia or arthralgias

Signs

- Fever (most common sign of IE)
- New or changing/worsening heart murmur (occurs in 48% or 20%, respectively)
- Embolic phenomena (emboli affect the heart, lungs, abdomen, or extremities)
- Skin manifestations (ie, petechiae, splinter hemorrhages, Osler nodes, Janeway lesions)
- Splenomegaly
- Mycotic aneurysms
- Clubbing of extremities

Laboratory Tests

- Blood cultures (most important laboratory test)
- Hematologic tests for anemia (normochromic, normocytic)
- WBC count may be elevated in acute disease but could be normal in subacute IE
- Nonspecific findings such as thrombocytopenia, elevated erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP), and abnormal urinalysis (ie, proteinuria or microscopic hematuria)

Imaging Studies

- Transthoracic echocardiogram (TTE) and/or transesophageal echocardiogram (TEE); key imaging to identify presence of vegetations
- Computer tomography (CT) or magnetic resonance imaging (MRI); may be used to assess involvement of other organ systems (ie, lungs, kidneys, and brain)

failure, or infection caused by a less virulent organism (ie, subacute disease).[1,4] Other common signs and symptoms are listed in Table 78–3 with some discussed further in detail below.

Peripheral manifestations are classical signs that historically could be found in up to one-half of adult patients with IE. However, recently the prevalence of these findings has been decreasing, only occurring in a minority of adult patients and is rarely seen in children.[1,5]

- **Skin:** *Petechiae* are very small (usually < 3 mm), pinpoint, flat, red spots beneath the skin surface caused by microhemorrhaging. They occur in 20% to 40% of patients with chronic IE and are often found on the buccal mucosa, conjunctivae (Figure 78–2A), and extremities.[1,7] *Splinter hemorrhages* appear as small dark streaks beneath the fingernails or toenails and occur most commonly proximally with IE, typically as a result of local vasculitis or microemboli in about 5% to 15% of patients (Figure 78–2B).[7] *Osler nodes* are small (usually 2–15 mm), painful, tender, subcutaneous nodules located on the pads of the fingers and toes (Figure 78–2C) caused primarily by either septic emboli or vasculitis. These nodes are rare in acute disease (~3%–10%) but are also nonspecific for IE despite occurring in 10% to 25% in subacute patients.[1,7] *Janeway lesions* are small, painless, hemorrhagic macular plaques on the palms of the hands or soles of the feet due to septic emboli (in ~5%–10% of patients) and more commonly associated with acute *S. aureus* IE (Figure 78–2D).[1,7]
- **Extremities:** *Clubbing* of the finger tips typically occurs in long-standing subacute illness and is present in approximately 10% to 20% of patients (Figure 78–2E).[1]
- **Eye:** *Roth spots* occur rarely (< 5% of IE cases) and are oval-shaped retinal hemorrhages with a pale center near the optic disc (Figure 78–2F).[1]

Diagnostic Criteria

A definitive pathological diagnosis of IE consists of invasive testing such as a biopsy or culture directly from specimens of the endocardium. Instead, the clinical diagnosis of IE relies on patient's presentation as well as laboratory and echocardiographic results. To guide the clinical diagnosis of IE, major and minor criteria, known as the Duke criteria, have been established (Table 78–4A).[12] The number of major or minor criteria demonstrated by a specific patient leads to a classification of definite, possible, or rejected diagnosis of IE (Table 78–4B).

Laboratory and Imaging Studies

KEY CONCEPT Blood cultures are the essential laboratory test for the diagnosis and treatment of IE. Blood culture results are critical for determining the causative organism, thus aids in selection of the most appropriate therapy. Typically, patients with IE have a low-grade consistent bacteremia.[1] This low concentration of bacteria can impact detection in blood cultures. Therefore, three blood culture sets from different venipuncture sites should be drawn within 24 hours of initial evaluation to increase the likelihood of isolating any organism present. Approximately 90% of the first two cultures may yield a positive result.

KEY CONCEPT Another important tool aiding in the diagnosis of IE is the echocardiogram. This imaging tool is used to visualize the heart valves to assess the presence of vegetations. Two methods of the echocardiogram are used: the **transthoracic echocardiogram** (TTE) and the **transesophageal echocardiogram** (TEE). The TTE has been used since the 1970s; however, it is less sensitive (historically 40%–60%, newer imaging for native valves 82%–89%) than the TEE (90%–100%).[7] Despite the TEE being more sensitive, use of the TTE for patients with suspected NVE is usually sufficient for diagnosis.[13] However, some patient conditions may impact the resolution window from the body surface to the heart structures, lowering the sensitivity of a TTE, such as morbid obesity, previous thoracic surgery or chronic obstructive pulmonary disease. The TEE may be used as a secondary test for patients whose TTE was negative in the setting of high clinical suspicion of IE and is often preferred in patients with complicated disease, including left-sided IE, prosthetic valves, or perivalvular extension of the vegetation (**see** Figure 78–1B).[14,15]

In addition to echocardiograms, other imaging (computed tomography [CT] and magnet resonance imaging [MRI]), as well as newer modalities such as three-dimentional TEE, cardiac computed tomography angiography (CTA), multislice CT (MSCT), ^{18}F-fluorodeoxyglucose positron emission tomography (PET) CT (^{18}F-FDG-PET/CT), may also be employed for providing a more detailed assessment of the vegetation and surrounding structure, detecting complications secondary to septic emboli, and determining need for surgical intervention.[16,17]

Table 78–4

Modified Duke Criteria for Diagnosis of IE

4A. Definitions of Modified Duke Criteria

Major Criteria

- *Blood culture positive for IE:*
  - Typical microorganisms consistent with IE from two separate blood cultures:
    - Viridans streptococci, *S. bovis*, HACEK group, *S. aureus,* or community-acquired enterococci in the absence of a primary focus, or
  - Microorganisms consistent with IE from persistently positive blood cultures, defined as follows:
    - At least two positive cultures of blood samples drawn > 12 hours apart, or
    - All of three or a majority of four separate cultures of blood (with first and last sample drawn at least 1 hour apart)
  - Single positive blood culture for *C. burnetii* or antiphase I IgG antibody titer > 1:800
- *Evidence of endocardial involvement:*
  - Echocardiogram positive for IE (TEE recommended in patients with prosthetic valves, rated at least "possible IE" by clinical criteria, or complicated IE [paravalvular abscess]; TTE as first test in other patients), defined as follows:
    - Oscillating intracardiac mass on valve or supporting structures, in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation, or
    - Abscess, or
    - New partial dehiscence of prosthetic valve
    - New valvular regurgitation (worsening or changing of preexisting murmur not sufficient)

Minor Criteria

- Predisposition: predisposing heart condition or injection drug use
- Fever: temperature > 38°C (100.4°F)
- Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhages, and Janeway lesions
- Immunologic phenomena: glomerulonephritis, Osler nodes, Roth spots, and rheumatoid factor
- Microbiologic evidence: positive blood culture but does not meet a major criterion as noted above[a] or serologic evidence of active infection with organism consistent with IE

4B. Modified Duke Criteria to Diagnose IE

Definite IE

- *Pathologic criteria:*
  - (1) Microorganisms demonstrated by culture or histologic examination of a vegetation that has embolized, or an intracardiac abscess specimen, or
  - (2) Pathologic lesions; vegetation or intracardiac abscess confirmed by histologic examination showing active endocarditis
- *Clinical criteria*[b]:
  - (1) Two major criteria, or
  - (2) One major criterion and three minor criteria, or
  - (3) Five minor criteria

Possible IE

- (1) One major criterion and one minor criterion, or
- (2) Three minor criteria

Rejected

- (1) Firm alternate diagnosis explaining evidence of IE, or
- (2) Resolution of IE syndrome with antibiotic therapy for less than or equal to 4 days, or
- (3) No pathologic evidence of IE at surgery or autopsy, with antibiotic therapy for ≤ 4 days, or
- (4) Does not meet criteria for possible IE, as above

[a] Excludes single positive cultures for CNS and organisms that do not cause endocarditis.

[b] See above for definitions of major and minor criteria.

TEE, transesophageal echocardiography; TTE, transthoracic echocardiography.

Data from Li JS, Sexton DJ, Mick N, et al. Proposed modifications to the Duke criteria for the diagnosis of infective endocarditis. Clin Infect Dis. 2000; 30:633–638; by permission of Oxford University Press, 2000 by the Infectious Diseases Society of America.

ETIOLOGY

Gram-positive bacteria are the most common causative organisms in IE. Streptococci and staphylococci species account for the majority of cases at more than 80% to 90%.[1,18,19] Staphylococci are now considered the dominant causative organisms, with *S. aureus* being the most common (see Table 78–1).[1,5,17,19] Other Gram-positive, Gram-negative, atypical, and fungal organisms are less common, but still must be considered in certain patient populations (see Table 78–2).

▸ *Streptococci*

Streptococci causing IE are typically a group of species called viridans group streptococci. The most common of species in this group: *Streptococcus salivarius*, *Streptococcus mutans*, *Streptococcus mitis/oralis*, *Streptococcus anginosus*, and *Streptococcus sanguinis*. This group of bacteria is α-hemolytic and considered normal flora in the human mouth; thus, a common cause of oral infections but can result in bacteremia and subsequent development of IE after dental procedures. IE caused by these streptococci typically has a subacute clinical course. The current cure rate is often greater than 90% unless complications arise, which do occur in more than 30% of patients.[1,20]

Based on similarities of these organisms, most clinical microbiology laboratories do not differentiate all isolates to exact species. Viridans group streptococci are also a predominant pathogen of IE associated with mitral valve prolapse, NVE, and in children (particularly in those with congenital heart disease).[1,20,21] Another streptococcal species commonly associated with IE is *Streptococcus gallolyticus* (formerly *bovis*), classified as group D streptococci, which is frequently found in the gastrointestinal (GI) tract. Other streptococcal species (eg, *S. pneumoniae*, beta-hemolytic streptococci) are a rare cause of IE.

▶ *Staphylococci*

Staphylococcal endocarditis continues to increase in prevalence, causing 30% or more of all cases of IE, with the majority (80%–90%) being due to *S. aureus* (coagulase-positive staphylococci).[1-3,5,7] This increase in staphylococci has been primarily attributed to expanded use of venous catheters, more frequent valve replacement, and increased injection drug use.[1,5,7] Coagulase-negative staphylococci (CoNS) is also a cause of IE. However, these organisms frequently infect prosthetic valves over native valves or foreign material such as indwelling catheters; thus, staphylococci is the predominate causative pathogen in PVE.[1,6,22,23]

Patients with *S. aureus* bacteremia are at an increased risk of developing IE. *S. aureus* may infect "normal" heart valves (no prior detected valvular disease) in one-third of cases.[1,5] Therefore, it is imperative to assess these patients adequately for the presence of vegetations. Any heart valve may be affected; however, the mitral or aortic valve is most commonly involved, often resulting in extensive infection with a mortality rate of approximately 40% to 45%.[1,24] When managing *S. aureus* IE, one must consider whether the isolate displays methicillin resistance, the location of infection (right or left side), presence of prosthetic valves, and history of injection drug use. Despite significantly decreased activity of penicillinase-resistant penicillins (PRP; eg, oxacillin and nafcillin), most isolates remain susceptible to vancomycin. However, there is an increasing incidence of *S. aureus* with an elevated vancomycin MIC of 2 mcg/mL (2 mg/L) that may impact clinical outcome.[5,25,26] Additionally, strains with intermediate or fully resistant MICs to vancomycin have been rarely reported.[27-29]

The predominant coagulase-negative organism causing IE has been *S. epidermidis*. However, there has been an increase in isolation of another coagulase-negative species, *S. lugdunensis*.[30,31] Typically, coagulase-negative staphylococcal IE has a subacute course with numerous complications. Management (with or without surgical intervention) is usually successful. On the other hand, *S. lugdunensis* produces a more virulent infection, which is more comparable to that of *S. aureus* and, despite similar antibiotic susceptibilities to other CoNS, has a much higher mortality rate.[30]

▶ *Enterococci*

Enterococci are normal flora of the human GI tract and sometimes found in the anterior urethra. Affected patients are typically older men who have undergone genitourinary manipulations or younger women who have had obstetric procedures. Although enterococci are a less common cause of IE, there are two predominant species: *Enterococcus faecium* and *Enterococcus faecalis*. *E. faecalis* is the most common and more susceptible of the strains. However, enterococcal IE represents one of the most problematic Gram-positive bacterial infections to treat and cure. Enterococci, especially *E. faecium*, frequently display intrinsic and acquired resistance to multiple antibiotics, including penicillins, vancomycin, aminoglycosides, linezolid, and daptomycin.[32]

▶ *Gram-Negative Bacteria*

Gram-negative bacterial IE is much less common (~2%) but is typically much more difficult to treat than Gram-positive bacterial infections.[1,33] Fastidious organisms, such as the HACEK group, tend to predominate, causing approximately 3% of all NVE.[1,34,35] HACEK organisms consist of *Haemophilus* spp. (primarily *H. paraphrophilus, H. parainfluenzae*, and *H. aphrophilus*), *Aggregatibacter actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens*, and *Kingella kingae*. The clinical presentation of IE by these organisms is subacute, with approximately 50% of patients developing complications. These complications are primarily due to the presence of large, friable vegetations, and numerous emboli along with development of acute congestive heart failure often requiring valve replacement.[33,34,36] Traditionally, it was important to allow cultures sufficient incubation time (often 2–3 weeks) to isolate these organisms. Newer media and current automated incubation systems are now favored for recovery with timeframe similar to standard blood cultures (ie, 2–3 days). Despite improvements in culturing, these organisms may still present as culture-negative IE.

Other Gram-negative organisms, such as *Pseudomonas* spp., can cause IE, especially in injection drug users, healthcare exposure, and in patients with prosthetic valves. Additionally, IE may be caused by *Salmonella* spp., *Escherichia coli, Citrobacter* spp., *Klebsiella* spp., *Enterobacter* spp., *Serratia marcescens, Proteus* spp., and *Providencia* spp.[1,33]

Historically, Gram-negative IE typically had a poor prognosis with high mortality rates. Management, in addition to antimicrobial therapy, now often includes valve replacement in many patients. Therefore, as nondrug therapy advances to include cardiac surgery in more than half of patients, in-hospital mortality has improved to ~14% to 24%.[1,33]

▶ *Culture-Negative IE*

Negative blood cultures are reported in approximately 2% to 40% of IE cases, often resulting in delayed diagnosis and treatment.[1,7,19] Cultures that do not grow bacteria may be the result of previous antibiotic use, subacute right-sided disease, slow growth of fastidious organisms, nonbacterial endocarditis (eg, fungal or intracellular parasitic infections), non-IE, or improper collection of blood cultures. If nonbacterial or fastidious organisms are suspected, additional testing is essential.

▶ *Other Organisms*

Numerous other bacteria, including Gram-positive bacilli, unusual Gram-negative bacteria, atypical bacteria, and anaerobes, as well as spirochetes, are rare causes of IE.[1,5,37] Some of the more common organisms include *Legionella, Coxiella burnetii* (Q fever), and *Brucella*. These rare organisms occur primarily in at-risk patients such as those with prosthetic valves or injection drug users. A comprehensive discussion of these organisms is not feasible for this chapter; for further information, other references (particularly references 1, 5–7, 10, 20, 33, and 37 at the end of this chapter) should be examined. Identification of these organisms is difficult, and cure rates are low; thus, patients with these organisms should be managed by an infectious diseases specialist or endocarditis team.

▶ *Fungi*

Fungal endocarditis is quite uncommon but has significant mortality and typically affects patients with a history of cardiovascular surgery, pacemaker or prosthetic valves, total parenteral nutrition (TPN), prolonged courses of broad-spectrum antibiotics, long-term catheter placement, immunocompromised, or injection drug users.[7,38,39] Survival rates were historically poor with a current range of ~30% to 80%. Improvements in outcome have been reported owing to advances in diagnosis and treatment.[38,39] Poor prognosis has been attributed to large vegetations, propensity for organism invasion into the myocardium, extensive septic emboli, poor antifungal penetration into vegetations, and low toxic-to-therapeutic ratio and lack of cidal activity of certain antifungals.[38] The two most commonly associated organisms are *Candida* spp. and *Aspergillus* spp.

TREATMENT

General Approach to Treatment

Treatment of IE is complicated and difficult. Numerous factors involving vegetations influence the effectiveness of antimicrobial agents. The fibrin matrix of vegetations provides an environment where organisms are relatively free to replicate unimpeded, allowing the microbial density to reach very high concentrations (10^9–10^{10} CFU/g). Once organism density has reached this level, the majority of organisms are in a static growth phase. These factors hinder host defenses as well as the ability of antimicrobials to produce sufficient kill. This is often seen with β-lactams and glycopeptides as their effectiveness can be significantly diminished with increased bacterial inoculum and stationary growth phase of the bacteria. General recommendations encourage obtaining an infectious diseases/endocarditis team consult for all IE patients to aid in selection of empirical regimen, diagnosis, treatment duration, and management regardless of organism or disease severity.

KEY CONCEPT Selection of an appropriate antimicrobial agent must combine characteristics such as the ability to penetrate into the vegetation, the ability to achieve adequate drug concentrations, and the ability to be minimally affected by high bacterial inoculum to achieve adequate kill rates. **KEY CONCEPT** To accomplish this, parental, bactericidal antimicrobials are typically required to ensure optimal treatment, with an extended treatment course of 4 to 6 weeks (in most cases). Historically, parenteral therapy was recommended for the entire treatment duration. Patients would remain in the hospital minimally during the critical phase (initial 2 weeks) when complications are more frequent, then once clinically improved based on no systemic symptoms and negative follow-up blood cultures, therapy could be converted to daily administration of outpatient antimicrobial therapy (OPAT). However, OPAT may not be an option depending on factors such as lack of home healthcare access, transportation to outpatient infusion center or concern for central venous catheter in an injection drug user. Until recently, oral antibiotics were considered less reliable due to inconsistent GI absorption and potential subtherapeutic levels. However, a recent study, the POET trial (Partial Oral Treatment of Endocarditis) has lent support for transitioning to oral antibiotics as a safe and effective option for step-down therapy after receiving a minimum of 10 days of IV treatment and when giving a regimen consisting of at least two susceptible antibiotics in select patients with specific organisms and left-sided IE.[40] There are other studies in process to expand potential use of IV to oral antibiotics in IE. These include POET II (assessing shortened antibiotic therapy), RODEO-1 (left-sided IE due to susceptible staphylococci), and RODEO-2 (left-sided IE due to susceptible streptococci and enterococci).[41,42] However, based on current data, exploring use of early conversion to combination oral therapy with highly bioavailable agents may be an option in left-sided IE patients without significant cofounding factors to complete the treatment course. However, caution should be used as oral therapy is not suitable in many patients and consultation with the multidisciplinary endocarditis team is recommended to ensure selection of appropriate patient and treatment regimen/duration for this treatment option.

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Type II diabetes, hypertension, CKD stage 3, recurrent cellulitis, osteomyelitis of the right foot

Surgical History: None

FH: Mother has hypertension, CHF, dyslipidemia, and bipolar disorder, current age 68; father had a history of hypertension, ascites, cirrhosis, and end-stage liver disease, died at age 52.

SH: Currently living in his car. He admits to use of IV heroin but denied alcohol or tobacco usage.

Meds: Lisinopril 20 mg daily, insulin 70/30 50 units twice daily (previously on insulin glargine but unable to afford).

Allergies: Penicillin (rash) and trimethoprim/sulfamethoxazole (renal failure)

ROS: Ill appearing, weakness primarily to the left arm, shortness of breath, and generalized abdominal pain. Extremities with several mild hematomas and right foot with a chronic ulcer with some erythema and purulent drainage.

PE:

Weight: 188 lb **Height:** 5 ft 8 in.

VS: BP = 148/92 mm Hg, P = 98 beats/min, RR = 20 breaths/min, T = 39.6°C

Cardiovascular: Tachycardia, systolic murmur (not identified on previous admissions)

Abd: Soft, tender, guarded, nondistended; (+) bowel sounds

Labs: Within normal limits, except WBC = $22.8 \times 10^3/\mu L$ ($22.8 \times 10^9/L$), neutrophils = 86%, bands = 28%, SCr = 4.1 mg/dL (362.4 μmol/L), BUN = 62 mg/dL (22.1 mmol/L urea), ALT 168 U/L (2.8 μKat/L)

Given this additional information, what is your assessment of the patient's condition?

Do you have any other concerns based on the patient's presenting signs/symptoms?

What do you recommend for empiric treatment for this patient?

What other information or tests would be beneficial?

Nonpharmacologic Therapy

Surgery

Surgical intervention has become an integral therapy in combination with pharmacologic management of IE. Valve replacement is the predominant intervention and is used in almost one-half of all cases of IE.[1,37,43,44] Surgery is generally indicated if the patient has new or refractory congestive heart failure, significant valvular dysfunction, persistent infection despite antibiotics, more than one episode of serious emboli, large or mobile vegetations, mycotic aneurysm requiring resection, local complications (perivalvular or myocardial abscesses), PVE, or associated with a pathogen demonstrating higher antimicrobial resistance.[1,43,44] While timing of surgical intervention is still in question, patients with CHF or at high risk for emboli have improved outcomes with early surgery. Additionally, a patient's hemodynamic status (eg, blood pressure, heart rate, pulmonary artery pressure) should be assessed to determine when surgical intervention is warranted.[1] Despite appropriate medical management, a significant number of people who develop NVE require valve replacement surgery. Involvement of the aorta or development of IE complications is considered an indication for surgery in the majority of patients with PVE.[14,43,44] Based on the complexity of managing the needs (ie, medical, surgical, pharmacologic, and imaging) of IE patients, guidelines recommend utilizing a multidisciplinary group "endocarditis team." Subsequently, studies have now demonstrated positive outcomes including earlier surgical intervention, decreased length of hospital stay and antibiotic duration, and overall improved survival.[45,46]

Pharmacologic Therapy

Empirical Treatment

KEY CONCEPT The overall goal of therapy is to eradicate the infection and minimize/prevent any complications. Patients with suspected IE should be evaluated for risk factors that may provide some indication of the most likely causative organism. If no risk factors can be determined, empirical therapy should primarily cover Gram-positive bacterial organisms, specifically *S. aureus*, viridans group streptococci, and enterococci. Thus, vancomycin is a reasonable empiric therapy unless decreased local susceptibilities (mainly for enterococci) or patient concerns in which daptomycin would be more appropriate. If risk factors for other organisms are present, broaden coverage based on suspected pathogens. It is important to monitor the patient's response to therapy closely until cultures and susceptibilities are determined to ensure treatment is appropriately tailored to maximize patient outcome.

Organism Specific Treatment

The American Heart Association (AHA), as well as the European Society of Cardiology (ESC), has published guidelines for the management of IE, including specific treatment recommendations.[5,37] Both guidelines provide similar recommended treatment regimens (preferred antimicrobial agents and durations) for the most common organisms (streptococci, staphylococci, and enterococci) depending on whether the patient has NVE or PVE as listed in Tables 78–5 to 78–7. However, for more detailed information, refer to the complete guidelines.[5,37]

▶ *Streptococci*

The majority of viridans group streptococci and *S. gallolyticus* (*bovis*) remain very susceptible to penicillin. However, isolation of organisms with reduced penicillin susceptibilities is increasing; thus, antibiotic susceptibilities should be assessed to ensure the most appropriate treatment regimen. Owing to the similarities of these streptococci, most isolates have a penicillin MIC less than 0.12 mcg/mL (0.12 mg/L); therefore, penicillin G or ceftriaxone remain the preferred agents unless patients are unable to tolerate β-lactams or resistance is suspected. Typical length of treatment is 4 weeks and remains the most common duration. However, a shorter 2 week course may be employed for a patient with uncomplicated IE due to highly penicillin-susceptible strains with no extracardiac infection and creatinine clearance is greater than 20 mL/min/1.73 m^2 (0.19 mL/s/m^2). If the 2 week therapy is chosen, gentamicin should be added to the previous β-lactams for the entire course.

Patient Encounter, Part 3: Additional Laboratory and Diagnostic Tests

Preliminary Blood Cultures: Both sets (four out of four bottles) taken on admission in the emergency department are positive for Gram-positive cocci in clusters, coagulase-positive

Labs: CBC with differential and BMP obtained on day 4, all within normal limits excluding WBC = 21.2 × 10^3/μL (21.2 × 10^9/L), neutrophils = 82%, bands = 20%, SCr = 3.6 mg/dL (318.2 μmol/L), BUN = 78 mg/dL (27.9 mmol/L urea)

Echo: TTE revealed a large vegetation on the anterior mitral valve leaflet (2 × 2.5 cm) with moderate mitral valve regurgitation. The tricuspid valve was difficult to visualize but showed moderate regurgitation.

Given this additional information, would you make any changes in the assessment of your patient?

Would you adjust therapy at this time based on these new data?

Are you now able to determine treatment goals, including length of treatment?

What other information would you like to obtain?

When penicillin MICs for viridans group streptococci are greater than 0.12 mcg/mL (0.12 mg/L) but less than 0.5 mcg/mL (0.5 mg/L), antimicrobial duration should be increased to 4 weeks of penicillin G with gentamicin recommended during the first 2 weeks or ceftriaxone alone for 4 weeks. In patients with resistant strains of viridans group streptococci (MIC ≥ 0.5 mcg/mL [0.5 mg/L]), treatment should include antimicrobial agents utilized for enterococcal IE (precise agents determined by the susceptibility report) such as high-dose penicillin G or ceftriaxone combined with gentamicin. For any patient who is allergic or intolerant to β-lactams, vancomycin monotherapy is an alternative treatment option regardless of penicillin MIC.

Patients with PVE caused by viridans streptococci require treatment for 6 weeks with penicillin G or ceftriaxone in combination with gentamicin during the initial 2 weeks of therapy (if penicillin-susceptible), and with or without gentamicin over the entire 6 weeks (if less susceptible to penicillin, MIC > 0.12 mcg/mL [0.12 mg/L]). Vancomycin alone remains the primary alternative for β-lactam allergic patients.

Recommended therapies for viridans streptococci and *S. gallolyticus* (*bovis*) are summarized in Table 78–5.

▶ *Staphylococci*

It is important to determine (a) whether the isolate is methicillin-susceptible versus methicillin-resistant and (b) whether the

Table 78–5

Treatment Regimens for IE Caused by Viridans Group Streptococci and *S. gallolyticus (bovis)*

Regimen	Recommended Dose[a] and Route	Duration (weeks)	Comments
Native Valve IE caused by Highly Penicillin-Susceptible Strains, MIC ≤ 0.12 mcg/mL (≤ 0.12 mg/L)			
Penicillin G sodium[b]	2–3 million units IV every 4 hours	4	.
OR			
Ceftriaxone	2 g IV/IM every 24 hours	4	
Penicillin G sodium	2–3 million units IV every 4 hours	2	2-week regimen only recommended for uncomplicated NVE with creatinine clearance of > 20 mL/min/1.73 m^2 (0.19 mL/s/m^2); should not be used against *Abiotrophia, Granulicatella, or Gemella* spp. infection.
OR			
Ceftriaxone	2 g IV/IM every 24 hours	2	
PLUS			
Gentamicin[c]	3 mg/kg IV/IM once daily	2	If given as three divided doses, refer to Table 78–8 for synergistic dosing target concentrations; there are no optimal drug concentrations for single daily dosing.
OR			
Vancomycin	15 mg/kg every 12 hours	4	Should be used for patients unable to tolerate penicillin or ceftriaxone; refer to Table 78–8 for dosing target concentrations.
Native Valve IE caused by Relatively Penicillin-Resistant Strains, MIC > 0.12 to < 0.5 mcg/mL (> 0.12 to < 0.5 mg/L)			
Penicillin G sodium[b]	4 million units IV every 4 hours	4	If given as three divided doses, refer to Table 78–8 for synergistic dosing target concentrations; there are no optimal drug concentrations for single daily dosing.
PLUS			
Gentamicin[c]	3 mg/kg IV/IM once daily	2	
OR			
Ceftriaxone	2g IV/IM every 24 hours	4	If susceptible, ceftriaxone monotherapy may be considered.
Vancomycin	15 mg/kg every 12 hours	4	Should be used for patients unable to tolerate penicillin or ceftriaxone; refer to Table 78–8 for dosing target concentrations.
Prosthetic Valve or Other Prosthetic Material-related IE caused by Highly Penicillin-Susceptible Strains, MIC ≤ 0.12 mcg/mL (≤ 0.12 mg/L)			
Penicillin G sodium[b]	4 million units IV every 4 hours	6	
OR			
Ceftriaxone	2 g IV/IM every 24 hours	6	If given as three divided doses, refer to Table 78–8 for synergistic dosing target concentrations; there are no optimal drug concentrations for single daily dosing.
WITH OR WITHOUT			
Gentamicin[c,d]	3 mg/kg IV/IM once daily	2	
OR			
Vancomycin	15 mg/kg every 12 hours	6	Should be used for patients unable to tolerate penicillin or ceftriaxone; refer to Table 78–8 for dosing target concentrations.
Prosthetic Valve or Other Prosthetic Material-related IE caused by Relatively or Fully Penicillin-Resistant Strains, MIC > 0.12 mcg/mL (> 0.12 mg/L)			
Penicillin G sodium[b]	4 million units IV every 4 hours	6	
OR			
Ceftriaxone	2 g IV/IM every 24 hours	6	If given as three divided doses, refer to Table 78–8 for synergistic dosing target concentrations; there are no optimal drug concentrations for single daily dosing.
PLUS			
Gentamicin[c]	3 mg/kg IV/IM once daily	6	
OR			
Vancomycin	15 mg/kg every 12 hours	6	Should be used for patients unable to tolerate penicillin or ceftriaxone; refer to Table 78–8 for dosing target concentrations.

[a] Dose recommendations are based on patients with normal renal function. See Table 78–8 for additional dosing considerations.

[b] May give penicillin G sodium total daily dose as a continuous infusion. Ampicillin 2 g IV every 4 hours may be used as an alternative during shortage of penicillin.

[c] Avoid use of other potentially nephrotoxic drugs if receiving gentamicin therapy. Preferred given as a 3 mg/kg single dose, although may be administered in three divided doses.

[d] No benefit has shown combination therapy resulted in superior cure rates over monotherapy in PVE due to susceptible streptococci.

IM, intramuscular; IV, intravenous

Data from Refs. [1,5,6,37].

patient has a native versus prosthetic valve. For patients with NVE, methicillin-susceptible staphylococcal treatment should consist of a PRP or cefazolin, and for methicillin-resistant strains, therapy should consist of vancomycin or daptomycin (see Table 78–6). Duration for all therapies should be for 6 weeks. In patients with central nervous system (CNS) involvement (eg, brain abscess), use of PRP or vancomycin is recommended. If use of daptomycin is needed, consult with infectious diseases/endocarditis team is recommended to assist in optimal dosing.

For staphylococcal PVE, treatment length increases significantly, typically requiring a minimum of 6 weeks (see Table 78–6). For methicillin-sensitive staphylococci, a PRP should still be used, as well as vancomycin for methicillin-resistant staphylococci. Duration of therapy should be at least 6 weeks. However, with either regimen, addition of gentamicin (for synergy) for first 2 weeks and rifampin (to aid in preventing bacterial adherence to prosthetic devices given its ability to penetrate biofilms) for the entire length of treatment is recommended. Infectious diseases or

Table 78–6

Treatment Regimens for IE Caused by Staphylococci

Regimen	Recommended Dose[a] and Route	Duration (weeks)	Comments
Native Valve IE			
Oxacillin-Susceptible Strains			
Nafcillin or oxacillin	2 g IV every 4 hours	6	If unclear penicillin allergy, may perform skin testing.
Cefazolin	2 g IV every 8 hours	6	If anaphylactic to penicillin, recommend use of vancomycin instead of cefazolin.
Oxacillin-Resistant Strains			
Vancomycin	15 mg/kg every 12 hours	6	Refer to Table 78–8 for dosing target concentrations.
Daptomycin	≥ 8 mg/kg every 24 hours	6	
Prosthetic Valve IE			
Oxacillin-Susceptible Strains			
Nafcillin or oxacillin	2 g IV every 4 hours	≥ 6	Cefazolin may be used as an alternative to PRP.
PLUS			.
Rifampin	300 mg IV/PO every 8 hours	≥ 6	
PLUS			
Gentamicin	1 mg/kg IV/IM every 8 hours	2	Refer to Table 78–8 for synergistic dosing target concentrations.
Oxacillin-Resistant Strains			
Vancomycin	15 mg/kg every 12 hours	≥ 6	Refer to Table 78–8 for dosing target concentrations.
PLUS			
Rifampin	300 mg IV/PO every 8 hours	≥ 6	
PLUS			
Gentamicin	1 mg/kg IV/IM every 8 hours	2	Refer to Table 78–8 for synergistic dosing target concentrations.

[a] Dose recommendations are based on patients with normal renal function. See Table 78–8 for additional dosing considerations.

IM, intramuscular; IV, intravenous; PRP, penicillinase-resistant penicillin.

Data from Refs. [1,5,6,37].

Table 78–7

Treatment Regimens for IE Caused by Enterococci

Regimen	Recommended Dose[a] and Route	Duration (weeks)	Comments
Native Valve IE or PVE; Penicillin and Aminoglycoside[b] Susceptible; and Able to Tolerate β-lactam Therapy			
Ampicillin	2 g IV every 4 hours	4–6	NVE: if ≤ 3 months symptoms, 4-week therapy
OR			if > 3 months symptoms, 6-week therapy
Penicillin G sodium[c]	3–5 million units IV every 4 hours	4–6	PVE: 6-week therapy
PLUS			
Gentamicin	1 mg/kg IV/IM every 8 hours	4–6	
OR			
Dual *β-lactam*			Recommended for patients with impaired renal function (creatinine clearance < 50 mL/min/1.73 m^2 [0.48 mL/s/m^2]), or in patients who develop renal impairment or have toxicity secondary to gentamicin.
Ampicillin	2 g IV every 4 hours	6	
PLUS			
Ceftriaxone	2 g IV every 12 hours	6	
Native Valve IE or PVE; Penicillin Resistant; and Aminoglycoside Susceptible; or Unable to Tolerate β-lactams			
Vancomycin	15 mg/kg every 12 hours	6	If β-lactamase-producing strains and patient can tolerate a β-lactam antibiotic, ampicillin-sulbactam[d] plus gentamicin may be used.
PLUS			
Gentamicin	1 mg/kg IV/IM every 8 hours	6	
Native Valve IE or PVE; Penicillin, Aminoglycoside, and Vancomycin Resistant			
Daptomycin	10–12 mg/kg every 24 hours	> 6	
OR			
Linezolid	600 mg IV/PO every 12 hours	> 6	Bacteriostatic agent

[a] Dose recommendations are based on patients with normal renal function. See Table 78–8 for additional dosing considerations.

[b] For gentamicin-resistant strains, if streptomycin is susceptible, may substitute for gentamicin for each regimen listed (dose is 7.5 mg/kg IV or IM every 12 hours based on ideal body weight).

[c] May give penicillin G sodium total daily dose as a continuous infusion.

[d] Ampicillin-sulbactam dose is 3 g IV every 6 hours.

IM, intramuscular; IV, intravenous; PO, oral.

Data from Refs. [1,5,6,37].

endocarditis team consultation is recommended for all patients with *S. aureus* IE, irrespective of methicillin-susceptibility, due to an observed reduction in mortality associated with expert consultation in this patient population.[45,46]

Observed suboptimal outcomes in some cases of staphylococcal IE necessitates the expanded use of alternative therapies. Typically, standard therapy for MSSA is sufficient. However, for persistent MSSA bacteremia, combination β-lactams or use of alternative agents may be utilized. For MRSA, daptomycin is a reasonable alternative if the patient either has persistent bacteremia or the isolate has an elevated vancomycin MIC of 2 mcg/mL (2 mg/L), particularly if lack of clinical improvement noted. The approved daptomycin dosing for right-sided IE is 6 mg/kg/day (unless renal adjustments are necessary); however, guidelines recommend higher dosages of greater than or equal to 8 mg/kg.[5,25,37] Additionally, other antibiotics, such as ceftaroline, linezolid, telavancin, and long-acting lipoglycopeptides alone or in combination, have been used in patients with variable response rates.[32,47-50] These therapies often are reserved for patients who have been unresponsive to traditional therapy or for multidrug-resistant organisms, including those with reduced susceptibility to vancomycin.

▸ *Enterococci*

For enterococci, it is imperative to determine the specific species given significant differences in antibiotic susceptibility patterns between the two most common organisms (*E. faecalis* vs *E. faecium*). Historically, the mainstay of treatment for susceptible strains has been penicillin, ampicillin, or vancomycin, each combined with gentamicin for a total of 6 weeks. However, patients were often unable to tolerate or developed varying degrees of renal impairment (ie, toxicity). Therefore, the dual beta-lactam regimen, comprising ampicillin and ceftriaxone, is now commonly employed, particularly for *E. faecalis*.[5] As resistance develops to penicillin or ampicillin, vancomycin may provide adequate coverage. Once the isolate becomes resistant to vancomycin, daptomycin and linezolid are currently the most appropriate/viable treatment options. Refer to Table 78–7 for a summary of treatment regimens.

Treatment options for vancomycin-resistant enterococci (VRE) have not been well established. However, current recommendations for treating vancomycin-resistant enterococcal isolates include linezolid or daptomycin for a minimum of 6 weeks. The most likely species to develop vancomycin resistance is *E. faecium*, as *E. faecalis* infrequently develops multidrug resistance and ampicillin susceptibility is typically retained in this latter species. As per AHA IE guidelines, dosing for the recommended therapy is daptomycin 10 to 12 mg/kg/dose and linezolid 600 mg IV or orally every 12 hours. However, use of either agent has concerns. Linezolid is a bacteriostatic agent with potential for resistance development and/or increased likelihood of significant hematological side effects over a prolonged treatment course. Daptomycin is considered a bactericidal agent, but development of resistance is increasing; thus, dual therapy with β-lactams (eg, ampicillin or ceftaroline) has been shown to enhanced activity even for daptomycin nonsusceptible organisms. Synergistic combinations with gentamicin, rifampin, or tigecycline have also been utilized with variable results. Other potential agents include long-acting lipoglycopeptides (minimal data at this point) or quinupristin/dalfopristin (rarely used secondary to side effects and intrinsic resistance to *E. faecalis*).[48,50] Even with agents displaying susceptibility, combination therapy is often warranted; therefore, consultation with an infectious diseases specialist or endocarditis team is recommended if VRE is identified.

▸ *Gram-Negative Bacteria*

Identification of the exact pathogen is crucial in Gram-negative bacterial IE as treatment decisions depend on which organism is isolated. Therapy is usually targeted to the most susceptible antibiotics. Combination therapy is commonly used, usually with the addition of an aminoglycoside or fluoroquinolone. For example, *Pseudomonas* spp. are treated with an antipseudomonal β-lactam (eg, piperacillin/tazobactam, cefepime, meropenem) plus high-dose aminoglycoside (typically tobramycin 8 mg/kg/day).[1] However, exact dosing of antibiotics depends on the organism isolated. Length of treatment is usually a minimum of 6 to 8 weeks and often includes surgical intervention (ie, valve replacement surgery). Consultation with an infectious diseases specialist or endocarditis team is recommended.

▸ *HACEK Group*

The HACEK group bacteria are difficult to isolate, often leading to culture-negative IE. If one of these organisms is suspected, it is important to initiate appropriate empirical treatment. The preferred regimen is ceftriaxone (or another third- or fourth-generation cephalosporin), followed by ampicillin-sulbactam due to the increased occurrence of β-lactamase–producing strains. However, for patients who are intolerant of these treatments, fluoroquinolones may be used. The length of treatment for these organisms is typically 4 weeks (NVE) or 6 weeks (PVE).

▸ *Culture-Negative IE*

Treatment for culture-negative IE presents a significant dilemma. As outlined above, therapeutic regimens are usually guided by isolated organisms. When cultures fail to identify a specific organism, decisions regarding empiric treatment should cover the most common causative pathogens. Patient characteristics and risk factors aid in defining additional organisms requiring coverage.[5] Empiric regimens should also consider acute vs subacute presentation and NVE or PVE. The AHA recommends the following empiric regimens: vancomycin and cefepime (for NVE, acute presentation) plus rifampin and gentamicin (for early PVE, ≤ 1 year); vancomycin and ampicillin/sulbactam (for NVE, subacute presentation); or vancomycin plus ceftriaxone (for late PVE, > 1 year). If the patient is unresponsive to initial treatment, additional coverage for less common organisms becomes warranted. An infectious diseases specialist or endocarditis team should be consulted for the management of culture-negative IE.

▸ *Fungi*

Treatment of fungal IE is exceptionally difficult. There is a significant lack of evidence to identify the most appropriate therapy. Currently, amphotericin B is the most common treatment. However, valve replacement surgery is often considered a necessary adjunctive therapy in the majority of cases. Intravenous antifungal therapy requires high doses for a minimum of 6 weeks of treatment, often followed by life-long oral suppression therapy (ie, oral triazoles). Newer antifungals may be effective options, including echinocandins (eg, caspofungin) and voriconazole, depending on the organism and susceptibilities.[38]

Antimicrobial Dosing Considerations

The majority of antibiotic and antifungal agents used for the treatment of IE require dosing modifications based on renal or hepatic function. However, the most closely monitored are vancomycin and aminoglycosides. This is due in part because (a) therapeutic

Patient Encounter Part 4: Additional Laboratory

Susceptibility Report: *Staphylococcus aureus*

Drug	MIC (mg/L)	Interpretation
Ceftaroline	≤ 1	S
Clindamycin	≤ 0.25	S
Daptomycin	≤ 1	S
Erythromycin	> 8	R
Gentamicin	≤ 4	S
Linezolid	≤ 4	S
Oxacillin	≥ 4	R
Penicillin	≥ 8	R
Vancomycin	2	S
Tetracycline	8	I
Trimethoprim/ Sulfamethoxazole	≤ 0.5/9.5	S

Repeat blood cultures: Preliminary blood cultures from day 4—*Staphylococcus aureus*

Echo: TEE confirms large mitral valve vegetation (2.2 × 2.8 cm) and shows a 1.5 × 2 cm vegetation on the tricuspid valve

CT: Brain showed multiple low-density bilateral lesions of the temporal lobe, and right parietal lobe, suggestive of cerebral embolism. CT: Chest revealed multiple bilateral parenchymal nodular and wedge-shaped consolidations

VS Day 7: BP = 136/83 mm Hg, P = 85 beats/min, RR = 20 breaths/min, T = 38.9°C

Labs: CBC with differential and BMP obtained on day 7, all within normal limits excluding WBC = 19.7×10^3/μL (19.7×10^9/L), neutrophils = 78%, bands = 16%, SCr = 2.4 mg/dL (212.2 μmol/L), BUN 36 mg/dL (12.9 mmol/L urea)

Given this additional information, are there any changes in your assessment of the patient?

Do you need to adjust your treatment regimen based on these data?

What are your treatment goals, including nonpharmacologic therapy and length of treatment?

drug monitoring of serum concentrations is normally utilized to guide therapy, and (b) there is an increased likelihood of toxicity (ie, nephrotoxicity, ototoxicity) if the drug concentration is too high or adverse outcomes (ie, clinical failure or resistance development) if level is too low. Recently updated guidelines for vancomycin dosing for serious infections due to MRSA focused on utilization of area under the concentration–time curve (AUC)/MIC for the pharmacokinetic/pharmacodynamic (PK/PD) predictor of efficacy over use of trough concentrations.[26] This is particularly recommended for *S. aureus* isolates with an MIC of less than or equal to 1 mcg/mL (1 mg/L) as routine vancomycin dosing would obtain the recommended goal AUC/MIC of 400 to 600 based on assessment of vancomycin serum peak and trough concentrations. There are limited data on target AUC/MIC for *S. aureus* isolates with an MIC of 2 mcg/mL (2 mg/L) and use of alternative therapies may be considered, particularly if lack of clinical improvement is observed. Additionally, these vancomycin guidelines do not specify PK/PD parameters for streptococci or enterococci. The AHA specifies goal troughs of 10 to 15 and 10 to 20 mg/L (6.9-10.4 and 6.9-13.8 μmol/L). for streptococci and enterococci, respectively.[5] However, based on the complicated nature of IE, a goal trough of 15 to 20 mg/L (10.4-13.8 μmol/L) is typically employed. Other general dosing considerations are included in Table 78–8 for the most common drugs used in the treatment of IE. However, specific dosing adjustments for individual patients should be determined by referring to an appropriate drug dosing reference.

Prophylaxis

KEY CONCEPT Certain conditions have been associated more commonly with IE due to preexisting cardiac disease in the presence of a transient bacteremia. In an effort to prevent the development of IE, prophylactic treatment is generally considered appropriate for these at-risk patients. Although there are no well-controlled clinical studies of these recommendations, it is thought that if antibiotics are given just prior to a procedure, the number of bacteria may be decreased in the bloodstream and prevent the bacteria from adhering to the valves.

Cardiac conditions in which prophylaxis is reasonable include presence of prosthetic valves or material, prior IE, select forms of congenital heart disease, and cardiac transplant patients with cardiac valvulopathy (Table 78–9).[10] Although many patients have other cardiac dysfunction, only patients with these conditions are considered to be at a high risk of developing IE. No prophylaxis is advised in other patients.

Transient bacteremia may occur due to many types of dental and surgical procedures. However, the AHA guidelines significantly limit the types of procedures where prophylaxis is appropriate. Only dental procedures involving manipulation of gingival tissue or periapical region of teeth or perforation of the oral mucosa are considered to increase the likelihood that high-risk patients will develop IE.[10] Viridans group streptococci are the primary bacteria targeted for prophylaxis in this circumstance. On the other hand, prophylaxis should be given to patients undergoing GI or genitourinary (GU) surgeries that primarily targets enterococci.

The AHA guidelines include suggested antibiotic regimens for dental procedures for which prophylaxis is warranted.[10] Recommended regimens are summarized in Table 78–10. These guidelines recommend a single oral or intramuscular/intravenous dose initiated shortly before the procedure. A second prophylactic dose is not recommended. However, if an infection develops at the procedure site, additional antibiotics (ie, a therapeutic course) may be required.

Patient Encounter Part 5: Create a Care Plan

Based on this patient's information, create a care plan for the management of his IE. Be sure to include:

(a) A statement regarding treatment requirements and/or possible problems

(b) Goals of therapy

(c) A patient-specific plan, including preventive plans

(d) A follow-up plan to assess whether the goals have been met and to determine whether the patient experienced any adverse effects

Table 78–8

Dosage and Monitoring Considerations of Antibiotics for Treatment of IE[a]

Drug	Renal Adjustment	Hepatic Adjustment	Comments
Ampicillin	Required	None	Seizures most common AE if dosing not adjusted. Monitor for potential development of allergic interstitial nephritis (AIN).
Ampicillin/ Sulbactam	Required	None	Monitor for potential development of AIN.
Cefazolin	Required	None	Not recommended for IE with brain abscess due to insufficient penetration of blood–brain barrier (PRP preferred).
Ceftriaxone	If severe (see comment)	None	Do not exceed 2 g/day if patient has BOTH severe renal AND hepatic impairment
Daptomycin	Required	None	CPK should be monitored prior to and during therapy (at least weekly, and more frequently if increasing or on concomitant medications associated with muscle toxicity, particularly statins). Recommend to discontinue/switch therapy if patient symptomatic for myopathy when CPK is > 5 times upper limit of normal or if asymptomatic and CPK is > 10 times upper limit of normal.
Gentamicin	Required	None	Dosing should be based on ideal body weight; however, if significantly obese, use of adjusted body weight may be required to achieve target levels (listed below). Monitor therapeutic concentrations to guide dosage adjustments and target concentrations. Gentamicin: Only used as synergy (combination therapy) for Gram-positive bacteria. Target concentrations for synergy: peak 3–4 mcg/mL (3–4 mg/L; 6.3–8.4 μmol/L) and trough < 1 mcg/mL (1 mg/L; 2.1 μmol/L).
Linezolid	None	None	Metabolites may accumulate in severe renal impairment Monitor for hematologic AE, particularly severe thrombocytopenia Use in severe hepatic impairment not established
Nafcillin	None	If severe (see comment)	Adjustments necessary ONLY in patients with severe hepatic AND renal impairment. Monitor for potential development of AIN.
Oxacillin	If severe (see comment)	None	Monitor for potential development of AIN.
Penicillin G	Required	None	Dose increase dependent upon organism. Monitor for potential development of AIN.
Rifampin	None	Required	Assess other medications for potential interaction as rifampin a potent cytochrome P450 inducer. Inform patient of potential change in color of body fluids (ie, urine, sweat, and saliva) to orange, yellow, red, or brown.
Vancomycin	Required	None	Monitor therapeutic concentrations to guide dosage adjustments. For MRSA IE, recommend use of AUC/MIC with goal of 400–600 mg h/L (best estimation by calculation from serum peak and trough concentrations). For all other organisms, goal trough concentrations 10–20 mcg/mL (10–20 mg/L; 6.9-13.8 μmol/L) with some guidance suggesting higher levels of 15–20 mcg/mL (15–20 mg/L ; 10.4-13.8 μmol/L).
Newer and Salvage Drugs			
Ceftaroline	Required	None	Suggested dosages for off-label use in IE are higher than standard dosing (ie, 600 mg every 8 hours). Adjustments for off-labeled dosing should still be based on patient's CrCl (33%–67% reduction recommended).
Dalbavancin	Recommended	None	Half-life approximately 346 hours, dosing for IE not established.
Oritavancin	None	None	Half-life approximately 245 hours, dosing for IE not established.
Telavancin	Required	None	No therapeutic monitoring required for efficacy. Monitor for QTc prolongation and infusion-related reactions.
Streptomycin	Required	None	Used only as synergy (combination therapy) for Gram-positive bacteria if gentamicin resistance. Therapeutic concentrations vary for Gram-negative bacteria Monitor therapeutic concentrations to guide dosage adjustments Target concentrations for synergy: peak 20–35 mcg/mL (20–35 mg/L; 34–60 μmol/L) and trough < 10 mcg/mL (10 mg/L; 17 μmol/L)

[a] Gram-negative bacteria, fungal, or atypical treatments are not listed. It is suggested that an infectious diseases consultation be obtained if a patient has IE caused by one of these organisms due to the complexity and difficulty in managing these patients.

AE, adverse event; CPK, creatinine phosphokinase; CrCl, creatinine clearance.

Antimicrobial Stewardship in IE

Antimicrobial stewardship efforts in relation to IE should focus on recommendations which optimize antimicrobial management, including but not limited to, appropriate selection of empiric and definitive antimicrobial regimens, suggestion for infectious diseases/endocarditis team consultation, and ensuring adequate dosages for selected therapy. Once culture and susceptibility data are (if) available, the stewardship team can work with clinicians to tailor and maximize treatment of the patient. Patients with IE will require a prolonged treatment course; the stewardship team

Table 78–9

Cardiac Conditions Associated with the Highest Risk of Adverse Outcome from Endocarditis for Which Prophylaxis with Dental Procedures Is Reasonable[a]

- Prosthetic cardiac valve or prosthetic material used for cardiac-valve repair
- Previous IE
- Congenital heart disease (CHD)[b]
  - Unrepaired cyanotic CHD, including palliative shunts and conduits
  - Completely repaired congenital heart defect with prosthetic material or device, whether placed by surgery or by catheter intervention, during the first 6 months after the procedure[c]
  - Repaired CHD with residual defects at the site or adjacent to the site of a prosthetic patch or prosthetic device (which inhibit endothelialization)
- Cardiac transplantation recipients who develop cardiac valvulopathy

[a] *All dental procedures* involving manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa are reasonable indications for prophylaxis in patients with the conditions listed above.

[b] Except for the conditions listed above, antibiotic prophylaxis is no longer recommended for any other form of CHD.

[c] Prophylaxis is reasonable because endothelialization of prosthetic material occurs within 6 months after the procedure.

Data from Wilson W, Taubert KA, Gewitz M, et al. Prevention of infective endocarditis: guidelines from the American Heart Association. Circulation. 2007;116:1736–1754. ©2007, American Heart Association, Inc.

can provide or assist in monitoring serum antibiotic concentrations (if patient is receiving vancomycin or an aminoglycoside) and pertinent laboratory values associated with side effects (such as creatine kinase increase with daptomycin and decreased platelets with linezolid). For institutions that have an "endocarditis team," a clinical pharmacist (infectious diseases or stewardship pharmacist preferred) should assist in managing therapy throughout treatment. Additionally, the stewardship team should be aware of potential patients requiring prophylaxis for IE and provide guidance/recommendations for antimicrobial coverage prior to inpatient surgical procedures or provide education on IE prevention prior to discharge. Other preventative measures, such as vaccinations, utilized for many infectious diseases have been investigated against organisms commonly causing IE; however, to date, none have come to fruition.[18]

OUTCOME EVALUATION

KEY CONCEPT Monitoring for successful therapy is critical for this serious infection to prevent complications, prevent development of resistance, and decrease mortality. Routine assessment of clinical signs and symptoms, as well as laboratory tests (eg, repeat blood cultures), microbiologic testing, and serum drug concentrations (if appropriate), must be performed.

Resolution of signs and symptoms typically occurs within a few days to a week in most cases. Monitor the patient's temperature daily for febrile episodes, as well as other vital signs, with expected normalization of values within 2 to 3 days of antimicrobial therapy initiation.[1] Persistent signs or symptoms could be indicative of inadequate treatment or source control and/or development of resistance.

Blood cultures are the primary laboratory evaluation to assess response to therapy. Collect and monitor blood cultures every 24 to 48 hours until bacteremia is cleared; with appropriate treatment, they should become negative within 3 to 7 days. Perform additional blood cultures if the patient appears unresponsive to current therapy or upon treatment completion to confirm eradication of infection. Evaluate all susceptibility testing reports to assess appropriateness of antimicrobial therapy.

Monitor the patient for potential development of side effects based on selected therapy. For patients receiving vancomycin and/or an aminoglycoside, collect and assess appropriate serum concentrations based on the causative organism, adjusting the dosage regimen if necessary. Refer to treatment and dosage consideration Tables 78–5 to 78–8 for therapeutic target goals.

Educate patients on the necessity of prophylactic antibiotics prior to major dental treatments or GI/GU surgeries to prevent

Table 78–10

Prophylactic Regimens for Dental Procedure

		Regimen: Single Dose 30–60 Minutes Before Procedure	
Situation	**Agent**	**Adults**	**Children**
Oral	Amoxicillin	2 g	50 mg/kg
Unable to take oral medications	Ampicillin or cefazolin or ceftriaxone	2 g IM or IV	50 mg/kg IM or IV
Allergic to penicillins or ampicillin—oral	Cephalexin[a,b] or clindamycin or azithromycin or clarithromycin	2 g 600 mg 500 mg	50 mg/kg 20 mg/kg 15 mg/kg
Allergic to penicillins or ampicillin and unable to take oral medications	Cefazolin or ceftriaxone[b] or clindamycin	1 g IM or IV 600 mg IM or IV	50 mg/kg IM or IV 20 mg/kg IM or IV

[a] Or other first- or second-generation oral cephalosporin in equivalent adult or pediatric dosage.

[b] Cephalosporins should not be used in an individual with a history of anaphylaxis, angioedema, or urticaria with penicillins or ampicillin.

IM, intramuscular.

Patient Care Process

Collect Information:

- Perform a medication history review for prescription and nonprescription medications and herbal or dietary supplements.
- Determine allergies, including reaction, to medications, food, or material.
- Review medical and surgical history and findings of physical assessment.
- Review medical records and communicate with the patient to ascertain lifestyle habits, preferences and beliefs, goals for health and function, and socioeconomic factors affecting access to medication or other components of therapy.

Assess the Information:

- Determine whether patient has any risk factors for the development of IE utilizing modified Duke criteria (see Table 74–4).
- Review and document pertinent patient social, medical, and surgical history associated with development or identification of causative organisms of IE.
- Review physical exam and vital signs, relevant laboratory tests (ie, white blood cell count, differential, blood cultures), and diagnostic imaging (echocardiogram) as indicators of diagnosis and severity of the IE infection.
- Assess the empirical pharmacologic regimen for appropriate coverage of likely causative organisms, patient allergies, and potential adverse effects (eg, nephrotoxicity).
- Determine whether selected regimen is on institution's formulary. If not, is there a formulary alternative? If no alternative, is there anything specific to institution to utilize nonformulary agent?
- Determine if patient is receiving the appropriate therapy based on culture and sensitivities.

Develop a Care Plan:

- Once blood culture identification/susceptibility is reported, determine if patient is on appropriate antimicrobial therapy.
- Recommend change in therapy if the pathogen is not susceptible to current antimicrobial(s) or if patient not improving on current therapy (ie, resolution of bacteremia, afebrile, and decreasing white blood cell count).
- Determine whether drug doses are optimal for treatment but minimize development of adverse effects.
- Determine appropriate duration of treatment (timeframe based from first negative blood culture).
- Determine if lifestyle modifications are appropriate.

Implement the Care Plan:

- Educate the patients about the selected antimicrobial therapy and dosing, expected duration, possible adverse effects, and how to self-monitor for worsening of infection and adverse effects.
- Address any patient concerns about IE and its management.
- Discuss importance of lifestyle modifications if applicable.
- Determine if outpatient therapy is required and choose appropriate alternative if inpatient therapy not feasible based on frequency of dosages, lack of monitoring, or cost/insurance limitations.

Follow-Up: Monitor and Evaluate:

- Review medication efficacy and safety. Is the infection resolving? Is patient experiencing any adverse effects from their antimicrobial(s)? Are there any potential drug–drug interactions from this medication?
- Follow up with blood cultures (not needed unless clinical signs/symptoms of infection still present) and physical exam. Review medical history and any other pertinent laboratory tests and results of other diagnostic tests.
- Monitor vital signs/symptoms for return to baseline during each clinic follow-up over the duration of therapy. If continued to be abnormal, reassessment of therapy/other diagnostic testing is necessary.
- Once the infection has resolved, educate the patient on importance preventative antibiotics prior to future invasive dental procedures and to inform all healthcare providers including dentists of history of having IE.

recurrent infections. This is critical in patients with risk factors that predispose them to developing IE, such as prosthetic heart valves, other valvular defects, or previous IE.

Develop a follow-up plan to determine whether the patient has achieved a cure, which includes a clinical evaluation of signs/symptoms, repeat blood cultures, and possibly a repeat echocardiogram. Assess the patient for any adverse events throughout treatment course and at follow-up. Perform follow-up visit within a few weeks after the completion of therapy.

Abbreviations Introduced in This Chapter

AHA	American Heart Association
AIN	Allergic interstitial nephritis
AUC	Area under the concentration–time curve
CFU	Colony-forming units
CKD	Chronic kidney disease
CoNS	Coagulase-negative staphylococci
CNS	Central nervous system
CT	Computed tomography
CTA	Computed tomography angiography
ESR	Erythrocyte sedimentation rate
GI	Gastrointestinal
GU	Genitourinary
IE	Infective endocarditis
MIC	Minimum inhibitory concentration
MRI	Magnetic resonance imaging
MRSA	Methicillin-resistant *S. aureus*
MSSA	Methicillin-sensitive *S. aureus*
NBTE	Nonbacterial thrombotic endocarditis
NVE	Native-valve endocarditis
PD	Pharmacodynamic
PET	Positron emission tomography

PK	Pharmacokinetic
PRP	Penicillinase-resistant penicillins (eg, nafcillin and oxacillin)
PVE	Prosthetic-valve endocarditis
TEE	Transesophageal echocardiogram
TPN	Total parenteral nutrition
TTE	Transthoracic echocardiogram
VRE	Vancomycin-resistant enterococci
WBC	White blood cell

Tuberculosis

Rocsanna Namdar and Charles Peloquin

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Assess risk factors for developing an active tuberculosis (TB) infection.
2. Design appropriate antimicrobial regimens for the treatment of latent TB infection.
3. Design an appropriate therapeutic plan for a patient with active TB disease.
4. Distinguish among the diagnostic tests used for patients potentially infected with TB.
5. Determine appropriate monitoring parameters to evaluate the efficacy and safety of an active drug regimen for active TB.
6. Describe potential adverse reactions associated with TB medications.
7. Select patients for whom therapeutic drug monitoring (TDM) may be valuable and identify the necessary laboratory monitoring parameters for patients on anti-TB medications.

INTRODUCTION

Tuberculosis (TB) is one of the leading causes of death from infectious origin worldwide. In 2018, there were about 10 million new cases and an estimated 1.5 million deaths from TB reported.[1] Most deaths are preventable if appropriate access to health care for both diagnosis and treatment is available.

EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT Roughly one-fourth of the world's population is infected with tuberculosis; TB and drug resistance is increasing in many areas.[1] The majority of cases worldwide are found in South-East Asia (44%) and Africa (24%). In the United States, about 13 million people have latent TB infection (LTBI), evidenced by a positive skin test (**purified protein derivative** [PPD]) with no concurrent signs or symptoms of disease. PPD is an antigen derived from *Mycobacterium tuberculosis* used to determine the presence of an immune response in patients with previous exposure.

In 2019, 8920 new TB cases were reported in the United States; a 1.1% decline from 2018.[2] The most recent data from the Centers for Disease Control and Prevention (CDC) indicate that TB deaths in the United States have decreased from 2016 by 2.5% in 2017.[3] (For details, visit the CDC website at www.cdc.gov/nchstp/tb.) TB is most prevalent in large urban areas and is exacerbated by crowded living conditions.[2] Those in close physical contact with patients that have active pulmonary TB are most likely to become infected.[2,3] TB cases in California, New York, Florida, and Texas accounted for over 40% of all cases in 2018.[2] These higher numbers may reflect the high-immigration rates into these states.[2] Mexico, the Philippines, Vietnam, India, and China account for the largest numbers of these immigrants.[2] People of Asian descent represent the largest proportion of TB cases as reported by race/ethnicity accounting for 35.3% of cases reported in 2018 followed by Hispanics (29%) non-Hispanic Black patients (19.9%), and non-Hispanic White patients (11.9%). When origin of birth is considered, reported cases among US-born persons are highest among non-Hispanic Black patients (35.7%) followed by non-Hispanic White patients (30.3%); and among non-US-born persons cases are highest among Asians (48.1%) followed by Hispanics (32%).[2,3] TB is more common among men and in those that are 25 to 44 years of age.[3]

Once infected, a person's lifetime risk of developing active TB is about 10%, with about half this risk during the first 2 years.[2-4] However, this risk is elevated in young children, the elderly, and immunocompromised patients. KEY CONCEPT Human immunodeficiency virus (HIV) is the most important risk factor for active TB because the immune deficit prevents patients from containing the initial infection.[1-4] HIV-infected patients with *M. tuberculosis* infection are roughly 100 times more likely to develop active TB than normal hosts.[1,3,4]

Etiology

TB is caused by *M. tuberculosis*, a rod-shaped thin aerobic bacterium. It presents either as LTBI or as progressive active disease.[4] The latter typically causes progressive destruction of the lungs, leading to death in most patients who do not receive treatment. *M. tuberculosis* are acid-fast bacilli (AFB). Acid-fast organisms are characterized by wax-like, nearly impermeable cells walls, which often do not stain with Gram stain and cannot be decolorized by acid alcohol. The cell wall contains a high amount of mycolic acids, long-chain fatty acids, and cell wall lipids that make the wall difficult to attack with conventional antibiotics. The acid-fast stain is a differential stain used to identify acid-fast organisms.

PATHOPHYSIOLOGY

Primary Infection

KEY CONCEPT *M. tuberculosis* is transmitted from person to person by coughing or by any other aerosol-producing activities such as sneezing.[4,5] This produces small particles called "droplet nuclei" that are suspended in the air for long periods of time. Primary infection usually results from inhaling droplet nuclei that contain *M. tuberculosis*.[4,5] The progression to clinical disease depends on three factors: (a) the number of *M. tuberculosis* organisms inhaled (infecting dose), (b) the virulence of these organisms, and (c) the host's cell-mediated immune response.[4,5] If pulmonary macrophages inhibit or kill the bacilli, the infection is aborted.[5] If not, *M. tuberculosis* eventually spreads throughout the body through the bloodstream.[4,5] *M. tuberculosis* most commonly infects the posterior apical region of the lungs, where conditions are most favorable for its survival.

T lymphocytes become activated over the course of 3 to 4 weeks, producing interferon-γ (IFN-γ) and other cytokines. These stimulate microbicidal macrophages to surround the tuberculous foci and form **granulomas** to prevent further spread.[5] A granuloma is a nodular aggregation of mononuclear inflammatory cells formed when the immune system attempts to wall off foreign substances. At this point, the infection is largely under control, and bacillary replication falls off dramatically. Any remaining mycobacteria are believed to reside primarily within granulomas or within macrophages that have avoided detection and lysis, which account for the occurance of latent TB. Over 1 to 3 months, tissue hypersensitivity occurs, resulting in a positive PPD.[4,5] Approximately 95% of individuals with an intact immune system will enter into this latent phase. **KEY CONCEPT** Progressive primary disease occurs in roughly 5% of patients, especially children, the elderly, and immunocompromised patients.[6,7] This presents as a progressively worsening pneumonia and frequently spreads, leading to meningitis and other severe forms of TB, often before positive skin test (often called PPD) or IFN-γ release assays (IGRAs).[6]

Reactivation Disease

About 10% of infected patients develop reactivation TB, with half occurring in the first 2 years after infection.[4] Reactivation TB results when a previously "dormant" focus is reactivated and causes disease. Progression involves the development of caseating granulomas as a result of a vigorous immune response. Liquefaction then leads to local spread, and a pulmonary cavity results. This provides a portal to the airways and subsequently ambient air that enhances person-to-person spread. Bacterial counts in the cavities can be as high as 10^8/mL (10^{11}/L) of cavitary fluid.[4,5] Prior to the chemotherapy era, pulmonary TB usually was associated with hypoxia, respiratory acidosis, and eventually death related to asphyxia; a fate that remains all too common in poor countries where patients do not have access to effective therapy.

Extrapulmonary and Miliary Tuberculosis

Caseating granulomas, regardless of location, can spread tubercle bacilli and cause symptoms.[4] Because of muted or altered symptoms, the diagnosis of TB is difficult and often delayed in immunocompromised hosts.[4,5] HIV-infected patients may present with only extrapulmonary TB, which is uncommon in HIV-negative persons. A widely disseminated form of the disease called *miliary TB* can occur, particularly in children and immunocompromised hosts. This can be rapidly fatal and immediate treatment is required.[5]

Influence of HIV Infection on Pathogenesis

As CD4$^+$ lymphocytes multiply in response to the mycobacterial infection, HIV multiplies within these cells and selectively destroys them, gradually eliminating the TB-fighting lymphocytes.[7,8] HIV-positive patients often have negative PPD and fail to produce **cavitary lesions**, and fever may be absent. Cavitary lesions are present in a wide variety of pathological processes involving the lung and are observed radiographically as gas or fluid filled areas of the lung in the center of a nodule. Approximately 5% of HIV-infected patients with pulmonary TB who are not being treated effectively with antiretroviral medications will have positive results on acid-fast staining, yet have a normal chest radiograph. Patients coinfected with HIV and TB have a substantially higher risk of early mortality compared with HIV-negative patients with TB.[9,10]

CLINICAL PRESENTATION AND DIAGNOSIS

Culture and Susceptibility Testing

KEY CONCEPT Microscopic examination of infected material ("**sputum smear**" of material on a glass slide) is the most rapid and readily available test to detect AFB in clinical specimens. Three sputum specimens should be collected in patients suspected of pulmonary TB to increase the likelihood of finding AFB. *The sensitivity of the sputum smear is only about 45% and less for HIV-infected patients, so culture-based TB diagnosis is the current gold standard.*[4,11,12] Unfortunately, culture is much slower due to the roughly 20-hour doubling time of the bacilli. Furthermore, microscopic examination for AFB through sputum smear alone cannot determine which of over 100 mycobacterial species is present.[13] Depending on the presence of epidemiological risk factors, the usual practice is to isolate the patient and treat empirically until the presence of *M. tuberculosis* is confirmed by nucleic acid amplification (NAA) or positive culture.

Antimicrobial susceptibility testing is essential for directing proper treatment. One common method utilizing solid growth media, known as the *proportion method,* takes 3 to 8 weeks to produce results. Growth in liquid media is faster and can detect live mycobacteria in about 2 weeks.[11,12] Rapid-identification tests include NAA tests utilizing the polymerase chain reaction (PCR)[13-15]. NAA tests have been approved for use in the United States to detect *M. tuberculosis* in respiratory secretions. These tests are highly sensitive and specific for smear-positive patients and somewhat less sensitive in smear-negative patients but only need as few as 1 to 10 organisms/mL (10^3–10^4/L) to give a positive result.[13-16] The Cepheid MTB/RIF Assay performed on the Xpert System is a qualitative test designed for the rapid detection of *M. tuberculosis* and rifampin resistance.[17,18] Results are available in hours and the time for diagnosis and treatment initiation can be significantly shortened. These tests are particularly useful in limited resource settings.[19] DNA fingerprinting is performed to assist surveillance programs and contact investigations. Various techniques are employed including restriction fragment length polymorphism (RFLP) analysis, spoligotyping, and mycobacterial interspersed repeat units. These techniques exploit conserved fragments in the TB genome that change gradually over time and allow investigators to determine if strains are related to one another. Strains that are related to one another are referred to as clusters. Clusters generally indicate recent transmission and are then targeted for interventions by TB programs.[20,21]

Clinical Presentation

Fever, night sweats, weight loss, fatigue, and a productive cough are the classic symptoms of TB.[4,5] Onset may be gradual, and the diagnosis is easily missed if the symptoms are muted due to compromised immune system.[4,5] Progressive pulmonary disease leads to cavitary lesions visible on X-ray. Physical examination is nonspecific but may be consistent with pneumonia. Dullness to chest percussion, rales, and increased vocal **fremitus** may be observed on examination. Laboratory data often are uninformative, but a modest increase in the white blood cell (WBC) count with a lymphocytic predominance can be seen. Frequently, however, the physical examination is largely unremarkable.

Atypical presentations are common in patients coinfected with HIV.[4,5,9] Symptoms for these patients range from classic pulmonary to muted and nonspecific. Extrapulmonary TB typically presents either as a slowly progressive decline in the effected organ's function or commonly as a mass lesion. Lymphadenopathy is relatively common.[5,6] Abnormal behavior, headaches, or convulsions suggest tuberculous meningitis, although other acute central nervous system (CNS) infections must be excluded.[4,5]

Multidrug-resistant TB (MDR-TB) remains a public health concern. In 2017, the WHO estimated approximately 600,000 cases of TB worldwide with resistance to rifampicin, of which 82% had MDR-TB.[22] There are a number of laboratory tools available for the diagnosis of MDR-TB, including phenotypic culture-based drug susceptibility testing as well as molecular methods.[23] The Xpert MTB/RFI assay was approved by the Food and Drug Administration (FDA) in 2013. Other assays have not yet been approved for use in the United States, but several validated tests (line-probe assays, molecular beacons, and DNA sequencing) are being used. Molecular testing may be useful in patients with a high risk of having MDR-TB, very ill patients who are not improving with standard first-line therapy, and for outbreak investigations.[24]

The Elderly

Positive PPD test, fevers, night sweats, sputum production, or hemoptysis may be absent in the elderly population, making TB hard to distinguish from other bacterial and viral infections, as well as chronic lung diseases.[4,23] In contrast, mental status changes are twice as common in the elderly, and CNS disease must be considered when TB is entertained. Mortality is six times higher in the elderly, in part owing to delays in diagnosis.[4,23,25]

Children

TB in children may present as atypical bacterial pneumonia and often involves the lower and middle lobes.[4,6,26] Extrapulmonary TB is more common in children.

Prevention

The Bacille Calmette–Guérin (BCG) is a vaccine made from strains of tubercle bacilii and is used to produce immunity against human TB. It is administered in countries where TB remains common and appears to stimulate children's immune systems to ward off the most serious forms of the disease. In fact, BCG is most effective in reducing infant mortality from TB meningitis and miliary disease. BCG does not block infection, and these same children often experience reactivation TB as young adults.[26]

Skin Testing

TB skin testing with PPD (commercially available as Tubersol or Aplisol) is one of the oldest diagnostic tests still in clinical use.[4,6,8] Also known as the tuberculin skin test, the product is injected into the skin (not subcutaneously) with a fine (27-ga) needle, a technique referred to as the Mantoux method and produces a small, raised, blanched wheal to be read by an experienced professional in 48 to 72 hours. The chance of a false-negative result is increased when the patient is immunosuppressed. The CDC does not recommend the routine use of anergy panels to determine if a patient's T-cell immune system reacts to common antigens.[8,27]

Criteria for interpretation are listed in Table 79–1 and the summary of recommendations is found in Table 79-2.[6]

The "booster effect" occurs in patients who do not respond to an initial PPD test but show a positive reaction if retested 1 to

Table 79–1

Criteria for Tuberculin Positivity, by Risk Group[6]

Reaction ≥ 5 mm of Induration	Reaction ≥ 10 mm of Induration	Reaction ≥ 15 mm of Induration
HIV-infected persons	Recent immigrants (ie, within the last 5 years) from high-prevalence countries	Persons with no risk factors for TB
A recent contact of a person with TB disease	Injection drug users	
Fibrotic changes on chest radiograph consistent with prior TB	Residents and employees[a] of the following high-risk congregate settings: prisons and jails, nursing homes and other long-term facilities for the elderly, hospitals and other health care facilities, residential facilities for patients with AIDS, and homeless shelters	
Patients with organ transplants and other immunosuppressed patients (receiving the equivalent of 15 mg/day or more of prednisone for 1 month or longer, taking TNF-α antagonists)[b]	Mycobacteriology laboratory personnel, persons with the following clinical conditions that place them at high risk: silicosis, diabetes mellitus, chronic renal failure, some hematologic disorders, other specific malignancies, gastrectomy, and jejunoileal bypass Children younger than 5 years of age or infants, children, and adolescents exposed to adults at high risk	

Interpretation of IGRA Results

The interpretation of IGRAs is based on the amount of IFN-γ, in T-SPOT TB. Laboratories should provide both the qualitative and quantitative results.

- Qualitative results are reported positive, negative, indeterminate, or borderline.
- Quantitative results are reported as numerical values that include a response to the TB antigen and two controls, nil and mitogen. Quantitative results may be useful for clinical decision-making in individual cases, in combination with risk factors.

[a] For persons who are otherwise at low risk and are tested at the start of employment, a reaction of 15 mm or more of induration is considered positive.

[b] Risk of TB in patients treated with corticosteroids increases with higher dose and longer duration.

Data from Official American Thoracic Society/Infectious Diseases Society of America/Centers for Disease Control and Prevention Clinical Practice Guidelines: diagnosis of tuberculosis in children and adults. CID. 2017;64(1):111–115.

Table 79–2

Summary of Recommendations for Testing for Latent Tuberculosis Infection (LTBI)

Group	Testing Strategy	Considerations
Likely to be Infected **High** Risk of Progression (TST ≥ 5 mM)	**Adults** **Acceptable:** IGRA or TST Consider dual testing where a positive result from either result would be considered **positive** **Children ≤ 5 years of age** **Preferred:** TST **Acceptable:** IGRA or TST Consider dual testing where a positive result from either would be considered **positive**[a]	Prevalence of BCG vaccination Expertise of staff and/or laboratory Test availability Patient perceptions Staff perceptions Programmatic concerns
Likely to be Infected **Low** to **Intermediate** Risk of Progression (TST ≥ 10 mM)	**Preferred:** IGRA where available **Acceptable:** IGRA or TST	
Unlikely to be Infected (TST >15 mM)	**Testing for LTBI is not recommended** **If necessary:** **Preferred:** IGRA where available **Acceptable:** IGRA or TST **For serial testing:** **Acceptable:** IGRA or TST Consider repeat or dual testing where a negative result from either would be considered **negative**[b]	

[a] Performing a second diagnostic test when the initial test is negative is a strategy to increase sensitivity.

[b] Performing a confirmatory test following an initial positive result is based upon both the evidence that false positive results are common among individuals who are likely to be infected with TB. A second test is presumed to help identify false-positive results.

Modified from Official American Thoracic Society/Infectious Diseases Society of America/Centers for Disease Control and Prevention Clinical Practice Guidelines: diagnosis of tuberculosis in children and adults. CID. 2017;64(1):111–115.

3 weeks later.[6,24,27] In order to reduce the likelihood that a boosted reaction is misinterpreted as a new infection, the two-step method is recommended at the time of initial testing for individuals such as health care workers or nursing home residents who may be tested periodically. If the first PPD test is negative, repeat the test in 1 to 3 weeks. If the second test is positive, it is most commonly a boosted reaction, and the person should be classified as previously infected.

Newer Diagnostic Tests

The development of blood tests and IGRAs that have replaced the PPD test in the United States for individuals 5 years and older who meet the following criteria: likely to be infected with *M. tuberculosis*; low or intermediate risk of disease progression; testing for LTBI is warranted; and have history of BCG vaccine or unlikely to return to have PPD read.[6,27] These newer methods measure the release of IFN-γ in blood in response to TB antigens. The two TB blood tests approved in the United States are: the QuantiFERON-TB Gold In-Tube test (QFT-GIT) and the T-SPOT TB test (T-Spot).[27] The sensitivity of IGRAs ranges from 80% to 90%, and specificity of 95% for diagnosis of latent TB. Recent evidence suggests that prior placement of PPD can boost an IGRA. The boosting effect may wane after several months.[8,27] The IGRAs do not cause the booster phenomenon and are unaffected by BCG or infection by most non-TB mycobacteria. Results of the IGRAs are available in less than 24 hours, versus the 3 days required for the traditional PPD test. Data are limited for use of IGRAs in children younger than 5 years of age, persons recently exposed to TB, health care workers, and immunodeficient patients.[27] KEY CONCEPT The CDC has endorsed the use of IGRA tests in all circumstances where the PPD is used. IGRAs are approved for the diagnosis of LTBI in HIV-infected patients, but sensitivity is diminished.[27] Testing with both PPD and IGRA generally is not recommended but may be useful in certain situations (eg, if the initial PPD test is negative and the risk for infection, clinical suspicion, or the risk for poor outcome is high; or if the initial PPD test is positive and additional evidence of infection is required; or the patient has a low risk of infection or progression).[27,28] IGRAs, and the PPD, should not be used to rule in or rule out the diagnosis of active TB disease.[28]

Patient Encounter Part 1

HPI: RG is a 46-year-old man who presents to the medical clinic complaining of a 2-month history of a persistent cough that has become productive over the past 3 weeks. He also complains of fever, night sweats, malaise, and a 6-kg (13-lb) weight loss over the past 2 months.

PMH: HIV positive; Hypertension (HTN) × 5 years—not well controlled.

FH: Mother, age 82, alive and well, lives with RG. Father died of alcoholic liver disease 10 years ago. One brother, age 53, lives with the patient, currently undergoing chemotherapy treatment for lung cancer.

SH: Born and raised in Florida. Single. He occasionly smokes marijuana and drinks 1 to 2 glasses of wine daily. He owns his own import/export business and travels internationally to Central and South America.

Meds: Lisinopril 20 mg daily; amlodipine 5 mg daily; Atripla one daily. Patient reports that he tries to be compliant with his therapies and takes them regularly except when he travels he often forgets to take his medication.

What factors place this patient at increased risk for acquiring TB?

TREATMENT

General Approaches to Treatment

The primary treatment approach is the use of antimicrobials active against *M. tuberculosis*. For LTBI, monotherapy can be used only for patients with evidence of a positive PPD test or positive IGRA in the absence of signs or symptoms of disease. Once active disease is present, typically *four medications* must be used simultaneously from the start treatment.[4,5,8,27] The shortest duration of treatment is 4 months in the unusual case of smear- and culture-negative clinical cases of pulmonary TB, and up to 2 years of treatment may be necessary for advanced cases of MDR-TB.[27,29]

Directly observed treatment (DOT) is a method used to ensure adherence in which patients are directly observed by a health care worker while taking their anti-TB medication.[30] Case management interventions such as patient education, counseling, home visits, integration, and coordination of care with specialists as well as incentives and enablers during treatment of patients with TB disease are also encouraged. These are examples a cost-effective ways to ensure completion of treatment.

Desired Outcomes

Steps should be taken to (a) prevent the spread of TB (respiratory isolation); (b) find where TB has already spread (contact

Patient Encounter Part 2

CXR: Bilateral upper lobe infiltrates with cavitary lesions on left; small left pneumothorax

Clinical Course: The patient was admitted and placed on respiratory isolation. Three separate sputum AFB stain specimens were reported to contain 3+ AFB. IFN-γ was sent and a PPD tuberculin skin test was placed. Sputum samples were sent for AFB, fungi, and bacterial cultures and sensitivities. IFN-γ test resulted positive and after 48 hours, the PPD skin test was read as a 7-mm area of induration.

Assessment: Active pulmonary TB; pneumothorax.

Which signs, symptoms, and other findings are consistent with active TB infection?

How might HIV-positive patients present differently as compared to HIV-negative patients?

investigation); and (c) return the patient to a state of normal weight and well-being. Items (a) and (b) are performed by public health departments. Clinicians involved in the treatment of TB should verify that the local health department has notified of all new cases of TB.[8]

Pharmacologic Therapy

Treating LTBI

KEY CONCEPT The CDC and National Tuberculosis Controllers Association recommend rifampin-based regimens for the treatment of LTBI presumed to be susceptible to isoniazid or rifampin.[31] The regimens include rifampin daily for 4 months, rifampin and isoniazid daily for 3 months, or rifapentine and isoniazid once weekly for 3 months. In some instances, isoniazid may be used as an alternative for a 6- or 9-month duration of treatment. Isoniazid monotherapy regimens are associated with lower treatment completion and more adverse effects. However, isoniazid monotherapy is still the preferred regimen for the treatment of LTBI in patients with HIV infection.[32] Pyridoxine (25–50 mg/day in adults) can reduce the risk of peripheral neuropathy associated with isoniazid.[8,31,33] Treatment of LTBI reduces a person's lifetime risk of active TB from about 10% to about 1%.[8,28,31] The combination of pyrazinamide and rifampin is no longer recommended.[31,34,35] Most isoniazid resistance cases are reported amongst non-US-born individuals, and in 2018 the multidrug resistance rate reported in the United States was 1.5%.[2,3] When resistance to isoniazid and rifampin is suspected, there is no regimen proven to be effective.[33] Options for treatment of drug-resistant TB are based on suspected patterns for drug resistance and may include a fluoroquinolone.[36] Note that patients with LTBI are not infectious and there is no isolate on which to perform susceptibility testing. Susceptibility patterns must be inferred based on the most likely source of infection.

Treating Active Disease

In the United States, TB patients can receive free treatment through local health departments. Treating active TB disease requires combination chemotherapy. **KEY CONCEPT** A four-drugs treatment regimen is started with the first-line drugs for the treatment of active disease: isoniazid, rifampin, pyrazinamide, and ethambutol. Isoniazid and rifampin should always be included in the medication regimen to prevent potential drug resistance.[8,33] Drug susceptibility testing should be done on the initial isolate for all patients.[8,33] Susceptibility testing should be repeated if the patient remains culture-positive 8 weeks or more into therapy.[29]

The standard TB treatment regimen for susceptible TB is isoniazid, rifampin, pyrazinamide, and ethambutol for 2 months, followed by isoniazid and rifampin for 4 months, for a total of 6 months of treatment.[8,33] Extending the treatment duration to 9 months is recommended for patients at a greater risk of failure and relapse, including those with cavitary lesions on initial chest radiograph and positive cultures at the completion of the initial 2-month phase of treatment, as well as for patients treated initially without pyrazinamide. Ideally, treatment should be continued for at least 6 months from the time that patients convert to a negative culture.[8,33] When the patients' sputum smears convert to negative, the risk of infecting others is greatly reduced, but it is not zero.[33] Such patients can be removed from respiratory isolation if they are responding clinically. The decision to discontinue isolation should be done by medical providers experienced in TB control. Table 79–4 shows the recommended treatment regimens. Daily dosing rather than intermittent dosing is preferred; but intermittent dosing can be considered in patients with low risk of relapse and negative HIV test results. DOT is essential for more difficult to treat patients such as patients who are nonadherent, drug resistant, or with certain comorbidities.[30,34] Doses missed during an intermittent TB regimen decrease the efficacy of the regimen and increase the relapse rate.

Table 79–3

Recommendations for Regimens to Treat Latent Tuberculosis Infection[31]

Preferred Regimens
3 months isoniazid plus rifapentine given once weekly
4 months rifampin given daily
3 months isoniazid plus rifampin given daily

Adjustments to the regimen should be based on susceptibility data.[16,33] Drug resistance should be suspected in patients who have been treated previously for TB. **KEY CONCEPT** If adjustments are needed based on suspected resistance, two or more drugs with in vitro activity against the patient's isolate and that were not used previously should be added to the regimen.[16,33] Due to the risk of further drug resistance, it is critical to avoid adding only a single drug to a failing regimen.[29,33] When isoniazid and rifampin cannot be used, either because of drug resistance or intolerance, treatment durations typically become 2 years or more, regardless of immune status.[16,33] TB specialists should be consulted regarding cases of drug-resistant TB, or whenever treatment is uncertain.[33] Therapeutic drug monitoring (TDM) can direct dosing for such patients.[37] One of the proven reasons for treatment failure is malabsorption of orally administered drugs.[33,37]

Special Populations

Treatment for extrapulmonary TB is the same as for pulmonary disease. Unless contraindicated, corticosteroid treatment also should be added to the treatment regimen of TB meningitis and pericarditis. Patients with CNS TB usually are treated for 12 months.[4,33] Isoniazid and pyrazinamide cross the blood–brain barrier well, but rifampin and ethambutol tend to have low CNS penetration. TB osteomyelitis typically is treated for 9 months, occasionally with surgical débridement.[4,33] TB of the soft tissues can be treated with conventional regimens.[4,33] Patients with diabetes mellitus have been shown to have low 2-hour peak serum concentrations of antimicrobials. TDM can be considered to optimize treatment response.[38] TB in children may be treated with regimens similar to those used in adults, typically for 6 months. Some physicians extend treatment to 9 months for infants, and for those who are slow to respond or who have severe disease.[6,7,33] Pediatric doses of isoniazid and rifampin on a milligram-per-kilogram basis are higher than those used in adults (Table 79–5).[33] Pregnant women receive the usual treatment of isoniazid, rifampin, and ethambutol for 9 months.[29,33] Pyrazinamide has not been studied in large numbers of pregnant women, but anecdotal data suggest that it may be safe.[33,39] The clinician should always determine risk versus benefit and determine if a drug is safe to administer in pregnancy.

Human Immunodeficiency Virus

HIV-infected adults may receive a 6-month total treatment regimen with isoniazid, a rifamycin, pyrazinamide, and ethambutol for the first 2 months followed by isoniazid and a rifamycin for 4 months.[33,40] Some clinicians recommend extending treatment to 9 months. Rifabutin is used to reduce drug interactions with protease inhibitors and some nonnucleoside reverse transcriptase inhibitors. Integrated antiretroviral therapy (ART) is superior

Table 79–4

Drug Regimens for Microbiologically Confirmed Pulmonary Tuberculosis Caused by Drug-Susceptible Organisms[33]

	Initial Phase		Continuation Phase		
Regimen	**Drugs**	**Interval and Doses[a] (Minimal Duration)**	**Drugs[b]**	**Interval and Doses[b] (Minimal Duration)**	**Comments[c,d]**
1	Isoniazid Rifampin Pyrazinamide Ethambutol	7 days/week for 56 doses (8 weeks) or 5 days/week for 40 doses (8 weeks)[c]	Isoniazid/Rifampin	7 days/week for 126 doses (18 weeks) or 5 days/week for 90 doses (18 weeks)[c]	This is the preferred regimen for patient with newly diagnosed pulmonary tuberculosis
2	Isoniazid Rifampin Pyrazinamide Ethambutol	7 days/week for 56 doses or 5 days/ week for 40 doses (8 weeks)	Isoniazid/Rifampin	Three times weekly for 54 doses (18 weeks)[d]	Preferred alternative regimen in situations in which more frequent DOT during continuation phase is difficult to achieve
3	Isoniazid Rifampin Pyrazinamide Ethambutol	Three times weekly for 24 doses (8 weeks)	Isoniazid/Rifampin	Three times weekly for 54 doses (18 weeks)	Use regimen with caution in patients with HIV and/or cavitary disease. Missed doses can lead to treatment failure, relapse, and acquired drug resistance
4	Isoniazid Rifampin Ethambutol Pyrazinamide	7 days/week for 14 doses then twice weekly for 12 doses[e]	Isoniazid/Rifampin	Twice weekly for 36 doses (18 weeks)	Do not use twice weekly regimens in HIV-infected patients or patients with smear positive and/or cavitary disease. If doses are missed, then therapy is equivalent to once weekly, which in inferior

[a] Other combinations may be appropriate in certain circumstances; additional details are provided in the section "Recommended Treatment Regimens."

[b] When DOT is used, drugs may be given 5 days/week and the necessary number of doses adjusted accordingly. Although there are no studies that compare five with seven daily doses, extensive experience indicates this would be an effective practice. DOT should be used when drugs are administered < 7 days/week.

[c] Based on expert opinion, patients with cavitation on initial chest radiograph and positive cultures at completion of 2 months of therapy should receive a 7-month (31-week) continuation phase.

[d] Pyridoxine (vitamin B6), 25–50 mg/day, is given with INH to all persons at risk of neuropathy (eg, pregnant women; breastfeeding infants; persons with HIV; patients with diabetes, alcoholism, malnutrition, or chronic renal failure; or patients with advanced age). For patients with peripheral neuropathy, experts recommend increasing pyridoxine dose to 100 mg/day.

[e] Alternatively, some US tuberculosis control programs have administered intensive-phase regimens 5 days/week for 15 doses (3 weeks), then twice weekly for 12 dose.

DOT, directly observed therapy; EMB, ethambutol; HIV, human immunodeficiency virus; INH, isoniazid; PZA, pyrazinamide; RIF, rifampin.

Data from Centers for Disease Control and Prevention. Treatment of Tuberculosis. American Thoracic Society, CDC, and Infectious Diseases Society of America. CID. 2016:63;853–867.

to sequential ART in the treatment of naïve HIV-seropositive patients with TB.[41] The optimal timing of integrated HIV and TB therapy is influenced by the patient's immune status.[41] It is recommended to start integrated ART therapy 2 to 8 weeks after initiating anti-TB therapy in patients with CD4 cell counts less than 50/mm^3.[41] TB-HIV experts should manage such patients. Highly intermittent regimens (twice or once weekly) are not recommended for HIV-positive TB patients.[33,40] Some patients with acquired immunodeficiency syndrome (AIDS) malabsorb their oral medications, and drug interactions are common. Thus, TDM may be useful in these cases.[29,33,37]

For complete recommendations on management of TB and HIV visit the CDC website: www.cdc.gov/tb/publications/guidelines/HIV_AIDS.htm.

▶ *Multidrug-Resistant TB*

MDR-TB is caused by *M. tuberculosis* that is resistant to at least isoniazid and rifampin. If drug-resistant TB is suspected, the empiric regimen should be modified based on patterns of suspected resistance. Once susceptibilities are confirmed, regimens can be modified appropriately. Five drugs are recommended during the initial phase of treatment followed by four drugs in the continuation phase.[42] Patients with MDR-TB are at a high risk of failure and should be treated by specialists or centers with experience treating drug-resistant TB. For effective treatment of MDR-TB a 5 to 7 month intensive phase after culture conversion is recommended followed by a 15- to 21-month total treatment duration.[42] Even longer durations are recommended for patients with extensively drug-resistant TB (XDR-TB). Of note, the WHO recommendations differ slightly with regard to treatment durations. The treatment of MDR-TB is evolving with the introduction of the "BPaL" regimen, consisting of bedaquiline (which has a partially active M2 metabolite), pretomanid, and linezolid for 6 months. As new drugs are approved, MDR-TB treatments will be revised.

▶ *Renal Failure*

Isoniazid and rifampin usually do not require dose modification in renal failure.[29] Pyrazinamide and ethambutol typically are

Table 79–5

Antituberculosis Drugs for Adults and Children[33]

Drug	Daily Doses[a,b,c]	Adverse Effects	Monitoring
Isoniazid	*Adults*: 5 mg/kg *Children*: 10–15 mg/kg	Asymptomatic elevation of aminotransferases, clinical hepatitis, fatal hepatitis, peripheral neurotoxicity, CNS system effects, lupus-like syndrome, hypersensitivity, monoamine poisoning, diarrhea	LFT monthly in patients who have preexisting liver disease or who develop abnormal liver function that does not require discontinuation of drug Dosage adjustments may be necessary in patients receiving anticonvulsants or warfarin
Rifampin[d]	*Adults*: 10 mg/kg *Children*: 10–20 mg/kg	Cutaneous reactions, GI reactions (nausea, anorexia, abdominal pain), flu-like syndrome, hepatotoxicity, severe immunologic reactions, orange discoloration of bodily fluids (sputum, urine, sweat, tears), drug interactions owing to induction of hepatic microsomal enzymes	Rifampin causes many drug interactions. For a complete list of drug interactions and effects, refer to CDC website: www.cdc.gov/nchstp/tb/tb
Rifabutin[d]	*Adults*: 5 mg/kg *Children*: Appropriate dosing unknown	Hematologic toxicity, uveitis, GI symptoms, polyarthralgias, hepatotoxicity, pseudojaundice (skin discoloration with normal bilirubin), rash, flu-like syndrome, orange discoloration of bodily fluids (sputum, urine, sweat, tears)	Drug interactions are less problematic than rifampin
Rifapentine[d]	*Adults*: 10 mg/kg (continuation phase) dosed weekly *Children*: The drug is not approved for use in children < 12 yr	Similar to those associated with rifampin	Drug interactions are being investigated and are likely similar to rifampin
Pyrazinamide	*Adults*: Based on IBW: 40–55 kg: 1000 mg; 56–75 kg: 1500 mg; 76–90 kg: 2000 mg *Children*: 30–40 mg/kg	Hepatotoxicity, GI symptoms (nausea, vomiting), nongouty polyarthralgia, asymptomatic hyperuricemia, acute gouty arthritis, transient morbilliform rash, dermatitis	Serum uric acid can serve as a surrogate marker for compliance LFTs in patients with underlying liver disease
Ethambutol[e]	*Adults*: Based on IBW: 40–55 kg: 800 mg; 56–75 kg: 1200 mg; 76–90 kg: 1600 mg *Children*[c]: 15–25 mg/kg	Retrobulbar neuritis, peripheral neuritis, cutaneous reactions	Baseline visual acuity testing and testing of color discrimination Monthly testing of visual acuity and color discrimination in patients taking > 15–20 mg/kg, renal insufficiency, or receiving the drug for > 2 months
Cycloserine[f]	*Adults*: 10–15 mg/kg *Children*: 15–20 mg/kg	CNS effects	Monthly assessments of neuropsychiatric status Serum concentration may be necessary until appropriate dose is established
Ethionamide[g]	*Adults*: 15–20 mg/kg *Children*: 15–20 mg/kg	GI effects, hepatotoxicity, neurotoxicity, endocrine effects	Baseline LFTs Monthly LFTs if underlying liver disease is present TSH at baseline and monthly intervals
Streptomycin	*Adults*[h] *Children*: 15–20 mg/kg	Ototoxicity, neurotoxicity, nephrotoxicity	Baseline audiogram, vestibular testing, Romberg testing and SCr Monthly assessments of renal function and auditory or vestibular symptoms
Amikacin/kanamycin	*Adults*[h] *Children*: 15–20 mg/kg/day	Ototoxicity, nephrotoxicity	Baseline audiogram, vestibular testing, Romberg testing and SCr Monthly assessments of renal function and auditory or vestibular symptoms
Capreomycin	*Adults*[h] *Children*: 15–20 mg/kg	Nephrotoxicity, ototoxicity	Baseline audiogram, vestibular testing, Romberg testing and SCr Monthly assessments of renal function and auditory or vestibular symptoms Baseline and monthly serum K^+ and Mg^{2+}

(Continued)

Table 79–5

Antituberculosis Drugs for Adults and Children[33] (*Continued*)

Drug	Daily Doses[a,b,c]	Adverse Effects	Monitoring
p-Aminosalicylic acid (PAS)	*Adults*: 8–12 g/day in two or three doses *Children*: 200–300 mg/kg/day in two to four divided doses	Hepatotoxicity, GI distress, malabsorption syndrome, hypothyroidism, coagulopathy	Baseline LFTs and TSH TSH every 3 months
Levofloxacin[i]	Adults: 500–1000 mg daily *Children*: Not recommended	GI disturbance, neurologic effects	No specific monitoring recommended
Moxifloxacin[j]	*Adults*: 400 mg daily *Children*: Not recommended		
Bedaquiline	*Adults:* Weeks 1–2: 400 mg daily Weeks 3–24: 200 mg three times weekly *Children:* Not recommended	GI disturbances, dizziness, headache, rash, arthralgia	Serum K, Ca, Mg ECG at baseline, weeks 2, 12, 24 Weekly ECG for persons taking other QTc prolonging drugs, history of arrhythmias, hypothyroidism, uncompensated heart failure, or have serum K, Ca, or Mg below normal limits

[a] Dose per weight is based on ideal body weight. Children weighing > 40 kg should be dosed as adults.

[b] For purposes of this document adult dosing begins at age 15 years.

[c] The authors of this chapter do not agree with the use of maximum doses, since this arbitrarily caps doses for patients who otherwise might need larger doses. These maximum doses were not based on prospective studies in large or overweight individuals and do not consider patients with documented malabsorption of their medications. Clinical judgment should be used in such circumstances.

[d] Higher doses of rifampin and rifapentine are being studied. Rifabutin dose may need to be adjusted when there is concomitant use of protease inhibitors or nonnucleoside reverse transcriptase inhibitors.

[e] The drug can likely be used safely in older children but should be used with caution in children < 5 years of age, in whom visual acuity cannot be monitored. In younger children, ethambutol at the dose of 15 mg/kg/day can be used if there is suspected or proven resistance to isoniazid or rifampin.

[f] It should be noted that, although this is the dose recommended generally, most clinicians with experience using cycloserine indicate that it is unusual for patients to be able to tolerate this amount. Doses are often divided. Serum concentration measurements are often useful in determining the optimal dose for a given patient.

[g] Doses are often divided. The single daily dose can be given at bedtime or with the main meal.

[h] Dose: 15 mg/kg/day, and 10 mg/kg in persons older than 59 years of age. Usual dose: 750–1000 mg administered intramuscularly or intravenously, given as a single dose 5–7 days/week and reduced to two or three times per week after the first 2–4 months or after culture conversion, depending on the efficacy of the other drugs in the regimen.

[i] The long-term (more than several weeks) use of levofloxacin in children and adolescents has not been approved because of concerns about effects on bone and cartilage growth. However, most experts agree that the drug should be considered for children with tuberculosis caused by organisms resistant to both isoniazid and rifampin. The optimal dose is not known.

[j] The long-term (more than several weeks) use of moxifloxacin in children and adolescents has not been approved because of concerns about effects on bone and cartilage growth. The optimal dose is not known.

Data from Official American Thoracic Society/Centers for Disease Control and Prevention/Infectious Diseases Society of America Clinical Practice Guidelines: treatment of drug-susceptible tuberculosis. Clin Infect Dis. 2016;63(7):853–867.

reduced to three times weekly to avoid accumulation of the parent drug (ethambutol) or metabolites (pyrazinamide).[43] Renally cleared TB drugs include the aminoglycosides (typically amikacin), ethambutol, cycloserine, and levofloxacin.[44,45] Linezolid also has significant renal clearance. With renal impairment, dosing intervals need to be extended for these drugs. TB drugs should be administered after hemodialysis, and in this case three-times weekly regimens may be more convenient. Serum concentration monitoring should be performed for cycloserine and ethambutol to avoid dose-related toxicities in renal failure patients.[43,44]

▸ *Hepatic Failure*

Hepatically cleared TB drugs include isoniazid, rifampin, pyrazinamide, ethionamide, and *p*-aminosalicylic acid.[29] Bedaquiline and pretomanid also are hepatically cleared. Ciprofloxacin and moxifloxacin are about 50% cleared by the liver. Isoniazid, rifampin, pyrazinamide, and to a lesser degree ethionamide, *p*-aminosalicylic acid, and rarely ethambutol may cause hepatotoxicity.[29] These patients require close monitoring, and serum concentration monitoring may be the most accurate way to dose them.[37]

Patient Encounter Part 3

Based on the information provided, what are the goals of therapy for this patient?

Select and recommend a therapeutic plan for treatment of this patient's TB infection. What drugs, dose, schedule, and duration of therapy are best for this patient?

Who else should be tested? How should any contacts infected by this patient be evaluated and treated?

▸ *TB Drugs*

Detailed information regarding TB drugs can be accessed at the following references.[29,33,37] A summary is provided in Table 79–5.[33] Isoniazid, rifampin, ethambutol and pyrazinamide are the key drugs. Other drugs are used in selected circumstances. Quinolones eventually may be used as first-line drugs but currently are not.[45,46] In 2012, the FDA approved bedaquiline for the treatment of MDR-TB.[47] Bedaquiline may be used in adults with confirmed pulmonary MDR-TB when an effective treatment regimen cannot otherwise be provided.[48] It should be used with three or more drugs that are active against the patient's isolate. Bedaquiline carries a black-box warning due to prolongation of QTc interval. Baseline and follow-up electrocardiograms are recommended. For treatment of XDR-TB, other new therapies drugs such as pretomanid have been approved for use in combination with bedaquiline and linezolid.[49] Additional second-line options available in the United States include imipenem, meropenem, with clavulanate (as found in amoxicillin/clavulanate) used to protect either carbapenem from MTB's beta-lactamase.

OUTCOME EVALUATION

Effectiveness of TB therapy is determined by AFB smears and cultures. Sputum samples should be sent for AFB staining and microscopic examination (sputum smears) every 1 to 2 weeks until two consecutive smears are negative. This provides early evidence of a response to treatment.[33] Once on maintenance therapy, *sputum cultures* can be performed monthly until two consecutive cultures are negative, which generally occurs over 2 to 3 months. If sputum cultures continue to be positive after 2 months, repeat drug susceptibility testing and check serum concentrations of the drugs.

Patient Encounter Part 4

Based on the information provided, which clinical and laboratory parameters should be monitored in this patient to determine efficacy and avoid toxicity?

Is this patient a candidate for therapeutic drug monitoring? Why or why not?

KEY CONCEPT Nonadherence is a significant problem in the treatment of TB.[33,34,49] DOT should be used because it is difficult to determine which patients will be noncompliant with the complex regimen.[33,34,49] DOT also provides increased opportunities to observe the patient for any apparent toxicities, thus improving overall care.[49] DOT now can be performed using video or wireless methods, as well as in-person observation.

Patient weight should be monitored in addition to radiographic and bacteriological testing. Serum chemistries, including blood urea nitrogen (BUN), creatinine, aspartate transaminase (AST),

Patient Care Process

Collect Information:

- Obtain a thorough medical, social, and medication history. (Medical risk factors, eg, immunocompromised and living conditions.)
- Obtain necessary laboratory tests, cultures, and radiology to determine active infection. (Collect appropriate samples for smears and cultures, tuberculin skin test/interferon γ.)
- Review physical assessment findings.
- Speak with the patient, obtain risk factors for infection and developing active TB (travel, living conditions, immune status, etc).

Assess the Information:

- Assess the patient's risk factors and signs and symptoms to determine whether the patient might be infected with TB.
- Assess potential for risk of transmission
- Assess immune status
- Based on physical examination, medical history, laboratory tests and cultures, and X-rays, determine whether the patient has an active TB infection.
- Assess the efficacy, safety, and patient adherence of required pharmacotherapy.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- Isolate the patient with active disease to prevent the spread of the disease.
- Select and recommend appropriate antituberculosis treatment. Consider susceptibility, HIV status, drug interactions, type of TB infection, etc.
- Choose medication doses that are optimal for the patient. Consider renal function, liver function, potential for drug interactions etc.
- Consider DOT.
- Identify the index case that infected the patient, identify all persons infected by both the index case and the new case of TB, and the complete appropriate treatments for those individuals.

Implement the Care Plan:

- Provide education and review drugs, duration, dose, frequency, and side effects of selected medications.
- Educate the patient about the importance of compliance with the regimen and the risks of noncompliance.
- Ensure adherence to the treatment regimen by the patient.

Follow-up: Monitor and Evaluate:

- Follow up at required intervals to obtain AFB stains to evaluate the effectiveness of treatment.
- Review susceptibilities when available and modify treatment regimen as determined by susceptibility results.

Review patient adherence to treatment plan

- Continue treatment for at least 6 months from the time that the patient converts to a negative culture.
- Consider TDM if no clinical improvement or if risk of inadequate absorption, elimination, or drug interactions.

and alanine transaminase (ALT) and a complete blood count with platelets at baseline and periodically, thereafter, should be checked depending on the presence of other factors that may increase the likelihood of toxicity (eg, advanced age, alcohol abuse, and pregnancy).[33] Suspect hepatotoxicity in patients whose transaminases exceed five times the upper limit of normal (ULN), or whose total bilirubin exceeds 3 mg/dL (51 μmol/L), and in patients with symptoms such as nausea, vomiting, and jaundice with liver enzyme elevations of more than three times ULN. At this point, discontinue the offending agents. Typically, all TB drugs are stopped, followed by the sequential reintroduction of the drugs, along with frequent testing of liver enzymes. This usually is successful in identifying the offending agent; other agents may be continued.[33]

Therapeutic Drug Monitoring

TDM is the use of serum drug concentrations to optimize therapy.[33,37] Patients with uncomplicated, drug-susceptible TB generally do well. Pharmacokinetic variability of anti-TB drugs can contribute to poor outcomes despite adherence. TDM can be used to shorten the time to response and to treatment completion. The evidence to support the use of TDM in the treatment of TB is growing.[37] TDM can assist in patients failing appropriate DOT (no clinical improvement after 2–4 weeks or smear-positive after 4–6 weeks). Patients with AIDS, diabetes, impaired renal clearance, and various GI disorders often fail to absorb or eliminate these drugs properly and are also candidates for TDM. Drug concentrations in patients with hepatic or renal disease should be monitored, given their potential for toxicities. In the treatment of MDR-TB, TDM may be particularly useful.[29] Finally, TDM of the TB and HIV drugs is perhaps the most logical way to untangle the complex drug interactions. For a complete list of drug interactions, visit the CDC website: www.cdc.gov/tb/publications/guidelines/TB_HIV_DRUGS/default.htm.[50] In particular, interactions between the rifamycins (eg, rifampin, rifapentine, and rifabutin) and the HIV protease inhibitors and nonnucleoside reverse transcriptase inhibitors are common and require dose and frequency modifications in many cases. Because these are constantly being updated, the preceding link is an excellent way to keep up with frequent changes.

Abbreviations Introduced in This Chapter

AFB	Acid-fast bacilli
AIDS	Acquired immunodeficiency syndrome
ALT	Alanine transaminase
ART	Antiretroviral therapy
AST	Aspartate transaminase
BCG	Bacille Calmette–Guérin
CDC	Centers for Disease Control and Prevention
CNS	Central nervous system
DOT	Directly observed therapy
HIV	Human immunodeficiency virus
HTN	Hypertension
IGRA	Interferon-γ release assay
IFN	Interferon
LTBI	Latent tuberculosis infection
MDR-TB	Multidrug-resistant tuberculosis
NIDDM	Noninsulin-dependent diabetes mellitus
PCR	Polymerase chain reaction
PPD	Purified protein derivative
RFLP	Restriction fragment length polymorphism
TB	Tuberculosis
TDM	Therapeutic drug monitoring
ULN	Upper limit of normal
WBC	White blood cell
XDR-TB	Extremely drug-resistant tuberculosis

Gastrointestinal Infections

Megan M. Seddon and Jamie J. Kisgen

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the epidemiology and clinical presentation of commonly encountered gastrointestinal (GI) infections.
2. Summarize common risk factors associated with the development of a GI infection.
3. Given a patient with a GI infection, develop an individualized treatment plan.
4. Outline the impact of widespread antimicrobial resistance on current treatment recommendations for GI infections.
5. Discuss the effect of host immunosuppression on the risk of disease complications and treatment strategies associated with GI infections.
6. Educate patients on appropriate prevention measures of GI infections, including vaccinations.

INTRODUCTION

With suggested prevalence approaching one episode per person per year in resource-rich settings, and greater prevalence in low- and middle-income countries, most readers will have personal experience with gastrointestinal (GI) infections.[1] Culprits in GI infections comprise a diverse group of microorganisms, including bacteria, viruses, and protozoans. Corresponding clinical presentations are also nuanced, but acute diarrheal illness is a common unifying theme. Syndromes of acute diarrhea or vomiting are described by the overarching term, gastroenteritis. Diarrhea, in turn, is most commonly defined as greater than three loose stools in a 24-hour period.

A useful way to broadly classify GI infections is to divide them into inflammatory or noninflammatory categories. Inflammatory diarrhea is caused by invasive or cytotoxin-producing bacteria, or in some cases by amoebae (eg, *Entamoeba histolytica*), which damage the intestinal mucosa. Characteristics of GI infections caused by these organisms include frequent, painful, small-volume bowel movements containing blood and mucus. Fever is another common, though not universal, symptom. Syndromes of inflammatory diarrhea are also frequently referred to as dysentery. Pathogens implicated in inflammatory GI infections are listed in Table 80–1.

Noninflammatory GI infections are often caused by viruses but may also be associated with protozoans and enterotoxin-producing bacteria. Rather than tissue destruction, noninflammatory diarrhea is differentiated by disruption of the intestinal processes of absorption or secretion. This difference in pathophysiology explains the contrasting clinical characteristics of large-volume, watery diarrhea associated with abdominal cramping or vomiting. Individuals with noninflammatory GI infections are often normothermic or have only mild fever.

A thorough patient history may yield further clinical clues, leading the clinician to suspect involvement of a particular pathogen even prior to diagnostic testing. Examples of patient risk factors or exposures associated with specific organisms are listed in Table 80–2. These may include ingestion of contaminated food or water, animal exposures, recent antibiotic therapy, or immunocompromising conditions.

KEY CONCEPT While risk factors and implicated pathogens are varied, rehydration is the foundation of therapy for those suffering from dehydration due to GI infections, with oral rehydration therapy (ORT) preferred when possible (Table 80–3). Indication for antimicrobial therapy is dependent on many factors (to be discussed further in the following sections), including severity of illness and suspected pathogen.

INFLAMMATORY GASTROINTESTINAL INFECTIONS

SHIGELLA

Epidemiology

Shigella causes bacillary dysentery, which refers to diarrheal stool containing pus and blood. Shigellosis is endemic in most developing countries and is the most important cause of bloody diarrhea worldwide. It is estimated to cause between 80 and 160 million cases and 270,000 deaths each year, the majority of which occur in children less than 5 years old.[2,3] There are approximately 500,000 infections each year in the United States; it is a particular problem in daycare centers and in areas with crowded living conditions or poor sanitation. Most cases of shigellosis are transmitted through the fecal–oral route. Activities that may lead to shigellosis include handling diapers, ingesting pool water, or consuming vegetables from a sewage-contaminated field. *Shigella* transmission from contaminated food and water, although less common, is associated with large outbreaks.

Pathogenesis

Shigella organisms are nonmotile, nonlactose-fermenting, gram-negative rods and are members of the Enterobacteriaceae family.

Table 80–1

Gastrointestinal Pathogens Causing Acute Diarrhea

Mechanism	Location	Illness	Stool Findings	Examples of Pathogens Involved
Noninflammatory (enterotoxin)	Proximal small bowel	Watery diarrhea	No fecal leukocytes; mild or no increase in fecal lactoferrin	*Vibrio cholerae*, enterotoxigenic *Escherichia coli* (LT and/or ST), enteroaggregative *E. coli, Clostridium perfringens, Bacillus cereus, Staphylococcus aureus, Aeromonas hydrophila, Plesiomonas shigelloides*, rotavirus, norovirus, enteric adenoviruses, *Giardia lamblia, Cryptosporidium* spp., *Cyclospora* spp., microsporidia
Inflammatory (invasion or cytotoxin)	Colon or distal small bowel	Dysentery or inflammatory diarrhea	Fecal polymorphonuclear leukocytes; substantial increase in fecal lactoferrin	*Shigella* spp., *Salmonella* spp., *Campylobacter jejuni*, enterohemorrhagic *E. coli*, enteroinvasive *E. coli, Yersinia enterocolitica, Listeria monocytogenes, Vibrio parahaemolyticus, Clostridioides difficile, A. hydrophila, P. shigelloides, Entamoeba histolytica, Klebsiella oxytoca*
Penetrating	Distal small bowel	Enteric fever	Fecal mononuclear leukocytes	*Salmonella* Typhi, *Y. enterocolitica*

Abbreviations: LT, heat-labile enterotoxin; ST, heat-stable enterotoxin.

Table 80–2

Exposure or Condition Associated With Pathogens Causing Diarrhea

Exposure or Condition	Pathogen(s)
Foodborne	
Foodborne outbreaks in hotels, cruise ships, resorts, restaurants, catered events	Norovirus, nontyphoidal *Salmonella*, *Clostridium perfringens*, *Bacillus cereus*, *Staphylococcus aureus*, *Campylobacter* spp, ETEC, STEC, *Listeria*, *Shigella*, *Cyclospora cayetanensis*, *Cryptosporidium* spp
Consumption of unpasteurized milk or dairy products	*Salmonella*, *Campylobacter*, *Yersinia enterocolitica*, *S. aureus* toxin, *Cryptosporidium*, and STEC. *Listeria* is infrequently associated with diarrhea, *Brucella* (goat milk cheese), *Mycobacterium bovis*, *Coxiella burnetii*
Consumption of raw or undercooked meat or poultry	STEC (beef), *C. perfringens* (beef, poultry), *Salmonella* (poultry), *Campylobacter* (poultry), *Yersinia* (pork, chitterlings), *S. aureus* (poultry), and *Trichinella* spp (pork, wild game meat)
Consumption of fruits or unpasteurized fruit juices, vegetables, leafy greens, and sprouts	STEC, nontyphoidal *Salmonella*, *Cyclospora*, *Cryptosporidium*, norovirus, hepatitis A, and *Listeria monocytogenes*
Consumption of undercooked eggs	*Salmonella*, *Shigella* (egg salad)
Consumption of raw shellfish	*Vibrio* species, norovirus, hepatitis A, *Plesiomonas*
Exposure or contact	
Swimming in or drinking untreated fresh water	*Campylobacter*, *Cryptosporidium*, *Giardia*, *Shigella*, *Salmonella*, STEC, *Plesiomonas shigelloides*
Swimming in recreational water facility with treated water	*Cryptosporidium* and other potentially waterborne pathogens when disinfectant concentrations are inadequately maintained
Healthcare, long-term care, prison exposure, or employment	Norovirus, *Clostridioides difficile*, *Shigella*, *Cryptosporidium*, *Giardia*, STEC, rotavirus
Child care center attendance or employment	Rotavirus, *Cryptosporidium*, *Giardia*, *Shigella*, STEC
Recent antimicrobial therapy	*C. difficile*, multidrug-resistant *Salmonella*
Travel to resource-challenged countries	*Escherichia coli* (enteroaggregative, enterotoxigenic, enteroinvasive), *Shigella*, Typhi and nontyphoidal *Salmonella*, *Campylobacter*, *Vibrio cholerae*, *Entamoeba histolytica*, *Giardia*, *Blastocystis*, *Cyclospora*, *Cystoisospora*, *Cryptosporidium*
Exposure to house pets with diarrhea	*Campylobacter*, *Yersinia*
Exposure to pig feces in certain parts of the world	*Balantidium coli*
Contact with young poultry or reptiles	Nontyphoidal *Salmonella*
Visiting a farm or petting zoo	STEC, *Cryptosporidium*, *Campylobacter*
Exposure or condition	
Age group	Rotavirus (6–18 months of age), nontyphoidal *Salmonella* (infants from birth to 3 months of age and adults >50 years with a history of atherosclerosis), *Shigella* (1–7 years of age), *Campylobacter* (young adults)
Underlying immunocompromising condition	Nontyphoidal *Salmonella*, *Cryptosporidium*, *Campylobacter*, *Shigella*, *Yersinia*
Hemochromatosis or hemoglobinopathy	*Y. enterocolitica*, *Salmonella*
AIDS, immunosuppressive therapies	*Cryptosporidium*, *Cyclospora*, *Cystoisospora*, microsporidia, *Mycobacterium avium*–intercellulare complex, cytomegalovirus
Anal-genital, oral-anal, or digital-anal contact	*Shigella*, *Salmonella*, *Campylobacter*, *E. histolytica*, *Giardia lamblia*, *Cryptosporidium* as well as sexually transmitted infections

Abbreviations: ETEC, enterotoxigenic *Escherichia coli*; STEC, Shiga toxin–producing *Escherichia coli*.

Table 80–3

Clinical Assessment of Degree of Dehydration in Children Based on Percentage of Body Weight Loss

Variable	Mild (3%–5%)	Moderate (6%–9%)	Severe (10% or More)
Blood pressure	Normal	Normal	Normal to reduced
Quality of pulses	Normal	Normal to slightly decreased	Moderately decreased
Heart rate	Normal	Increased	Increased (bradycardia in severe cases)
Skin turgor	Normal	Decreased	Decreased
Fontanelle	Normal	Sunken	Sunken
Mucous membranes	Slightly dry	Dry	Dry
Eyes	Normal	Sunken orbits/decreased tears	Deeply sunken orbits/decreased tears
Extremities	Warm, normal capillary refill	Delayed capillary refill	Cool, mottled
Mental status	Normal	Normal to listless	Normal to lethargic to comatose
Urine output	Slightly decreased	< 1 mL/kg/hour	< 1 mL/kg/hour
Thirst	Slightly increased	Moderately increased	Very thirsty
Fluid replacement	ORT 50 mL/kg over 2–4 hours	ORT 100 mL/kg over 2–4 hours	Lactated Ringer 40 mL/kg in 15–30 minutes, then 20–40 mL/kg if skin turgor, alertness, and pulse have not returned to normal *or* lactated Ringer or normal saline 20 mL/kg, repeat if necessary, and then replace water and electrolyte deficits over 1–2 days, followed by ORT 100 mL/kg over 4 hours

From Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill; 2014:1951–1967.

They are separated into four serogroups (A, B, C, and D), with *Shigella sonnei* (serogroup D) responsible for most shigellosis cases in the United States.[3] Infection with *Shigella* occurs after ingestion of as few as 10 to 100 organisms, which may explain the ease of person-to-person spread. Symptoms develop about 1 to 2 days after contracting the bacteria.[4]

Shigella strains invade intestinal epithelial cells, with subsequent multiplication, inflammation, and destruction. This organism only rarely invades the bloodstream; however, bacteremia can occur in malnourished children and immunocompromised patients and is associated with a mortality rate as high as 20%.[9]

Treatment and Monitoring

In April 2017 and June 2018, the CDC issued health advisories describing the emergence of *Shigella* strains with elevated MIC values for ciprofloxacin in the United States.[5,6] The CDC no longer recommends that antibiotics be routinely prescribed for *Shigella* infections. Antibiotic therapy should be reserved for patients who develop severe illness (eg, invasive disease, hospitalization), are immunocompromised, or when public health officials advise treatment in an outbreak situation (eg, day care, food handlers, nursing homes).[3,5] Although treatment can shorten the duration of symptoms by 1 to 2 days, shigellosis is generally a self-limited infection, and unnecessary treatment with antibiotics promotes further resistance. Empiric therapy for *Shigella* should be considered for immunocompetent patients with documented fever, abdominal pain, bloody diarrhea, and bacillary dysentery (frequent scant bloody stools, fever, abdominal cramps, tenesmus).[7] Azithromycin, fluoroquinolones, and ceftriaxone are considered first-line therapy for the treatment of shigellosis in adults. If treatment failure from any agent is suspected, an infectious diseases specialist should be consulted to identify an appropriate antibiotic. Due to concerns for resistance, patients with travel-related shigellosis should be treated empirically with first-line therapy until antimicrobial susceptibility data are available. In children, oral azithromycin or parenteral ceftriaxone are considered preferable to fluoroquinolones for first-line therapy. Antimotility medications (eg, loperamide) are not recommended as they can worsen symptoms. All shigellosis cases should be reported to the local health department.[5]

Clinical Presentation and Diagnosis of Shigellosis

- Biphasic illness
  - Early—high fever, watery diarrhea without blood
  - Later—after approximately 48 hours, colitis develops with urgency, **tenesmus**, and **dysentery**
    - Low-grade fever
    - More frequent small-volume stools ("fractional stools")
    - Vomiting (35%)
- Complications of shigellosis
  - **Proctitis** or rectal prolapse—more common in infants and young children
  - Intestinal obstruction
  - Colonic perforation
  - Bacteremia—more common in children
  - Metabolic disturbances
  - Neurologic disease—most commonly seizures (approximately 10% of patients)
  - Hemolytic–uremic syndrome (HUS)
- Microscopic examination of stool is extremely useful and reveals multiple polymorphonuclear leukocytes and red blood cells (RBCs). Diagnosis is usually confirmed by stool culture

SALMONELLA

Epidemiology

Salmonella are gram-negative facultative rods that cause a wide variety of disease manifestations. *Salmonella enterica* (serotypes Typhi and Paratyphi A and B) cause typhoid (or enteric) fever. Although typhoid fever is now a rare disease in the United States with approximately 350 culture-confirmed cases reported per year, these infections cause an estimated 30 million cases and 215,000 deaths annually worldwide.[8,9] Typhoid fever is most commonly acquired from water or food contaminated by feces from an infected person. The incubation period is 6 to 30 days; illness onset is insidious with gradually increasing fatigue and fever. Nontyphoidal *Salmonella* (NTS) are important causes of reportable food-borne infection. There are an estimated 1.35 million cases of NTS illness annually in the United States, and almost 153 million worldwide.[9,10] Annual mortality rates are 420 and 57,000, respectively. The highest incidence is in those younger than 1 year of age, older than 65 years of age, or those with HIV/AIDS. Foods commonly associated with infection include raw meat, poultry, eggs, dairy, and unwashed fruit and vegetables.[11,12] Exotic pets, especially reptiles, are an increasing source of human salmonellosis. NTS strains may also result in bacteremia and focal disease, such as endovascular infections, osteomyelitis, meningitis, and septic arthritis.[9,12] Recurrent *Salmonella* bacteremia is an AIDS-defining illness.

Risk factors for salmonellosis include extremes of age, malnutrition, immunosuppression, and genetic factors.[12,13] Proper food handling and storage can help prevent *Salmonella* gastroenteritis. Effective handwashing is important, especially when handling eggs and poultry.

Clinical Presentation and Diagnosis of Salmonellosis

Gastroenteritis

- Onset 8 to 48 hours after ingestion of contaminated food
- Fever, diarrhea, and cramping
- Stools are loose, moderate volume, and without blood
- Headache, myalgias, and other systemic symptoms can occur
- Certain underlying conditions (eg, AIDS, inflammatory bowel disease, and prior gastric surgery) predispose the patient to more severe disease

Enteric Fever

- Febrile illness 5 to 21 days after ingestion of contaminated food or water, which may be persistent and high grade. A relative bradycardia may be noted at the fever peak.
- Chills, diaphoresis, headache, anorexia, cough, weakness, sore throat, dizziness, muscle pain, and diarrhea may be present before onset of fever
- Rose spots, a coated tongue, and/or hepatosplenomegaly may be noted
- Intestinal hemorrhage or perforation, leukopenia, anemia, and subclinical disseminated intravascular coagulopathy may occur
- Culture of stool, blood, or bone marrow for *Salmonella* species is helpful

Treatment and Monitoring

▶ *Gastroenteritis*

Gastroenteritis from NTS is usually self-limited, and antibiotics have no proven value in uncomplicated patients.[7,9] Patients respond well to ORT. Symptoms typically diminish in 3 to 7 days without sequelae. Antibiotic use may result in a higher rate of chronic carriage and relapse. Antimicrobial use should be limited to preemptive therapy among patients at higher risk of extraintestinal spread or invasive disease. These include neonates (up to 3 months of age), persons over 65 years old, those with atherosclerosis, immunocompromised patients, or patients with cardiac or significant joint disease.[7] Antibiotic options should be based on susceptibility information and include ceftriaxone, ciprofloxacin, trimethoprim/sulfamethoxazole, or amoxicillin. Antimotility agents should not be used.

▶ *Enteric Fever*

Treatment of enteric fever with antibiotics can shorten the clinical course and reduce the risk of death.[9,14] The current drug of choice for typhoid fever in adults is a fluoroquinolone, such as ciprofloxacin; however, ceftriaxone should be considered in patients with invasive disease or those who are at risk of a fluoroquinolone-resistant infection. Azithromycin or ceftriaxone are preferred in children. The recommended adult dose of ciprofloxacin for uncomplicated typhoid fever is 500 mg orally twice daily for 5 to 7 days; however, decreased susceptibility to ciprofloxacin is a significant problem in many parts of the world. In the United States, *Salmonella* spp. with decreased ciprofloxacin susceptibility are associated with travel to Southeast Asia.[11] If ciprofloxacin resistance is suspected or confirmed, ceftriaxone may be used; however, this agent may be less suitable in some low- and middle-income countries due to cost and route of administration. Azithromycin is an effective alternative for uncomplicated typhoid fever.[12,13] Of note, patients may continue to have fever for up to 3 to 5 days after initiating antibiotic therapy.

Two unconjugated typhoid vaccines are available for use in the United States; however, neither is licensed by the FDA for the prevention of paratyphoid fever. Both vaccines provide 50% to 80% efficacy against *Salmonella* serotype Typhi infection but offer no protection against Paratyphi infection. Immunization is recommended for travelers going to endemic areas such as Latin America, Asia, and Africa; household contacts of chronic carriers; and laboratory personnel who frequently work with *Salmonella* serotype Typhi.[14] Vaccination is increasingly important for travelers to consider since the growth of multidrug-resistant strains of *Salmonella* serotype Typhi have become common in many regions.

▶ *Bacteremia and Focal Infections*

Due to concern for resistance, treatment of *Salmonella* bacteremia or focal infections should be initiated with both a third-generation cephalosporin (eg, ceftriaxone) and a fluoroquinolone (eg, levofloxacin, ciprofloxacin).[12] Once susceptibilities are determined, therapy can be streamlined to a single, narrow-spectrum agent. If there is no evidence of an endovascular infection, therapy for bacteremia should continue for 7 to 14 days. For patients with suspected meningitis, high-dose ceftriaxone is preferred because of its optimal penetration of the blood–CSF barrier. Osteomyelitis and joint infections, often associated with sickle cell anemia, are difficult to eradicate and require longer durations of antimicrobial therapy (at least 4–6 weeks).

Patient Encounter 1

A 20-year-old man with a medical history significant for sickle cell anemia presents to his local emergency department (ED) with a 2-day history of episodes of fever and chills. He also reports a 2-week history of pain and loss of range of motion in his right knee. When asked about medication allergies, he reports a reaction of GI upset to amoxicillin–clavulanate. Upon admission, the physician inquires about pets in the home. The patient reports he has a pet box turtle which has been with him since childhood. STAT blood cultures are positive for nontyphoidal *Salmonella* (NTS).

What risk factors are present in this patient that may have predisposed him to developing Salmonella bacteremia and probable joint infection?

What empiric therapy would you recommend? Are there any special considerations regarding duration of therapy?

CAMPYLOBACTER

Epidemiology

Campylobacter jejuni is the most commonly identified cause of bacterial gastroenteritis worldwide. In the United States, this organism accounts for an estimated 1.5 million infections, 13,000 hospitalizations, and 100 deaths annually.[16] Risk factors for *Campylobacter* infection include consumption of contaminated foods of animal origin, especially undercooked poultry or other foods that are cross-contaminated by raw poultry meat during food preparation; unpasteurized milk; contaminated water; foreign travel; contact with farm animals and pets; and the use of antimicrobial therapy.[17] People should be instructed to wash their hands after contact with raw meats and animals.

In developed countries, there are two distinct age peaks for Campylobacter infection: younger than 1 year of age and 15 to 44 years of age, with a mild male predominance. In developing countries, *Campylobacter*-associated diarrhea is primarily a pediatric disease.

Pathophysiology

Campylobacter spp. are gram-negative bacilli that have a curved or spiral shape. *Campylobacters* are sensitive to stomach acidity; as a result, diseases or medications that buffer gastric acidity may increase the risk of infection. The infectious inoculum for *C. jejuni* is low, similar to that for *Salmonella* spp. After an incubation period, infection is established in the jejunum, ileum, colon, and rectum.

Clinical Presentation and Diagnosis of Campylobacteriosis

- Incubation period of 1 to 7 days.
- A brief prodrome of fever, headache, and myalgias is followed by crampy abdominal pain, a high fever, and several bowel movements per day, which may be watery or bloody.
- The abdominal pain and tenderness may be localized, and pain in the right lower quadrant may mimic acute appendicitis. Abdominal pain is more prevalent in *Campylobacter* infection than in either *Shigella* or *Salmonella* infections.
- Tenesmus occurs in approximately 25% of patients.
- Fecal leukocytes and red blood cells (RBCs) are detected in the stools of 75% of infected individuals. Diagnosis of *Campylobacter* is established by stool culture.

Treatment

Effective fluid and electrolyte replacement is the cornerstone of therapy for patients with *Campylobacter* infection.[7,17] In most cases, this can be accomplished with the use of oral glucose–electrolyte solutions. Antibiotic therapy is not needed in most patients who are immunocompetent since the disease is self-limiting, lasting a week or less. Antibiotics should be considered in patients with high fevers, symptoms lasting longer than 1 week, pregnancy, extraintestinal infection, or immunocompromising conditions.

Azithromycin is the recommended first-line drug (500 mg orally daily for 3 days) for the treatment of *Campylobacter* infections.[7,17] A fluoroquinolone (ciprofloxacin 500 mg orally twice daily for 5–7 days) may also be considered; however, the widespread use of these agents in food animals has resulted in fluoroquinolone-resistant *Campylobacter* strains worldwide. Choice of agent may depend on travel history and risk of resistance in certain countries. *Campylobacter fetus* is the most commonly identified species in patients with bacteremia, which primarily occurs in patients who are elderly or immunocompromised.[17] In addition, focal infections such as cellulitis, vascular infections, meningitis, and abscesses may be present. For these serious infections, treatment with a third-generation cephalosporin, gentamicin, ampicillin, or a carbapenem is recommended.[19] Antimotility agents should be avoided because they may prolong the duration of symptoms and have been associated with worse outcomes. Postinfectious complications associated with *Campylobacter* infection can include reactive arthritis, irritable bowel syndrome (IBS), and Guillain–Barré syndrome (GBS).

ENTEROHEMORRHAGIC *ESCHERICHIA COLI*

Epidemiology

KEY CONCEPT Blood in the stool indicates the possibility of inflammatory mucosal disease of the colon such as enterohemorrhagic *Escherichia coli* (EHEC), a pathogenic subgroup of Shiga toxin–producing *E. coli* (STEC) and an important cause of bloody diarrhea in the United States. Acute hemorrhagic colitis has been primarily associated with the O157:H7 serotype.[18] This serotype is responsible for large outbreaks of infection, has higher rates of complications, and appears to be more pathogenic than non-EHEC STEC strains. The spectrum of disease associated with *E. coli* O157:H7 includes bloody diarrhea, which is seen in up to 95% of patients; nonbloody diarrhea; hemolytic–uremic syndrome (HUS); and thrombotic thrombocytopenic purpura (TTP).[19]

An estimated 265,000 STEC infections occur each year in the United States.[20] Serotype O157:H7 causes about one-third of these infections. Very young children and the elderly are more likely to develop severe illness and HUS; however, healthy older children and young adults can also become seriously ill.[18] Outbreaks of diarrhea due to *E. coli* O157:H7 and other STECs have occurred following ingestion of contaminated beef, unpasteurized milk, vegetables (eg, alfalfa sprouts, coleslaw, and lettuce), and apple juice. The most important reservoir for *E. coli* O157:H7 is the GI tract of cattle. Person-to-person transmission also occurs, and swimming in infant pools or contaminated lakes or drinking contaminated municipal water are additional risk

Clinical Presentation and Diagnosis of EHEC

- Incubation period of 3 to 5 days
- Bloody stools
- Leukocytosis is often present; fever is frequently absent
- Abdominal tenderness
- HUS in 2% to 10% of patients (especially children 1–5 years of age and the elderly in nursing homes); develops on average 1 week after the onset of diarrhea

factors. The incidence of diagnosed *E. coli* O157:H7 infections in the United States is greater among rural populations and usually occurs in summer and autumn months.

Pathophysiology

The infectious inoculum of EHEC is very low, between 1 and 100 colony-forming units (CFUs). The major virulence factor for EHEC is the production of two Shiga-like cytotoxins (Shiga toxin [Stx] I and II), which are responsible for vascular damage and systemic effects such as HUS. Adhesion mediates initial attachment of EHEC to intestinal epithelial cells. Following attachment, these organisms produce lesions on individual intestinal epithelial cells in the small or large intestine resulting in diarrhea.

Treatment

The only recommended treatment of EHEC infection is supportive, including fluid and electrolyte replacement, usually in the form of ORT.[7,18] Most illnesses resolve in 5 to 7 days. Patients should be monitored for the development of HUS.[19] Antibiotics are currently contraindicated because they can induce the expression and release of toxin. Antimotility agents should be avoided because they delay clearance of the pathogen and toxin, which increases the risk of systemic complications. The incidence of HUS has declined in recent years and nonsteroidal anti-inflammatory drugs (NSAIDs) are increasingly recognized as an important contributor to acute kidney injury in infected children, especially if volume depleted.

Prevention of EHEC infection is especially important because no therapeutic interventions are available to lessen the risk of the development of HUS. Hamburgers should be cooked thoroughly until the temperature of the thickest part of the patty is 72°C. All surfaces and utensils that contact raw meat should be washed thoroughly before reuse. Fruits and vegetables should be washed thoroughly, especially those that will not be cooked. Handwashing is also very important and should include the supervision of handwashing by children in daycare centers.

CLOSTRIDIOIDES DIFFICILE

Epidemiology

Clostridioides difficile (*C. difficile; formerly Clostridium difficile*) infection (CDI) is the most common healthcare-associated infection and the primary cause of hospital-acquired infectious diarrhea. In 2017, an estimated 223,900 cases of CDI occurred in hospitalized patients, which led to 12,800 deaths and attributable healthcare costs of $1 billion.[10] Strategies to reduce CDI have led to decreases in healthcare-associated cases; however, community-associated cases have not decreased. Patients with community-associated CDI are often younger, lack traditional risk factors, and generally have less severe disease compared with those with hospital-acquired infections.[21] Common risk factors for hospital-acquired CDI include increasing age, severe underlying illness, intensive care unit admission, gastric acid suppression, and exposure to antimicrobials, especially broad-spectrum, multiple-drug regimens. **KEY CONCEPT** Healthcare-associated CDI is almost always associated with antimicrobial use; therefore, unnecessary and inappropriate antibiotic therapy should be avoided. Key strategies to reduce the incidence of CDI include improving antibiotic use via antimicrobial stewardship as well as infection prevention and control procedures. These include, but are not limited to, handwashing with soap and water and healthcare facility cleaning and disinfection. Clindamycin, fluoroquinolones, cephalosporins, carbapenems, and penicillins are antibiotics most commonly associated with CDI; however, almost all antibiotics except aminoglycosides have been implicated.[22]

Pathophysiology

C. difficile, a Gram-positive, spore-forming anaerobe, is spread by the fecal–oral route, and patient-to-patient spread is an important mode of transmission within the hospital.[23] The organism is ingested either as the vegetative form or spores, which can survive for long periods in the environment and can traverse the acidic stomach. In the small intestine, spores germinate into the vegetative form. Once the GI tract is colonized with spores, disruption of the gut flora, which occurs with antibiotic therapy, allows *C. difficile* to proliferate. Toxin production is essential for the disease to occur and is responsible for the inflammation, fluid and mucus secretion, and mucosal damage that lead to diarrhea or colitis. After treatment, up to 30% of patients will develop recurrence of diarrhea and require retreatment. The risk of recurrence increases with each subsequent episode. Multiple risk factors have been linked to recurrent CDI, including impaired adaptive host response, particularly to the *C. difficile* toxins, infection with unique strains associated with epidemic outbreaks, lack of diversity in the patient's gut microbiome, and repeat or continued exposure to antimicrobials.

Treatment

Patients who develop CDI while receiving an antibiotic should have the antibiotic discontinued, if possible.[23] The use of concurrent antibiotics during CDI therapy, or soon thereafter, lowers the chances of a clinical cure and increases the risk of recurrence.[24] If antimicrobial therapy must continue, an attempt should be made to switch the patient to an agent with a lower risk of CDI.[22] Clinical practice guidelines recommend that initial antimicrobial therapy should be based on the severity of illness and whether it is an initial episode, first recurrence, or two or more recurrences.[25] Severe disease is defined as either a white blood cell count greater than 15,000 cells/mL or serum creatinine greater than 1.5 mg/dL. The clinical definition of fulminant disease is a patient with CDI who presents with hypotension or shock, ileus, or megacolon.

Oral vancomycin (125 mg orally four times daily for 10 days or 10mg/kg/dose four times daily for children) or fidaxomicin (200 mg orally twice daily for 10 days) are recommended as first-line drug therapy for the treatment of an initial episode of nonsevere or severe CDI.[23] Metronidazole (500 mg orally three times daily for 10 days or 7.5 mg/kg/dose every 6 hours for children) is no longer considered first line and should only be considered in patients with nonsevere disease, and access to vancomycin or fidaxomicin is limited.[25] For the treatment of fulminant CDI, a higher dose of vancomycin (500 mg orally by mouth or via nasogastric tube four times daily) may be combined with IV metronidazole (500 mg every 8 hours). Vancomycin may be given as

Clinical Presentation and Diagnosis of CDI

- Symptoms can start as early as the first day of antimicrobial therapy or several weeks after antibiotic therapy is completed
- Asymptomatic carriage
- Diarrhea:
  - Acute watery diarrhea with lower abdominal pain, low-grade fever, and mild or absent leukocytosis
  - Mild, with only three or four loose watery stools per day
- *C. difficile* toxins are present in stool, but sigmoidoscopic examination is normal
- Colitis:
  - Profuse, watery diarrhea with 5 to 15 bowel movements per day, abdominal pain, abdominal distention, nausea, and anorexia
  - Left or right lower quadrant abdominal pain and cramps that are relieved by passage of diarrhea
  - Dehydration and low-grade fever
  - Sigmoidoscopic examination may reveal a nonspecific diffuse or patchy erythematous colitis with or without pseudomembranes
- Toxic megacolon: Suggested by acute dilation of the colon to a diameter greater than 6 cm, associated systemic toxicity, and the absence of mechanical obstruction. It carries a high mortality rate
- Fulminant colitis: Acute abdomen and systemic symptoms such as fever, tachycardia, dehydration, and hypotension. Some patients have marked leukocytosis (up to 40×10^3 white blood cells/mm^3 [40×10^9/L]). Diarrhea is usually prominent but may not occur in patients with paralytic ileus and toxic megacolon.
- Recurrent disease:
  - Risk factors include increased age, recent abdominal surgery, increased number of *C. difficile* diarrheal episodes, and leukocytosis
  - About 10% to 30% of patients develop a second episode of CDI within 2 months of the initial diagnosis
- In most cases, *C. difficile* toxin testing of an unformed stool specimen effectively establishes the diagnosis. It should be noted that three or more loose stools without alternative explanation, including laxative use in the preceding 48 hours, should be documented prior to obtaining *C. difficile* testing. Stool culture is the most sensitive test, but it is not clinically practical due to slow turnaround time. Enzyme immunoassay (EIA) testing for toxin A and B is rapid, but less sensitive, and no longer routinely used as a standalone test. Many labs now use newer tests, such as EIA detection of glutamate dehydrogenase (GDH) combined with an EIA toxin test or nucleic acid amplification test (NAAT). In some cases, a two- or three-step method, using a combination of NAAT plus EIA and/or GDH, is used to improve positive predictive value. Leukocytosis, hypoalbuminemia, and fecal leukocytes are nonspecific but suggestive of *C. difficile* infection
- In selected patients, sigmoidoscopy, colonoscopy, or abdominal CT scan can provide useful diagnostic information

a retention enema (500 mg in 100 mL of normal saline every 6 hours) if an ileus is present. The use of antimotility agents (eg, loperamide, diphenoxylate/atropine) should be avoided in most cases due to the concern for precipitating toxic megacolon. Surgical intervention may be lifesaving, particularly in cases complicated by toxic megacolon or colonic perforation.

The recurrence rate after an initial episode of CDI is approximately 10% to 30%, with the highest risk within the first 2 weeks.[25] Continuous use of acid suppression therapies or reexposure to antimicrobial agents increases the risk of CDI recurrences.[26] Although there are no differences in initial clinical cure, fidaxomicin has been shown to decrease the risk of recurrence

Patient Encounter 2

A 65-year-old woman with a history of breast cancer (diagnosed 15 years ago; currently in remission) and hypertension presents to the hospital complaining of abdominal discomfort and acute diarrhea for the last 3 days. Over the last 24 hours, she states she has had at least 6 bouts of loose, watery diarrhea. She thought it might be due to "something she ate," but it has begun to concern her because it does not seem to be going away. Upon chart review, you note that she was recently admitted to the hospital 2 weeks ago for a urinary tract infection. She received intravenous antibiotic therapy (ceftriaxone) for 3 days and was subsequently discharged on an additional 7 days of oral therapy (ciprofloxacin). She also received pantoprazole at that time for "stress ulcer prophylaxis," which was continued at discharge with an outpatient prescription. During this admission, she is noted to be afebrile, her white blood cell count is 12,800 cells/mL, and her serum creatinine is 1.3 mg/dL (99.2 μmol/L), which is stable upon comparison with her previous hospital admission. Due to her recent history of antibiotic use and new-onset diarrhea, a stool sample is sent to the microbiology lab for a *C. difficile* toxin PCR. Home medications include amlodipine 10mg orally once daily and pantoprazole 40 mg orally once daily.

Should this patient be given loperamide (Imodium) to decrease her diarrhea while the C. difficile toxin PCR is pending?

The C. difficile toxin PCR report comes back from the lab and is positive. What antimicrobial therapy should you recommend for this patient?

What is the recommended duration of therapy for her CDI?

Would you recommend any changes to her current medications?

Assuming this patient is successfully treated for her CDI, what is the risk of the infection recurring? If it does recur, what antimicrobial agent should be recommended to treat the first recurrence?

Table 80–4

Agents Responsible for Acute Viral Gastroenteritis and Diarrhea

Virus	Peak Age	Peak Time	Duration	Transmission	Symptoms
Rotavirus	6 months–2 years	Winter	3–8 days	Fecal–oral, water, food	Diarrhea, vomiting, fever, abdominal pain
Enteric adenovirus	< 2 years	Year-round	7–9 days	Fecal–oral	Diarrhea, respiratory symptoms, vomiting, fever
Astrovirus	< 7 years	Winter	1–4 days	Fecal–oral, water, shellfish	Vomiting, diarrhea, fever, abdominal pain
Noroviruses	> 5 years	Variable	12–24 hours	Fecal–oral, food, aerosol	Nausea, vomiting, diarrhea, abdominal cramps, headache, fever, chills, myalgia

Modified from Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 8th ed. New York, NY: McGraw-Hill; 2011:1951–1967.

compared or oral vancomycin in patients. This decrease comes at a higher acquisition cost. Patients with recurrent CDI may be treated with either a prolonged taper or pulsed dosing of oral vancomycin administered over 2 to 8 weeks or fidaxomicin for 10 days. Patients with multiple recurrent CDI, refractory to vancomycin and fidaxomcin, may be a candidate for fecal microbiota transplantation. Fecal microbiota transplantation (FMT) has a reported efficacy of about 90% in preventing recurrent CDI and should be considered in patients with multiple recurrent episodes of CDI.[25] In 2016, the FDA approved bezlotoxumab, a human monoclonal antibody that binds to *C. difficile* toxin B, to reduce recurrence of CDI in patients at high risk of recurrence. This drug is administered as a single infusion (10 mg/kg), but it is important to note it is not an antibacterial drug and must be used in conjunction with antibacterial drug treatment.[27] Rifaximin, administered directly following a course of metronidazole or vancomycin, may be an option for the prevention of recurrent episodes of CDI in some patients.

Strict infection control measures, including contact precautions, should be instituted for all patients with CDI. Environmental cleaning with chlorine-containing agents should be used to eliminate *C. difficile* spores. Because alcohol is ineffective in killing spores, it is essential that healthcare workers wash their hands with soap and water rather than using alcohol-based hand sanitizers. Meticulous handwashing is the single most important strategy to decrease the patient-to-patient transmission of *C. difficile*. Although some systematic reviews have concluded that the use of probiotics may help prevent CDIs,[28] randomized controlled trials (RCTs) have failed to do so.[29] Probiotics should not be recommended for the prevention of CDI in hospitalized patients without additional evidence from RCTs.

NONINFLAMMATORY GASTROINTESTINAL INFECTIONS

Though the syndrome of profuse watery diarrhea they cause is usually self-limited, pathogens causing noninflammatory GI infections accounted for more than 1.3 million deaths worldwide in 2015 and were the fourth leading cause of death in children less than 5 years of age.[30] **KEY CONCEPT** Of these pathogens, viruses are the most common cause of noninflammatory gastroenteritis. Many viruses are implicated, including noroviruses, rotaviruses, astroviruses, enteric adenoviruses, and coronaviruses (Table 80–4). This section will focus on two of the most common, noroviruses and rotaviruses. *Cryptosporidium*, a common protozoan cause of noninflammatory GI infections, and enterotoxin-producing bacterial pathogens will also be highlighted.

NOROVIRUS

It is estimated, on average, a resident of the United States will experience five norovirus episodes in their lifetime.[31] Noroviruses are the most common cause of epidemic diarrheal illness, accounting for one-third of viral gastroenteritis in the United States and 90% of viral gastroenteritis outbreaks worldwide.[32] The ability of this group of viruses to survive extremes of temperature and many common chlorine or alcohol-based cleaning products explains their tendency to cause not only sporadic cases, but also epidemics. Outbreaks may occur in healthcare settings

Clinical Presentation and Diagnosis of Norovirus Infection

- Symptom onset may be rapid or gradual
- Abdominal cramping and nausea are common first symptoms
- Moderate, nonbloody diarrhea (up to four to eight stools per day)
- Low-grade fever present in approximately 50% of cases
- Other manifestations may include headache, malaise, and myalgias
- Symptoms typically last 48 to 72 hours and are usually self-limiting
- Those less than 5 or greater than 85 years of age or individuals with immunocompromising conditions may have more severe disease
- Often a clinical diagnosis is done based on history and symptoms, though definitive diagnosis can be made by polymerase chain reaction (PCR) of the stool

Clinical Presentation and Diagnosis of Rotavirus Infection

- Incubation period of 2 days
- 2- to 3-day **prodrome** of fever and vomiting
- Profuse diarrhea without blood or leukocytes (up to 10–20 stools per day)
- Severe dehydration
- Anorexia
- Fever may be present
- Presentation in adults may vary from asymptomatic to nonspecific symptoms of headache, malaise, and chills to severe diarrhea, nausea, and vomiting
- Diagnosis can be made by polymerase chain reaction (PCR) of the stool

or in the community—particulary in close-proximity groups (cruise ships, day cares, etc)—and are most frequent in the winter months. Transmission is multifaceted with viral spread possible through contaminated food or water, person-to-person contact, or through contaminated surfaces or objects (ie, *fomites*). Person-to-person spread via the fecal–oral route is thought to be the most common mode of transmission.

There is no current targeted antiviral therapy against noroviruses. Subsequently, as with many other causes of gastroenteritis, rehydration therapy and other symptomatic management for pain or nausea are the foundations of treatment. There is lack of evidence to support the use of antimotility agents for norovirus infection, and these should generally be avoided in pediatric and elderly populations due to potential for adverse effects. When possible, immunocompromised patients with severe disease may need to undergo lightening of their immunosuppression.

ROTAVIRUS

Rotavirus is the leading cause of childhood gastroenteritis and death worldwide, with an estimated 128,500 attributable deaths in 2016.[33] Highest mortality rates are reported in the very young and in resource-limited settings. Most infections occur in children between 6 months and 2 years of age, and typically during the winter season, though adults may be infected as well. Almost all children will experience at least one episode of rotavirus infection before 5 years of age. Person-to-person transmission occurs through the fecal–oral route.

The mechanism of diarrhea has not been clearly elucidated, but theories include a reduction in the absorptive surface along with impaired absorption owing to cellular damage, enterotoxigenic effects of a rotavirus protein, and stimulation of the enteric nervous system.

The cornerstone of rotavirus treatment is supportive care and rehydration with ORT or IV fluids. Antimotility and antisecretory agents should not be used owing to their potential side effects in children and the self-limited nature of the disease. **KEY CONCEPT** Two oral rotavirus vaccines are currently approved by the FDA, *RotaTeq* and *Rotarix*. Since their introduction in 2006, these vaccines have reduced diarrhea-related healthcare use in children by as much as 80% and have conferred protection on unvaccinated children (herd immunity). This reduction in healthcare usage has resulted in an estimated annual savings of 121 to 231 million USD.[34] The CDC Advisory Committee on Immunization Practices recommends vaccination at 2, 4, and 6 months for *RotaTeq* and 2 and 4 months for *Rotarix*. There is a small risk of **intussusception** from rotavirus vaccination within a week or 2 of the first two doses. This risk is estimated to be between 1 in 20,000 and 1 in 100,000 infants who receive the vaccine.[35]

CRYPTOSPORIDIUM

Epidemiology

Cryptosporidiosis has been recognized as a human disease since the 1970s, with increasing importance in the 1980s and 1990s because of its association with HIV/AIDS as an opportunistic

Clinical Presentation and Diagnosis of Cryptosporidiosis

General

- 7- to 10-day incubation period
- Profuse, watery diarrhea with mucus but not blood or leukocytes that lasts for approximately 2 weeks
- Nausea, vomiting, fever, and abdominal cramps may accompany the diarrhea
- Simplest method of diagnosis is detection of oocysts by modified acid-fast staining of a stool specimen. Standard ova and parasite test does not include *Cryptosporidium*

Immunocompetent

- May manifest as asymptomatic disease, acute diarrhea, or persistent diarrhea lasting for several weeks
- Usually self-limiting

Immunocompromised

- May manifest as asymptomatic disease, chronic diarrhea lasting at least 2 months, or fulminant infection with at least 2 L of watery stool per day
- In HIV-infected individuals, asymptomatic disease is more common in those with a $CD4^+$ cell count greater than 200 cells/mm^3 (200×10^6/L), and fulminant infection is more common in those with a $CD4^+$ cell count of less than 50 cells/mm^3 (50×10^6/L)

Patient Encounter 3

A young woman comes into your pharmacy to pick up a pediatric oral electrolyte solution recommended by her child's doctor for her 2-year-old's mild dehydration. Her child has been ill with gastroenteritis for the last week. About a week and half prior to the onset of symptoms, the family had visited a water park, and she had played with the toddler in the kiddie pools. She describes the child's bowel movements as large-volume and watery. According to the local news, the water park has been temporarily closed due to an outbreak of similar symptoms in other children. The mother wants to know if there are any medications that could be used to treat her child besides the oral rehydration therapy.

Based on the history of illness, including recent exposures, what organism is a likely pathogen causing the child's gastroenteritis?

What discussion points could you include in your conversation with the mother regarding indication for antimicrobial treatment of this pathogen?

What counseling points would be important to include regarding potential duration of illness and measures to prevent autoinfection?

infection. *Cryptosporidium* is now recognized as a major cause of diarrhea in children, especially those less than 2 years old[36] and has been linked with childhood malnutrition and death in resource-limited settings. Studies using PCR and antigen detection have identified *Cryptosporidium* in 15% to 25% of children with diarrhea, which is often prolonged (7–14 days) or persistent (> 14 days).[37] Incident rates have also increased in the United States, which is partially attributed to recreational water park outbreaks and likely reflects increased use of communal swimming venues (eg, lakes, swimming pools, and water parks) by young children.[38] Cryptosporidiosis is spread person to person, usually via the fecal–oral route; by animals, particularly cattle and sheep; and through the environment, especially water.

Pathophysiology

Cryptosporidium is an intracellular protozoan parasite that is capable of completing its entire life cycle within one host. Humans become infected upon ingestion of the oocysts, and autoinfection and persistent infections are possible owing to repeated life cycles within the GI tract. As few as 10 to 100 oocysts can cause infection.

Treatment

In general, immunocompetent persons and those with asymptomatic infection do not require antimicrobial therapy. In patients with HIV/AIDS, the optimal therapy is restoration of immune function through the use of antiretroviral therapy (ART). For persons in whom antimicrobial therapy is deemed necessary or patients living with HIV/AIDS in whom ART is ineffective, a combination of an antimicrobial and an antidiarrheal agent is recommended.[37]

Nitazoxanide is the only FDA-approved agent for the treatment of cryptosporidiosis in adults and children 1 year and older. This agent has demonstrated efficacy in cryptosporidiosis (eg, higher rates of diarrhea resolution and oocyst-free stools compared to placebo) in immunocompetent persons and patients living with HIV/AIDS. Patients who are infected with both HIV and *Cryptosporidium* usually require longer therapy durations and higher doses than immunocompetent patients. An alternative agent that may be considered is paromomycin, a nonabsorbable aminoglycoside, though evidence of its long-term success in patients is limited.[37]

ENTEROTOXIN-PRODUCING BACTERIA AND FOOD POISONING

Each year in the United States, approximately 76 million food-borne illnesses occur, leading to 325,000 hospitalizations and more than 5000 deaths. Many bacterial and viral pathogens that have been discussed previously in this chapter (eg, *Salmonella*, *Shigella*, *Campylobacter*, *E. coli*, and noroviruses) can cause food poisoning. Other bacteria that can cause food-borne illness include *Staphylococcus aureus*, *C. perfringens*, *Clostridium botulinum*, and *Bacillus cereus* (Table 80–5). Food poisoning should be suspected if at least two individuals present with similar symptoms after the ingestion of a common food in the prior 72 hours.

Table 80–5

Food Poisonings

Organism	Onset (Hours)	Associated Foods	Duration	Symptoms	Treatment
Staphylococcus aureus	1–6	Salad, pastries, ham, poultry	12 hours	Nausea, vomiting	Supportive
Bacillus cereus—emetic	0.5–6	Rice, noodles, pasta, pastries	24 hours	Vomiting	Supportive
Bacillus cereus—diarrheal	8–16	Meats, vegetables, soups, sauces, milk products	24 hours	Diarrhea, abdominal pain	Supportive
Clostridium perfringens (type A)	8–12	Meats, poultry	24 hours	Nausea; abdominal cramps; profuse, watery diarrhea	Supportive
Clostridium botulinum	18–24	Canned fruits, vegetables, meats, honey, salsa, relish	Weeks	Acute GI symptoms followed by symmetric, descending, flaccid paralysis; death is possible	Supportive (including mechanical ventilation); trivalent antitoxin

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements.
- Identify allergies or rashes to medications and other substances.
- Review the medical history and physical assessment findings. In a child, immunization records are especially important.
- Speak with the patient to assess cultural beliefs, health goals, or socioeconomic factors that may affect medication access, vaccination, and other aspects of care.

Assess the Information:

- Determine if the patient is taking any substance that could interact with prescription medications (eg, vitamins, OTC medications, herbals, probiotics).
- Based on medical history, determine if the patient has risk factors for GI disorders, such as diarrhea and *C. difficile* colitis.
- Based on physical examination and review of systems, identify signs or symptoms associated with diarrhea or possible *C. difficile* infection.
- Determine the patient's weight history and determine if weight loss has occurred.
- Determine the cause of any weight loss (eg, anorexia, dehydration, insufficient calories).
- Determine adherence to current medication regimen.
- Identify potential adverse drug events or drug interactions with medication regimen.
- Review current evidence-based guideline recommendations.

Develop a Care Plan:

- Evaluate drug therapy options based on the patient's diagnosis.
- Discuss treatment options with the prescriber.
- Determine whether immunizations are needed in the near future.

Implement the Care Plan:

- Determine if the patient has insurance coverage, if applicable, and if recommended agents are included in the health system's formulary.
- Educate the patient about changes in drug therapy, appropriate administration of medications, potential adverse effects associated with the new antibiotic, and how to manage and report adverse effects that may occur.
- Dialogue with patient about concerns or past problems taking medications; suggest possible solutions.
- Indicate what actions to take if the patient vomits the dose or forgets to take a dose.
- Counsel patient on the recognition of symptoms of *C. difficile* infection, serious diarrhea, and dehydration, and actions to take if these occur, including notification of the patient's primary care physician.
- Discuss importance of taking the medications as prescribed as well as importance of routine vaccinations.

Follow-up: Monitor and Evaluate:

- Follow up assessing for symptoms of chronic diarrhea.

Abbreviations Introduced in This Chapter

CDC	Centers for Disease Control and Prevention
CDI	*Clostridioides difficile* infection
CFUs	Colony-forming units
EHEC	Enterohemorrhagic *Escherichia coli*
ESBL	Extended-spectrum beta-lactamase
FMT	Fecal microbiota transplantation
HUS	Hemolytic–uremic syndrome
ORT	Oral rehydration therapy
MIC	Minimum inhibitory concentration
NSAID	Nonsteroidal anti-inflammatory drug
NTS	Nontyphoidal *Salmonella*
PPI	Proton pump inhibitor
STEC	Shiga toxin–producing *E. coli*
TTP	Thrombotic thrombocytopenic purpura
WHO	World Health Organization

Intra-Abdominal Infections

Joseph E. Mazur and Melanie Smith Condeni

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Define and differentiate between primary and secondary intra-abdominal infections (IAIs).
2. Describe the microbiology typically seen with primary and secondary IAIs.
3. Describe the clinical presentation typically seen with primary and secondary IAIs.
4. Describe the role of culture and susceptibility information for diagnosis and treatment of IAIs.
5. Recommend the most appropriate drug and nondrug measures to treat IAIs.
6. Recommend an appropriate antimicrobial regimen for treatment of primary and secondary IAIs.
7. Describe the patient-assessment process during the treatment of IAIs.
8. Introduce the concepts of antimicrobial stewardship programs (ASPs) and antimicrobial de-escalation as it pertains to the treatment of IAIs.

INTRODUCTION

Intra-abdominal infections (IAIs) are those contained within the peritoneal cavity or retroperitoneal space. The peritoneal cavity extends from the undersurface of the diaphragm to the floor of the pelvis and contains the stomach, small bowel, large bowel, liver, gallbladder, and spleen. The duodenum, pancreas, kidneys, adrenal glands, great vessels (aorta and vena cava), and most mesenteric vascular structures reside in the retroperitoneum, which is the anatomical space in the abdominal cavity behind the peritoneum. IAIs may be generalized or localized. Localized IAIs may be contained within visceral structures, such as the liver, gallbladder, spleen, pancreas, kidney, or female reproductive organs. Two generalized types of IAI are discussed throughout this chapter: peritonitis and abscess. **Peritonitis** is defined as the acute inflammatory response of the peritoneal lining to microorganisms, chemicals, irradiation, or foreign-body injury.

An **abscess** is a purulent collection of fluid separated from surrounding tissue by a wall consisting of inflammatory cells and adjacent organs. It usually contains necrotic debris, bacteria, and inflammatory cells. Peritonitis and abscess differ considerably in presentation and approach to treatment.

EPIDEMIOLOGY AND ETIOLOGY

Peritonitis may be classified as primary, secondary, or tertiary. Primary peritonitis, also called spontaneous bacterial peritonitis, is an infection of the peritoneal cavity without an evident source of bacteria from the abdomen.[1,2] In secondary peritonitis, a focal disease process is evident within the abdomen. Secondary peritonitis may involve perforation of the gastrointestinal (GI) tract (possibly due to ulceration, ischemia, or obstruction), postoperative peritonitis, or posttraumatic peritonitis (eg, blunt or penetrating trauma). Tertiary peritonitis occurs in critically ill patients and is an infection that persists or recurs at least 48 hours after apparently adequate management of primary or secondary peritonitis. Factors related to the development of tertiary peritonitis are not well described although it is more often associated with opportunistic and nosocomial pathogens.

- **KEY CONCEPT** Most IAIs are secondary infections that are caused by a defect in the GI tract that must be treated by surgical drainage, resection, and/or repair. The prevalence of primary peritonitis is 10% to 30% in hospitalized patients with alcoholic cirrhosis.[3] Patients undergoing continuous ambulatory peritoneal dialysis (CAPD) average one episode of peritonitis every 2 years.[4] The majority of these are related directly to the peritoneal dialysis (PD) rather than nondialysis-related intra-abdominal or systemic processes. Secondary peritonitis may be caused by perforation of a peptic ulcer, traumatic perforation of the stomach, small or large bowel, uterus, or urinary bladder. It may also be caused by appendicitis, pancreatitis, diverticulitis, bowel infarction, inflammatory bowel disease, cholecystitis, operative contamination of the peritoneum, or diseases of the female genital tract such as septic abortion, postoperative uterine infection, endometritis, or salpingitis. Appendicitis is one of the most common causes of IAI.[5]

Primary peritonitis in adults occurs most commonly in association with alcoholic cirrhosis, especially in the end stage, or with ascites caused by postnecrotic cirrhosis, chronic active hepatitis, acute viral hepatitis, congestive heart failure, malignancy, systemic lupus erythematosus, and nephrotic syndrome. It also may result from the use of a peritoneal catheter for dialysis with renal failure or central nervous system (CNS) ventriculoperitoneal shunting for hydrocephalus. Abscesses are the result of chronic inflammation and may occur without preceding generalized peritonitis. They may be located within the peritoneal cavity or in a visceral organ and may vary in size, taking a few weeks to years to form.

Patient Encounter 1, Part 1

A 47-year-old female with a history of COPD, cirrhosis, and atrial fibrillation presents to the emergency room with chief complaints of worsening breathing and a weight gain of 10 kg over the last month. Her current medications are: spironolactone 25 mg orally daily, prednisone 25 mg orally daily, lactulose 30 mL orally titrated at home to 1 to 2 bowel movements per day, budesonide–formoterol (160–4.5 mcg/puff) inhaler two puffs inhaled twice daily, diazepam 5 mg orally twice daily, and apixaban 5 mg orally twice daily. The patient only speaks fluent Russian as her main language and no English.

PMH: COPD, cirrhosis, atrial fibrillation

Meds: Obtained from patient's outpatient pharmacy: Spironolactone 25 mg orally daily, prednisone 25 mg orally daily, lactulose 30 mL orally titrated at home to 1 to 2 bowel movements per day, budesonide–formoterol inhaler two puffs inhaled twice daily, diazepam 5 mg orally twice daily, and apixaban 5 mg orally twice daily

SOC: Divorced, occasional cannabis use

PE:

Abdomen soft and distended, positive bowel sounds with 2 days of loose stools. Neuro exam—patient is altered and not able to speak coherently and has asterixis, Skin—spider angiomas and jaundiced. Rest of the physical examination is noncontributory.

VS: T 101.3°F (38.0°C), BP 90/65 mm Hg, P 135 beats/min, RR 16 breaths/min, Wt 170 lb (67.7 kg), Ht 5′2″ (175 cm)

Labs: Hct 14.0% (0.140), Hgb 6.2 g/dL (62 g/L; 3.8 mmol/L), WBC 20 × 10^3/mm^3 (20 × 10^9/L), serum creatinine 1.4 mg/dL (123 μmol/L), BUN 20 mg/dL (7.14 mmol/L), Na 125 mEq/L (125 mmol/L), K 4.2 mEq/L (4.9 mmol/L), Cl 98 mEq/L (98 mmol/L), CO_2 22 mEq/L (22 mmol/L), total bilirubin 2.2 mg/dL (37.6 μmol/L), aPTT 40.0 seconds, INR—2.2, albumin 2.4 g/dL, ammonia 24.3 umol/L, estimated CrCl from the Cockcroft–Gault formula (40 mL/min)

1. *Discuss the diagnostic approach which should be taken in this patient in order to elucidate a diagnosis.*
2. *What are the top three diagnoses that could be made for this patient?*
3. *Based on your assessment of her medication history, are there any of her medications that could be potentiating her clinical condition? If so, which ones should be held or discontinued on hospital admission and transfer to the GI service?*
4. *What pharmacotherapeutic treatments should the pharmacy clinician focus on?*

PATHOPHYSIOLOGY

IAI results from bacterial entry into the peritoneal or retroperitoneal spaces or from bacterial collections within intra-abdominal organs. In primary peritonitis, bacteria may enter the abdomen via multiple mechanisms (ie, via the bloodstream or lymphatic system, by transmigration through the bowel wall, and through an indwelling PD catheter or ventriculoperitoneal catheter). **Hematogenous** bacterial spread (through the bloodstream) occurs more frequently with tuberculosis peritonitis or peritonitis associated with cirrhotic ascites. When peritonitis results from PD, skin-surface flora are introduced via the peritoneal catheter. In secondary peritonitis, bacteria most often enter the peritoneum or retroperitoneum as a result of perforation of the GI or female genital tracts caused by diseases or traumatic injuries, or via the fallopian tubes in females.

If bacteria that enter the abdomen are not contained by cellular and humoral defense mechanisms, bacterial dissemination occurs throughout the peritoneal cavity, resulting in peritonitis. This is more likely to occur in the presence of a foreign body, hematoma, necrotic tissue, large bacterial inoculum, continuing bacterial contamination, and contamination involving a mixture of synergistic organisms.

The fluid and protein shift into the abdomen (called **third spacing**) may be so dramatic that circulating blood volume is decreased, which causes decreased cardiac output and hypovolemic shock. Fluid shifts into the peritoneum occur secondary to inflammatory processes and leaky capillaries, as well as sepsis (Chapter 84). Accompanying fever, vomiting, or diarrhea may worsen the fluid imbalance. A reflex sympathetic response, manifested by sweating, tachycardia, and vasoconstriction, may be evident. With an inflamed peritoneum, bacteria and endotoxins are absorbed easily into the bloodstream (**translocation**), and this may result in septic shock (Chapter 84).[1] Other foreign substances present in the peritoneal cavity potentiate peritonitis notably feces, dead tissue, barium from medical imaging procedures, mucus, bile, and blood.

Many of the manifestations of IAIs, particularly peritonitis, result from cytokine activity. Inflammatory cytokines are produced by macrophages and neutrophils in response to bacteria and bacterial products or to tissue injury, resulting from the surgical incisions.[1] The outer membrane components of Gram-negative and Gram-positive organisms contribute to the cascade of proinflammatory cytokines, ultimately leading to end-organ dysfunction (lungs, heart, kidneys) and septic shock (Chapter 84).[6] Peritonitis may result in death because of the effects on major organ systems.

An abscess occurs if peritoneal contamination is localized but bacterial elimination is incomplete. The location of the abscess often is related to the site of primary disease. For example, abscesses resulting from appendicitis tend to appear in the right lower quadrant or the pelvis; those resulting from diverticulitis tend to appear in the left lower quadrant or pelvis. A mature abscess may have a fibrinous capsule that isolates bacteria and the liquid core from antimicrobials and immunologic defenses. In such cases, surgical drainage is the only effective therapy.

Microbiology of Intra-Abdominal Infection

KEY CONCEPT Primary bacterial peritonitis is often caused by a single organism. When peritonitis occurs in association with cirrhotic ascites, *Escherichia coli* and *Klebsiella* are isolated most frequently.[8] Other potential pathogens are *Haemophilus pneumoniae, Pseudomonas*, anaerobes, and *Streptococcus pneumoniae*.[9] Occasionally, primary peritonitis may be caused by *Mycobacterium tuberculosis*. In children, the pathogen is usually

Patient Encounter 2, Part 1

A 69-year-old man with a history of diabetes complicated by neuropathic pain, hypertension, hyperlipidemia, and ESRD on three times weekly hemodialysis presents to the dialysis center at the outpatient clinic with a 2-day history of high fevers and worsening "gut" pain. His surgical history comprises a bowel resection (5 years ago), an AV fistula graft for long-term hemodialysis plans (2 years ago). He was recently discharged from the inpatient medicine service last month with a methicillin-resistant Staphylococcus epidermidis bacteremia and GI bleed.

PMH: Diabetes with neuropathic pain, hypertension, hyperlipidemia, ESRD (oliguric)

Meds: Metformin 500 mg orally twice daily, atorvastatin 80 mg orally daily, gabapentin 300 mg orally daily, nephrocaps one capsule daily, calcium acetate 1334 mg orally daily with each meal, ferrous sulfate 325 mg orally twice daily, pantoprazole 40 mg orally daily, clonidine 0.2 mg orally three times daily, amlodipine 10 mg orally daily, valsartan 160 mg orally daily

SOC: Married, some alcohol, and no smoking, or illicit drugs

PE:

The patient is experiencing abdominal tenderness and on pain scale of 1 to 10 (endorses 7). He also had one bloody stool per rectum over the last 72 hours.

VS: T 102°F (38.9°C), BP 120/75 mm Hg, P 90 beats/min, RR 16 breaths/min, Wt 260 lb (dry weight on admission [118 kg]), Ht 6′ 4″ (193 cm)

Labs: Na 140 mEq/L (140 mmol/L), K 4 mEq/L (4 mmol/L), Cl 99 mEq/L (95 mmol/L), CO$_2$ 25 mEq/L (25 mmol/L), glucose 300 mg/dL (4.68 mmol/L), BUN 80 mg/dL (28.6 mmol/L), serum creatinine 8 mg/dL (707 μmol/L), glucose 300 mg/dL (4.68 mmol/L), total bilirubin 1 mg/dL (17.1 μmol/L), lactate 5.5 mg/dL (0.60 mmol/L), Hct 24% (0.24), Hgb 8 g/dL (80 g/L; 4.96 mmol/L), WBC 25 × 10^3/mm^3 (25 × 10^9/L), procalcitonin 10 mcg/L

1. *What test(s) or lab(s) should be done to ascertain the cause of his new possible pending hospital admission from the clinic?*
2. *Which monitoring parameters should be monitored in the next 24 to 72 hours?*
3. *What pharmacological treatments (fluids, antibiotics, and doses) and potential toxicities can occur with this initial plan?*
4. *List the top four to five most likely organisms and resistance patterns that can result from overuse of antimicrobials for intra-abdominal processes.*

S. pneumoniae or a Group A *Streptococcus, E. coli,* or *Bacteroides* species.[4,7] Peritonitis in patients undergoing PD is caused most often by common skin organisms ranging from *Staphylococcus aureus* to *Staphylococcus epidermidis*.[10]

KEY CONCEPT Because of the diverse bacteria present in the GI tract, secondary IAIs are often polymicrobial.[2,11]

Bacterial Synergism and Other Factors

A combination of aerobic and anaerobic organisms appears to increase the severity of infection (synergism). Facultative bacteria (eg, *E. coli*) may provide an environment conducive to the growth of anaerobic bacteria.[2] Although many bacteria isolated in mixed infections are nonpathogenic by themselves, their presence may be essential for the pathogenicity of the bacterial mixture.[3]

Complicating the clinical picture for treatment are polymicrobial IAIs with certain bacterial species being isolated, such as *Enterococci* or *Pseudomonas aeruginosa*. Targeting these organisms may be necessary in some patients to avoid treatment failure or mortality, especially if they are immunocompromised.[12]

CLINICAL PRESENTATION AND DIAGNOSIS

IAIs have a wide spectrum of clinical features. Patients with primary and secondary peritonitis present quite differently. Peritonitis is usually easier to detect and diagnose. Intra-abdominal abscess, on the other hand, may continue unrecognized for long periods of time because the infection is walled off and does not elicit the same host immune response as primary peritonitis.

Clinical Presentation of Primary Peritonitis

General

Patients may not be in acute distress, particularly with peritoneal dialysis (PD)-related peritonitis.

Symptoms

Patients may complain of nausea, vomiting (sometimes with diarrhea), and abdominal tenderness.

Signs

- Temperature may range from only mildly elevated to significantly elevated. In patients undergoing PD, temperature may not be elevated.
- Bowel sounds may be hypoactive.
- Cirrhotic patients may have worsening encephalopathy.
- There may be cloudy dialysate fluid with PD.

Laboratory Tests

- The WBC may range from mildly elevated to significantly elevated.
- Ascitic fluid usually contains more than 0.25 × 10^3/mm^3 (0.25 × 10^9/L) leukocytes, and bacteria may be evident on Gram stain of a centrifuged specimen.

Other Diagnostic Tests

- Culture of peritoneal dialysate or ascitic fluid should be positive.

Table 81–1

Likely Intra-Abdominal Pathogens

Type of Infection	Aerobes	Anaerobes
Primary (Spontaneous) Bacterial Peritonitis		
Children	Group A *Streptococcus, Escherichia coli*, pneumococci	—
Cirrhosis	*E. coli, Klebsiella*, pneumococci (many others)	—
Peritoneal dialysis	*Staphylococcus, Streptococcus, E. coli, Klebsiella, Pseudomonas*	—
Secondary Bacterial Peritonitis		
Gastroduodenal	*Streptococcus, E. coli*	—
Biliary tract	*E. coli, Klebsiella, Enterococci*	*Clostridium* or *Bacteroides* (infrequent)
Small or large bowel	*E. coli, Klebsiella, Proteus*	*B. fragilis* and other *Bacteroides, Clostridium*
Appendicitis	*E. coli, Pseudomonas*	*Bacteroides*
Abscesses	*E. coli, Klebsiella, Streptococcus, Enterococci*	*B. fragilis* and other *Bacteroides, Clostridium,* anaerobic cocci
Liver	*E. coli, Klebsiella, Streptococcus, Enterococci, Staphylococcus,* amoeba	*Bacteroides* (infrequent)
Spleen	*Staphylococcus, Streptococcus, E. coli, Salmonella*	

Patients with abscesses may present with symptoms that are indolent. The epidemiology and treatment of primary peritonitis are summarized in Tables 81–1 and 81–2.

PREVENTION AND TREATMENT

For patients that are presenting for elective general surgery and nonemergent surgical procedures, best practice for the prevention of IAI constitutes perioperative antimicrobial prophylaxis. Dependent on the length of the surgery, intraoperative administration of antibiotics may be required. Evidence also strongly recommends discontinuation of perioperative of antibiotics at the 24-hour time frame for antimicrobial stewardship (Chapter 69).[13] The primary goals of treatment are correction of the intra-abdominal disease processes or injuries that have caused infection and drainage of collections (**source control**) of purulent material (**abscess**). A secondary goal is to resolve the infection without major organ system complications (eg, pulmonary, hepatic, cardiovascular, or renal failure) or adverse drug effects. Ideally, the patient should be discharged from the hospital with full function for self-care and routine daily activities.

General Approach to Treatment

The treatment of IAI most often requires the coordinated use of four major modalities: (a) prompt drainage, (b) support of vital functions, (c) appropriate antimicrobial therapy to treat infection not eradicated by surgery,[14] and (d) antimicrobial stewardship principles (Chapter 69).[15,16] For most cases of primary peritonitis,

Table 81–2

Recommended Agents for the Treatment of Community-Acquired Intra-Abdominal Infections in Adults

Agents Recommended for Mild-to-Moderate Infections	Agents Recommended for High-Risk or High-Severity Infections[f]
Single Agent	
Cefoxitin[a]	Piperacillin–tazobactam
Moxifloxacin[b]	Imipenem–cilastatin[c], meropenem[c], doripenem[c]
Ertapenem[c]	
Combination Regimens	
Cefazolin[a], cefuroxime[a], ceftriaxone, cefotaxime (each in combination with metronidazole)	Cefepime, ceftazidime, ceftazidime/avibactam[d], or ceftolozane/tazobactam[e] (each in combination with metronidazole)
Ciprofloxacin[b] or levofloxacin[b] (each in combination with metronidazole)	Ciprofloxacin[b] or levofloxacin[b] (each in combination with metronidazole)

[a] Empiric first- and second-generation cephalosporin use should be avoided unless local antibiograms show > 80%–90% susceptibility of *Escherichia coli* to these agents.

[b] Use of quinolones may be associated with treatment failure due to increasing resistance of enteric pathogens including *E. coli*. Empiric quinolone use should be avoided unless local antibiograms show > 80%–90% susceptibility of *E. coli* to quinolones.

[c] Carbapenems should typically be reserved for settings where there is a high risk of resistance to other agents (ie, extended-spectrum β-lactamase [ESBL]-producing pathogens).

[d] Ceftazidime/avibactam should be reserved for patients infected with *Enterobacteriaceae* that are resistant to all other β-lactams including carbapenems, and in particular, *Klebsiella pneumoniae* carbapenemase (KPC)-producing pathogens.

[e] Ceftolozane/tazobactam should be reserved for patients infected with Gram-negative bacteria that are resistant to all other β-lactams. Ceftolozane/tazobactam may have activity against multi-drug resistant *Pseudomonas*; however, susceptibility must be confirmed.

[f] High-severity is defined as patients suffering from septic shock requiring vasopressors and intensive care unit admission.

Reproduced, with permission, from Gross AE, Olsen KM. Intra-abdominal infections. In: DiPiro JT, Yee GC, Posey M, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 11th ed. New York, NY: McGraw-Hill; 2019.

drainage procedures may not be required, and antimicrobial agents become the mainstay of therapy. Antimicrobials are an important adjunct to drainage procedures in the treatment of secondary IAIs. However, the use of antimicrobial agents without surgical intervention, especially in secondary peritonitis, is usually inadequate.

KEY CONCEPT In the early phase of serious IAIs, attention should be given to preserving major organ system function. A common cause of early death is hypovolemic shock caused by inadequate intravascular volume expansion and tissue perfusion. With generalized peritonitis, large volumes of intravenous (IV) fluids are required to maintain intravascular volume, improve cardiovascular function, and ensure adequate tissue perfusion and oxygenation. Adequate urine output should also be maintained to ensure appropriate fluid resuscitation and to preserve renal function.

An additional important component of therapy is nutrition. IAIs often involve the GI tract directly or disrupt its function (paralytic ileus). The return of GI motility may take days, weeks, and occasionally, months. In the interim, enteral or parenteral nutrition, as indicated, facilitates improved immune function and wound healing to ensure recovery.

Clinical Presentation of Secondary Peritonitis

General

Patients may be in acute distress.

Symptoms

- Patients may complain of nausea, vomiting, and generalized abdominal pain.
- Patients may demonstrate abdominal guarding and rigidity.

Signs

- Sweating, tachypnea, and tachycardia are present.
- Temperature is normal initially, then may increase to 100 to 102°F (37.8–38.9°C) within the first few hours; temperature may continue to rise for the next several hours.
- Hypotension and shock may develop if intravascular volume is not restored.
- Decreased urine output may develop secondary to dehydration or intravascular volume depletion.
- Bowel sounds are faint initially and eventually cease.

Laboratory Tests

- The WBC count is typically high (WBCs 15–20 × 10^3/mm^3 [15–20 × 10^9/L]), with neutrophils predominating and an elevated percentage of immature neutrophils (bands).
- The hematocrit and blood urea nitrogen increase because of dehydration.
- Hyperventilation and vomiting result in early alkalosis, which changes to acidosis and lactic academia due to reduced intravascular volume and diminished tissue perfusion.

Other Diagnostic Tests

Abdominal radiographs may be useful because free air in the abdomen (indicating intestinal perforation) or distension of the small or large bowel is often evident.

Nonpharmacologic Therapy

▶ Drainage Procedures

Primary peritonitis is treated with antimicrobials and rarely requires drainage. Secondary peritonitis requires surgical removal of the inflamed or gangrenous tissue to prevent further bacterial contamination. If the surgical procedure is suboptimal, attempts are made to provide drainage of the infected or gangrenous structures.

The drainage of purulent material is the critical component of management of an intra-abdominal abscess. This may be performed surgically or with percutaneous image-guided techniques.[16] Without adequate drainage of the abscess, antimicrobial therapy and fluid resuscitation can be expected to fail. In addition, some of the most valuable microbiologic information may be obtained at the time of percutaneous or operative abscess drainage.

▶ Fluid Therapy

In patients with peritonitis, hypovolemia is often accompanied by acidosis, and large volumes of a balanced crystalloid IV solution, such as Lactated Ringer's, may be required initially to restore intravascular volume. Maintenance fluids should be instituted (after intravascular volume is restored) with 0.9% sodium chloride and potassium chloride (20 mEq/L [20 mmol/L]) or 5% dextrose and 0.45% sodium chloride with potassium chloride (20 mEq/L [20 mmol/L]). The administration rate should be based on estimated daily fluid loss through urine and nasogastric suction, including 0.5 to 1.0 L for insensible fluid loss. Aggressive fluid therapy often must be continued in the postoperative period because fluid will continue to sequester in the peritoneal cavity, bowel wall, and lumen.

Pharmacologic Therapy

▶ Antimicrobial Therapy

The goals of antimicrobial therapy are as follows:

- To control bacteremia and prevent the establishment of metastatic foci of infection
- To reduce suppurative complications after bacterial contamination
- To prevent local spread of existing infection
- To de-escalate antimicrobials as soon as pathogens are identified and culture and sensitivity data are reported

KEY CONCEPT An empirical antimicrobial regimen should be started as soon as the presence of IAI is suspected and before identification of the infecting organisms is complete. Therapy must be initiated based on the likely pathogens, which vary depending on the site of IAI, the underlying disease process, and individual history of previous organisms. Cultures of metastatic IAI sites generally are not useful for directing antimicrobial therapy. Table 81–1 lists the likely pathogens against which antimicrobial agents should be directed.

▶ Antimicrobial Experience

Important findings from clinical trials regarding selection of antimicrobials for IAIs are as follows:

- Antimicrobial regimens for secondary IAIs should cover a broad spectrum of aerobic and anaerobic bacteria from the GI tract. It is believed that the overuse of antimicrobials has contributed to the development of IAIs with carbapenem-resistant *Enterobacteriaceae* (CRE), *Pseudomonas*, and

Patient Encounter 1, Part 2: Physical Examination and Diagnostic Tests

PE:

The patient is experiencing more pain (8/10 pain scale), and the attending physician decides to perform an invasive test.

Ascitic fluid analysis is reported as follows: hazy yellow color with 3225/mm^3 (3.225 × 10^9/L) WBC, (40% [0.40] neutrophils, 5% [0.05] lymphocytes, 55% [0.55] macrophages). Urinalysis is not significant because the patient is oliguric. Other physical examination findings are nonsignificant.

VS: As noted previously

Labs: As noted previously

Serum: As noted previously

KUB: Negative findings

DPL (diagnostic peritoneal lavage): 3225/mm^3 (3225 × 10^9/L)

Microbiological cultures: 2/2 bottles from the blood positive for Gram-positive pairs in chains and Gram-negative bacilli.

1. *Discuss the most appropriate pharmacologic course of treatment, outlining medications, dosing, and monitoring parameters.*
2. *List the goals of treatment and follow-up plan that should be developed by the clinician to ensure positive patient outcomes.*

PE:

The patient is becoming more obtunded 24 hours into the hospital course, so it is difficult to determine her degree of pain. The attending physician decides to perform an invasive test(s).

Ascitic fluid analysis is reported as follows: moderate bloody turbid color with 1,036/mm^3 (1.036 × 10^9/L) WBC, (44% [0.44] neutrophils, 5% [0.05] mesothelial cells, 51% [0.51] macrophages), RBC 19,182/mm^3 ANC 456 units/mm^3. Other physical examination findings are nonsignificant, except for asterixis (similar to initial presentation).

VS: As noted previously

Labs: As noted previously

Serum: As noted previously

KUB: Distended loops of bowel

DPL (diagnostic peritoneal lavage): WBC 1,036/mm^3 (1.036 × 10^9/L), RBC 19,182/mm^3 (19,182 × 10^9)

Microbiological cultures: 2/2 bottles from the blood are positive for Gram-negative bacilli.

1. *Discuss the most appropriate pharmacologic course of treatment, outlining medications, dosing, and monitoring parameters.*
2. *List the goals of treatment and follow-up plan that should be developed by the clinician to ensure positive patient outcomes.*
3. *Based on the fact that this patient speaks Russian, how can the pharmacist on the multidisciplinary team bridge the gaps of educating the patient on their diagnosis, medical/surgical care, and medication education?*

Acinetobacter spp., as well as greater prevalence of methicillin-resistant *S. aureus* (MRSA), *Candida* spp., and *Enterococcus* IAIs. This has made drug selection a challenge.[18,19]

Patient Encounter 2, Part 2

The patient's clinical status worsens over the next 24 hours requiring the patient to be intubated with high Fi02 requirements; vasopressors being initiated (norepinephrine and vasopressin); 2 L of Lactated Ringer's being administered; and stat antimicrobial coverage being initiated. Neurologically, the patient is more obtunded and has a Richmond Agitation Sedation Score (RASS) of −5 indicating near coma (despite no sedation or analgesia post intubation).

1. *What are your next steps in terms of a care plan as well as monitoring parameters for this patient?*
2. *If the patient's blood cultures (2/2 bottles) reveal both a Pseudomonas aeruginosa and Enterococcus spp., what new agents could be used and what treatment duration should you use?*
3. *If this is an intra-abdominal infectious process, what should be the nonpharmacological treatment plan and goals and the pharmacological plans and goals for this patient?*

- Single-agent regimens (such as antianaerobic cephalosporins, extended-spectrum penicillins with β-lactamase inhibitors, or carbapenems) are as effective with fewer adverse effects as combinations of aminoglycosides (more adverse reactions) or fluoroquinolones (more incidences of *Clostridium difficile*) with antianaerobic agents. This is also true for antimicrobial treatment of acute bacterial contamination from penetrating abdominal trauma.
- Antimicrobial stewardship efforts in the treatment of IAIs show promise to curb antimicrobial overuse that contributes to multidrug-resistant (MDR) organisms, without affecting positive outcomes.[20] Strategies utilized by antimicrobial stewardship programs (ASPs) are impactful on antimicrobial use when they incorporate institution-specific antibiograms, utilize national guidelines for treatment, and proactively target adherence with education to prescribers for IAIs (Chapter 69).[18]
- Metronidazole in combination with either certain cephalosporins or fluoroquinolones (ciprofloxacin, levofloxacin) is considered effective empiric antimicrobial regimens for mild–moderate infections and high-risk or high-severity infections.
- Oral alternatives (such as moxifloxacin; the combination of levofloxacin or ciprofloxacin plus metronidazole; or amoxicillin-clavulanate) can be considered if patients can be transitioned. (after susceptibility results and clinical improvements are noted).

- Results from recent trials suggest that a 4-day duration of therapy is acceptable for most patients with IAIs with adequate source control.[21,22]
- New agents for the treatment of MDR Gram-negative bacilli for complicated IAIs have recently been approved. Ceftolozane is a novel cephalosporin with the β-lactamase inhibitor tazobactam that confers enhanced activity against both *P. aeruginosa* and MDR Gram-negative bacilli. Ceftazidime–avibactam is another combination antibiotic (β-lactam/β-lactamase inhibitor) and treatment option in complicated IAIs (*Klebsiella pneumoniae* CRE). Both new antibiotics have been studied in combination with metronidazole. Another new broad spectrum fluorocycline antibiotic, eravacycline, is approved for complicated IAIs, specifically due to CRE bacteria but lacks *P. aeruginosa* coverage.[23] ASPs will need to ensure proper use of these agents to limit resistance as much as possible.[24-28]
- IAIs present in many different ways and with a wide spectrum of severity. The antibiotic regimen employed and the duration of treatment depend on the specific clinical circumstances (ie, the nature of the underlying disease process and the condition of the patient).

Recommendations

KEY CONCEPT For most IAIs, the antimicrobial regimen should be effective against both aerobic and anaerobic bacteria.[16] Although it is impossible to provide antimicrobial activity against every possible pathogen, agents with activity against enteric Gram-negative bacilli, such as *E. coli* and *Klebsiella* spp., and anaerobes, such as *Bacteroides fragilis* and *Clostridia* spp., should be administered.

Table 81–2 presents the recommended agents for treatment of community-acquired and complicated IAIs from the Infectious Diseases Society of America and the Surgical Infection Society.[29] These recommendations were formulated using an evidence-based approach. Most community-acquired infections are "mild-to-moderate," whereas healthcare-associated infections tend to be more severe and difficult to treat. Table 81–3 presents guidelines for treatment and alternative regimens for specific situations. These are general guidelines; there are many factors that cannot be incorporated into such a table.

Aminoglycosides (with nephrotoxicity and ototoxicity being a concern) and clindamycin have been relegated to secondary or tertiary options for the treatment of IAIs. Metronidazole is the agent of choice for *B. fragilis*; but antianaerobic cephalosporins, such as cefoxitin, cefotetan, or ceftizoxime, and combinations of extended-spectrum penicillins with β-lactamase inhibitors would be suitable alternatives. Preemptive antifungal therapy may be indicated with either an azole antifungal (fluconazole) or an echinocandin (caspofungin or micafungin) in patients who are immunocompromised or postsurgical with recurrent infection. These patients are more likely to develop a fungus secondary to risk factors such as being on broad-spectrum antimicrobials, having central lines, and being on parenteral nutrition.

In immunocompromised patients or patients with valvular heart disease or a prosthetic heart valve, there is justification to provide specific antimicrobial activity against *Enterococci*. Ampicillin or other penicillins are active against *Enterococci* (eg, penicillin and piperacillin) and should be used in patients at high risk of IAI, patients with persistent or recurrent IAI, or patients who are immunosuppressed, such as after organ transplantation. Ampicillin remains the drug of choice for this indication because it is most active in vitro against *Enterococci* and is relatively inexpensive. Vancomycin is active against most *Enterococci*; however, resistance is increasing.

Intraperitoneal (IP) administration of antibiotics is preferred over IV therapy in the treatment of peritonitis that occurs in patients undergoing CAPD.[30] The International Society of Peritoneal Dialysis guidelines for the diagnosis and pharmacotherapy of PD-associated infections provide dosing recommendations for intermittent and continuous therapy based on the modality of dialysis (CAPD or automated peritoneal dialysis [APD]) and the extent of the patient's residual renal function.[10]

KEY CONCEPT Antimicrobial agents effective against both Gram-positive and Gram-negative organisms should be used for initial IP empirical therapy for peritonitis in PD patients. The most important factors to take into consideration for initial antimicrobial selection are the dialysis center's and the patient's history of infecting organisms and their susceptibilities. The use of cefazolin (loading dose [LD] 500 mg/L, maintenance dose [MD] 125 mg/L) plus ceftazidime (LD 500 mg/L, MD 125 mg/L) or cefepime (LD 250–500 mg/L, MD 100–125 mg/L) or gentamicin (LD 8 mg/L, MD 4 mg/L) or tobramycin (LD 3 mg/kg, MD 0.3 mg/kg) is suitable for initial two-drug combination empirical therapy. If patients are allergic to cephalosporin antibiotics, vancomycin (LD 30 mg/kg, MD 1.5 mg/kg/bag) or an aminoglycoside should be substituted. Aztreonam (LD 1000 mg/L, MD 250 mg/L) is an alternative to ceftazidime or cefepime in this patient population. Another option is monotherapy with imipenem–cilastatin (LD 250 mg/L, MD 50 mg/L) or cefepime. Antimicrobial doses should be increased empirically by 25% in patients with residual renal function (> 100 mL/day urine output).[10] Repeat dialysis effluent cell counts and cultures should be done after at least 3 to 5 days of antimicrobial therapy, which should continue for at least a 14- to 28-day treatment course dependent on the microorganism identified. The reader is referred to these guidelines for additional information.[10]

After acute bacterial contamination, such as with abdominal trauma where GI contents contaminate the peritoneum, combination antimicrobial regimens are not required. If the patient is seen soon after injury (within 2 hours) and surgical measures are instituted promptly, antianaerobic cephalosporins (eg, cefoxitin or cefotetan) or extended-spectrum penicillins are effective in preventing most infectious complications. Antimicrobials should be administered as soon as possible after injury.[30]

For appendicitis, the antimicrobial regimen used should depend on the appearance of the appendix at the time of operation, which may be normal, inflamed, gangrenous, or perforated. Because the condition of the appendix is unknown preoperatively, it is advisable to begin antimicrobial agents before the appendectomy is performed. Reasonable regimens would be antianaerobic cephalosporins or, if the patient is seriously ill and on vasopressors in the intensive care unit (Chapter 84), a carbapenem or β-lactam–β-lactamase-inhibitor combination that are more broad spectrum in their scope. If, at operation, the appendix were normal or inflamed, postoperative antimicrobials would not be required. If the appendix is gangrenous or perforated, a treatment course of 4 days with the agents listed in Table 81–2 is appropriate.

KEY CONCEPT Acute intra-abdominal contamination, such as after a traumatic injury, may be treated with a short course (24 hours) of antimicrobials if therapy is begun quickly.[29] For established infections (ie, peritonitis or intra-abdominal abscess), an antimicrobial course limited to 4 days is justified. Under certain

Table 81–3

Guidelines for Empiric Antimicrobial Agents for Intra-Abdominal Infections[10,29]

	Primary Agents	Alternatives
Primary (Spontaneous) Bacterial Peritonitis		
Cirrhosis	Ceftriaxone, cefotaxime	1. Piperacillin–tazobactam, carbapenems 2. Aztreonam combined with an agent active against *Streptococcus* spp. (eg, vancomycin) or quinolones with significant *Streptococcus* spp. activity (levofloxacin, moxifloxacin)
Peritoneal dialysis	Initial empiric regimens should be active against both Gram-positive (including *Staphylococcus aureus*) and Gram-negative pathogens: Gram-positive agent (first-generation cephalosporin or vancomycin) plus a Gram-negative agent (third-generation cephalosporin or aminoglycoside)	1. Cefepime or carbapenems may be used alone 2. Aztreonam or an aminoglycoside may be used in place of ceftazidime or cefepime as long as combined with a Gram-positive agent 3. Quinolones may be used in place of Gram-negative agents if local susceptibilities allow
	1. *Staphylococcus* spp.: oxacillin/nafcillin or first-generation cephalosporin	1. Vancomycin should be used if concern for methicillin-resistant *Staphylococcus* spp. 2. Add rifampin for 5–7 days with vancomycin to reduce the risk for relapsing or repeat methicillin-resistant *S. aureus* peritonitis
	2. *Streptococcus* or *Enterococcus*: ampicillin	1. An aminoglycoside may be added for *Enterococcus* spp. 2. Linezolid, daptomycin, or quinupristin/dalfopristin should be used to treat vancomycin-resistant *Enterococcus* spp. not susceptible to ampicillin.
	3. Aerobic Gram-negative bacilli: ceftazidime or cefepime	1. The regimen should be based on in vitro sensitivity tests.
	4. *Pseudomonas aeruginosa*: two agents with differing mechanisms of action, such as an oral quinolone plus ceftazidime, cefepime, gentamicin, or a carbapenem	
Secondary Bacterial Peritonitis		
Perforated peptic ulcer	First-generation cephalosporins	1. Ceftriaxone, cefotaxime, or antianaerobic cephalosporins[a]
Other	Third- or fourth-generation cephalosporin with metronidazole, piperacillin–tazobactam or carbapenem	1. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole, or moxifloxacin[b] alone 2. Aztreonam with vancomycin and metronidazole 3. Antianaerobic cephalosporins[a]
Abscess		
General	Third- or fourth-generation cephalosporin with metronidazole, piperacillin–tazobactam	1. Imipenem-cilastatin, meropenem, doripenem, or ertapenem 2. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or moxifloxacin alone
Liver	As above	Use metronidazole if amoebic liver abscess is suspected
Spleen	Ceftriaxone or cefotaxime	Moxifloxacin[b] or levofloxacin[b]
Other Intra-Abdominal Infections		
Appendicitis	Same management as for community-acquired complicated intra-abdominal infections as listed in Table 81–2	
Community-Acquired Acute Cholecystitis	Ceftriaxone or cefotaxime	Severe infection, piperacillin/tazobactam, antipseudomonal carbapenem, aztreonam with metronidazole
Cholangitis	Ceftriaxone or cefotaxime each with or without metronidazole	Vancomycin with aztreonam with or without metronidazole
Acute Contamination from Abdominal Trauma	Anti-anaerobic cephalosporins[a] or metronidazole with either ceftriaxone or cefotaxime	1. Piperacillin/tazobactam or a carbapenem 2. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or moxifloxacin alone

[a] Cefoxitin or cefotetan; these agents should be avoided empirically unless local antibiograms show > 80%–90% susceptibility of *Escherichia coli* to these agents.

[b] Use of quinolones may be associated with treatment failure due to increasing resistance of enteric pathogens including *E. coli*. Empiric quinolone use should be avoided unless local antibiograms show > 80%–90% susceptibility of *E. coli* to quinolones.

conditions, therapy for longer than 4 days would be justified (eg, poor response, resistant organism identified, or failure to control the source of infection). For some abscesses, such as pyogenic liver abscess, antimicrobials may be required for a month or longer because of resistance increasing after initial antimicrobial treatment.

OUTCOME EVALUATION

Whether diagnosed with primary or secondary peritonitis, monitor the patient for relief of symptoms. Once antimicrobials are initiated, and the other important therapies described earlier are used, most patients should improve within 2 to 3 days. Successful antimicrobial therapy with resolution of infection will result in decreased pain, manifested as resolution of abdominal guarding and decreased use of pain medications over time. The patient should not appear in distress, with the exception of recognized discomfort and pain from incisions, drains, and a nasogastric tube.

Monitor vital signs and WBC count with differential; each should normalize as the infection resolves. At 24 to 48 hours, aerobic bacterial culture results should be available. If a suspected pathogen is not susceptible to the antimicrobial agents being given, and the patient has not sufficiently improved, the regimen should be adjusted. If the isolated pathogen is susceptible to one antimicrobial and the patient is improving, therapy should be streamlined to a single agent.

With anaerobic culturing techniques and the slow growth of these organisms, anaerobes often are not identified until 4 to 7 days after culture, and sensitivity information is difficult to obtain. For this reason, anaerobic culture information generally is not helpful for selection of the antianaerobic component of the antimicrobial regimen.

Once the patient's temperature is normal for 48 to 72 hours, and the patient is eating, consider changing the IV antibiotic to an oral regimen for the duration of antibiotic treatment. Monitor the serum creatinine level to evaluate for renal complications as well as potential drug toxicity. Bowel sounds should return to normal. Evaluate the patient daily for development of rash or other drug-related adverse effects such as antibiotic-associated diarrhea.

For patients with primary peritonitis, if peritoneal dialysate cultures were positive initially, repeat cultures should be negative. For patients with secondary peritonitis, monitor the amount of fluid draining if a drain was placed. The volume of drainage should lessen as the infection resolves. Repeat abdominal radiographs should return to normal.

If symptoms do not improve, the patient should be evaluated for persistent infection. There are many reasons for poor patient outcome with IAI; improper antimicrobial selection is only one. The patient may be immunocompromised, which decreases the likelihood of successful outcome with any regimen. It is impossible for antimicrobials to completely compensate for a nonfunctioning immune system. There may be surgical reasons for poor patient outcome. Failure to identify all intra-abdominal foci of infection or leaks from a GI anastomosis may cause continued IAI. Even when IAI is controlled, accompanying organ system failure, most often renal or respiratory, may lead to patient demise.

KEY CONCEPT Healthcare–associated infections are becoming more commonly seen for IAIs with increasing prevalence of acute care hospital admissions or admissions from chronic care settings. The major pathogens include more resistant Gram-negative flora, *Candida* infections causing peritonitis, and *Enterococcus* species.[31]

The outcome from IAI is not determined solely by what transpires in the abdomen. Unsatisfactory outcomes in patients with IAIs may result from complications that arise in other organ systems. Infectious complications commonly associated with mortality after IAI are urinary tract infections and pneumonia.[19] Reasons for antimicrobial failure may not always be apparent. Even when antimicrobial susceptibility tests indicate that an organism is susceptible to the antimicrobial agent, therapeutic failures may occur. There may be poor penetration of the antimicrobial agent into the focus of infection, or bacterial resistance may develop after initiation of antimicrobial therapy. Superinfection—a secondary infection resulting from the preferential killing of the primary pathogen—can be caused by *Candida*; however, *Enterococci* or opportunistic Gram-negative bacilli such as *Pseudomonas* or ESBL-producing *Enterobacteriaceae* may also be involved.

Treatment regimens for IAI can be deemed successful if the patient recovers from the infection without recurrent peritonitis or intra-abdominal abscess and without the need for additional antimicrobials. A regimen can be considered unsuccessful if a patient

Patient Care Process

Collect Information:

- You should do a thorough patient medication history at the time of admission to document all recent medication use, including nonprescription medications and the use of complementary or alternative medicines. You should also document any drug allergies or intolerances for your patient. You should also search for all available patient information in the pertinent patient's medical record.

Assess the Information:

- Be cognizant for the initial antimicrobial regimen conforming to standard guidelines (unless an appropriate justification for an alternative regimen is evident).

Develop a Care Plan:

- You should review the dosages of all medications to be sure that they are appropriate for age, weight, and major organ function.
- You should also verify that the drugs selected are not contraindicated in the patient with allergies or drug–drug interactions.

Implement the Care Plan:

- You should select antimicrobials that are appropriate based on the susceptibility information, while reviewing the results of the cultures obtained both preoperatively or during the surgical procedure. Antimicrobials should be de-escalated when clinically appropriate. You should educate other practitioners on proper de-escalation technique.
- On the second or third day of antimicrobial treatment or when GI function returns, determine whether parenteral antimicrobial agents can be switched to oral agents to complete therapy. This again is part of a robust ASP best practice.
- Assess nutritional needs and recommend appropriate supplementation. When the patient is tolerating an oral diet, determine whether any parenteral medications can be switched to the oral route.

Follow-up: Monitor and Evaluate:

- You should monitor the patient for the development of potential complications of treatment such as delayed hypersensitivity reactions, antibiotic-induced diarrhea, pseudomembranous colitis, or fungal superinfections (eg, oral thrush).
- You should also educate the patient on the medications administered in the hospital as well as any new medications prescribed for use at home.
- You should also advise the patient to contact his or her doctor or pharmacist if he or she experiences any adverse effects from medications.

develops a tertiary peritonitis (ie, the need for reoperation or percutaneous drainage is necessary or if improvement is delayed beyond 1 or 2 weeks) or if a significant adverse drug reaction occurs.

Abbreviations Introduced in This Chapter

APD	Automated peritoneal dialysis
ASP	Antimicrobial stewardship program
CAPD	Continuous ambulatory peritoneal dialysis
CRE	Carbapenemase-resistant *Enterobacteriaceae*
DPL	Diagnostic peritoneal lavage
ESBL	Extended-spectrum producing β-lactamase *Enterobacteriaceae*
IAIs	Intra-abdominal infections
IP	Intraperitoneal
KPC	*Klebsiella* pneumonia carbapenemase
LD	Loading dose
MD	Maintenance dose
MDR	Multidrug-resistant
MRSA	Methicillin-resistant *S. aureus*
PD	Peritoneal dialysis

Urinary Tract Infections and Prostatitis

Spencer H. Durham

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Determine the diagnostic criteria for significant bacteriuria, urinary tract infections (UTIs), and catheter-associated UTIs.
2. Recognize the signs and symptoms of UTIs, and differentiate asympotomatic bacteriuria from acute cystitis and pyelonephritis and acute prostatitis from chronic prostatitis.
3. Identify the pathogenic organisms most commonly implicated in different UTIs.
4. Assess the laboratory tests used in the diagnosis of UTIs.
5. Based on clinical signs, symptoms, and laboratory parameters, recommend appropriate empiric and targeted pharmacotherapy for the treatment of acute cystitis, pyelonephritis, and prostatitis, including drug, dose, and duration of therapy.
6. Formulate appropriate monitoring and education information for patients with UTIs.

INTRODUCTION

A urinary tract infection (UTI) is defined as the presence of pathogenic microorganisms in the genitourinary tract with associated signs and symptoms of infection. UTIs represent a diverse array of syndromes based on location within the urinary tract, including acute cystitis, pyelonephritis, and prostatitis.[1-3] UTIs are one of the most common reasons for the receipt of antimicrobial therapy.[4]

EPIDEMIOLOGY AND ETIOLOGY

The prevalence and type of UTIs generally vary according to age and gender.[5,6] In adults, bacteriuria is more common in young, nonpregnant women (range, 1%–3%) but uncommon in men (up to 0.1%).[7] Symptomatic UTIs occur most frequently in women of childbearing age. It is estimated that the lifetime risk of UTIs in women is as high as 60%, with 25% of those patients experiencing a recurrence within 1 year.[8] UTIs are much more common in women than men due to their inherently shorter urethra and proximity to the perineal area. However, older men may experience UTIs due to immunoscenesence and concomitant disease states, such as benign prostatic hypertrophy (BPH).

KEY CONCEPT UTIs are classified as either uncomplicated or complicated. Uncomplicated infections usually occur in women of childbearing age. Complicated UTIs usually occur in patients who have structural or functional abnormalities of the genitourinary tract and may involve the bladder or the kidneys.[2] UTIs in male patients and mostly older adults are considered complicated. Although complicated infections are usually treated similar to uncomplicated infections, a longer treatment duration is typically warranted in complicated infections. UTIs can also be classified as upper and lower depending on their anatomical location. Lower UTIs usually refer to acute cystitis, whereas upper UTIs refer to pyelonephritis. It is important to note that an upper UTI does not necessarily imply complicated UTI, nor does a lower UTI imply uncomplicated UTI.

The etiologic pathogens of most UTIs originate from the perirectal area. *Escherichia coli* is implicated in more than 80% of uncomplicated infections, with *Klebsiella pneumoniae* and *Proteus* species being less common.[9] Gram-positive organisms, such as *Staphylococcus saprophyticus* and *Enterococcus* species, are uncommon but potential causes.[10,11] Although *E. coli* is still implicated in complicated UTIs, it causes less than 50% of these infections. The bacteria responsible for complicated infections are generally more varied than with uncomplicated infections, and some complicated infections may be due to highly resistant organisms such as *Enterobacter* species and *Pseudomonas aeruginosa*.[12]

PATHOPHYSIOLOGY

There are three potential pathways for bacteria to enter the urinary tract and cause infection: the ascending, hematogenous, and lymphatic pathways. The most common route of infection is via the ascending pathway. **KEY CONCEPT** Due to the inherently short urethra and proximity to the perirectal area, bacteria often colonize the female urethra. The ascending pathway of infection involves ascension of colonized bacteria upward into the bladder, leading to acute cystitis[13] (Figure 82–1). Once in the bladder, bacteria may continue to ascend the urinary tract via the ureters and cause upper UTIs as well.

The hematogenous route involves the seeding of the urinary tract with pathogens carried through the blood from a distant site of infection. For example, *Staphylococcus aureus* bacteremia is known to cause UTIs and renal abscesses via the hematogenous route.[14] However, less than 5% of all UTIs are thought to be related to hematogenous spread. The lymphatic pathway is least understood because it is uncertain that bacterial transmission occurs in this manner.

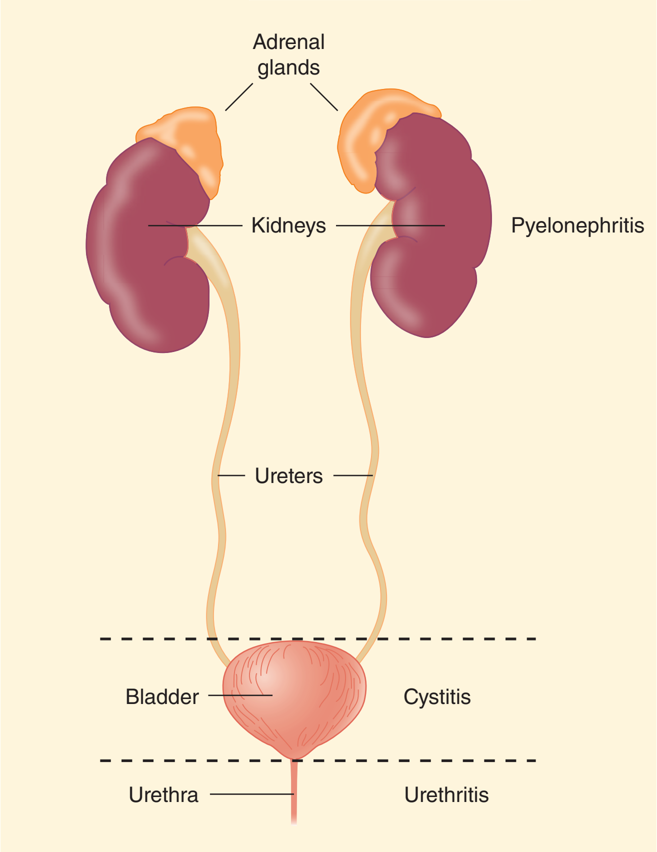

FIGURE 82–1. Anatomy and associated infection of the urinary tract. (From Sprandel KA, Lesch CA, Rodvold KA. Lower urinary tract infection. In: Schwinghammer TL, ed. 6th ed. New York, NY: McGraw-Hill; 2005:315; with permission.)

Host Defense Mechanisms and Risk Factors

Urine possesses numerous characteristics unsuitable for bacterial metabolism and growth, such as low pH, high urea concentration, and high osmolality. The presence of bacteria in the bladder stimulates an urge to urinate to void the bladder and release the bacteria. In addition, innate host response and adaptive immunity are defense mechanisms against bacterial infections, including UTIs.[15]

There are several risk factors for development of UTIs.[7] Common risk factors for uncomplicated infections in women include sexual intercourse, use of a cervical diaphragm or spermicidal jellies, diabetes, and pregnancy.[16-18] Risk factors in men include not being circumcised and, in older men, prostatic hyperplasia. In complicated infections, urinary tract obstruction is a common risk factor for both men and women. Vesicouretal reflux (VUR), which can result from obstruction or congenital abnormalities, results in urine being forced from the ureters into the kidneys, which can also predispose to infection.[19,20] Other risk factors common to both men and women include urologic instrumentation, urethral catheterization, renal transplantation, and neurogenic bladder.[21,22]

CLINICAL PRESENTATION AND DIAGNOSIS

Signs and symptoms of lower UTIs include increased urinary frequency, urgency, dysuria, nocturia, and suprapubic heaviness. Systemic signs and symptoms are uncommon with lower UTIs. By contrast, patients with pyelonephritis often present with systemic signs and symptoms, such as fever, chills, flank pain, nausea and vomiting, and elevated white blood cell count. Older adults often do not present with traditional signs and symptoms of a UTI due to the naturally impaired ability of their immune systems to mount a typical response to infections. Instead, they may experience altered mental status, poor appetite, and incontinence. While older adults often experience altered mental status, it is a nonspecific symptom, and other causes should also be considered when assessing for the presence of a UTI; altered mental status alone is not an indication for empiric treatment with antimicrobials.

The diagnosis of a UTI should generally be based on signs and symptoms in conjunction with laboratory tests to determine bacterial counts in the urine. Bacteriuria, defined as the presence of bacteria in the urine, does not always represent true infection. Asymptomatic bacteriuria (ASB) is the isolation of a quantitative amount of bacteria from an appropriately collected urine specimen in a patient without signs and symptoms of a UTI.[2] While a full discussion of ASB is beyond the scope of this chapter, it is important to note that it should only be treated with antimicrobial therapy in very selected circumstances (eg, pregnancy and endoscopic urological procedures associated with mucosal trauma) and not in premenopausal, nonpregnant women. To help diagnose true UTIs, quantitative diagnostic criteria have been developed based on the number of bacteria present in the urine combined with the presence or absence of infectious signs and symptoms (Table 82–1). A urinalysis is a microscopic examination of the urine and can be helpful to aid in diagnosis. Common abnormalities associated with UTIs seen on urinalysis can be seen in the clinical presentation and diagnosis of UTIs textbox. In particular, the presence of white blood cells (pyuria) and leukocyte esterase (by-products of white blood cells) will almost always be seen in patients with UTIs. In addition, the presence of nitrite-sis usually associated with infection. Nitrates are normally found in the urine, but some Gram-negative organisms, such as *E. coli*, *Klebsiella pnuemoniae*, and *Proteus mirabilis*, reduce nitrates into nitrites. A urine culture, which can identify the quantity of bacteria in the urine and the specific infecting organism, is considered the gold standard for confirmatory diagnosis of a UTI in symptomatic patients.

Table 82–1

Quantitative Diagnostic Criteria for UTIs

Condition	Quantitative Measure
Asymptomatic bacteriuria	• Two consecutive urine cultures with the same organism ≥ to 10^5 CFU/mL in asymptomatic patients
UTI	• ≥ 10^5 CFU/mL in a symptomatic woman[a] • ≥ 10^3 CFU/mL in a symptomatic man • Any growth of bacteria on suprapubic catheterization in a symptomatic patient
Catheter-associated UTI	• ≥ 10^3 CFU/mL of at least one pathogenic species in a symptomatic patient • ≥ 10^5 CFU/mL of at least one pathogenic species in any patient regardless of symptoms

[a] Some women may have signs and symptoms of a UTI but less organisms on culture results. Treatment is still indicated for these patients.

CFU, colony-forming unit; UTI, urinary tract infection.

Clinical Presentation and Diagnosis of UTIs

General

- Most otherwise healthy women present with local signs and symptoms, such as dysuria and increased urgency and frequency.
- Patients with lower UTIs rarely present with systemic signs and symptoms, whereas those with upper UTIs usually do.
- Older adults (≥ 65 years) are often asymptomatic or present with altered mental status.
- More than 95% of uncomplicated UTIs are caused by a single organism, most commonly *Escherichia coli*.

KEY CONCEPT Signs and Symptoms of Lower UTIs

- Dysuria, gross hematuria, suprapubic heaviness, nocturia, increased urinary frequency, and urgency

KEY CONCEPT Signs and Symptoms of Upper UTIs

- Fever, chills, nausea/vomiting, malaise, and flank pain

Laboratory Tests

Urinalysis abnormalities include:

- **Pyuria** typically greater than 10 white blood cells/mm^3 urine (10×10^6/L)
- Bacteriuria, usually greater than 10^5 CFU organisms/mL (10^8 CFU/L)
- Presence of nitrites
- Presence of leukocyte esterase
- Bacterial urine culture
- Gold standard for diagnosis in a symptomatic patient

Patient Encounter Part 1

JK is a 43-year-old woman who presents to her primary care physician complaining of a 3-day history of burning upon urination and having to urinate frequently throughout the day and during the night. She reports she "felt hot" at home but did not take her temperature, and she began experiencing mild flank pain today, which she reports as the reason for the physician visit. She denies vomiting and nausea. Her medical history is significant for depression, which is well-controlled with fluoxetine. The physician orders a urinalysis to be performed in the office.

What signs and symptoms are suggestive of a urinary tract infection (UTI)?

Would you classify this patient as uncomplicated or complicated UTI?

Would you classify this infection as a lower or upper UTI?

What additional patient information is required before creating an appropriate treatment plan for this patient?

TREATMENT

KEY CONCEPT The goals of treatment are to eradicate the causative pathogen, prevent or treat consequences of infection, administer appropriate empiric antimicrobial therapy or targeted therapy based on culture results, and prevent recurrence of infection.

Antimicrobial therapy is the cornerstone of treatment in symptomatic UTIs. Ideally, the selected antimicrobial should be well tolerated, be active against the most likely pathogenic organisms, require few total doses, achieve adequate concentrations in the urinary tract, possess few drug interactions, have a wide therapeutic index, and have good oral bioavailability. In addition, the empiric antimicrobial should be sufficiently narrow in antimicrobial spectrum to be unlikely to cause collateral damage (the ecological adverse effects of antimicrobial therapy).[1]

Nonpharmacologic Therapy

Several nonpharmacologic therapies have been proposed for prevention of UTIs with varying degrees of supportive evidence. Large volumes of cranberry juice have been associated with a decrease in the number of recurrent UTIs over a year period in small, randomized controlled trials, but efficacy is uncertain in the general population and with smaller intake volumes.[23-25] Probiotics such as *Lactobacillus* spp. lower urinary pH and may reduce the growth of pathogenic bacteria and show promise in preventing recurrent UTIs in women.[26] Although uncommonly used, topical estrogen replacement therapy has been shown to significantly decrease the incidence of UTIs in postmenopausal women as compared with placebo.[27] Methenamine hippurate and methenamine mandelate are hydrolyzed in acidic urine to the antimicrobial formaldehyde and effective in preventing UTIs in patients without renal tract abnormalities.[28] Although several of these therapies show promise in the treatment of UTIs, their roles in therapy are currently unclear due to overall limited evidence.

Pharmacologic Therapy

Table 82–2 reviews oral and intravenous (IV) antibiotics frequently used to treat UTIs with comments on their use, and Table 82–3 reviews frequency, duration, and doses of oral antibiotics used commonly for outpatient treatment of UTIs.

▶ *Uncomplicated UTIs*

Cystitis Because patients with uncomplicated acute cystitis rarely manifest systemic signs and symptoms of infection, treatment is generally provided in the outpatient setting.[1] Patients are subsequently monitored for resolution of signs and symptoms. **KEY CONCEPT** Uncomplicated UTIs are usually managed with a short-course antimicrobial therapy involving one-dose, 3-day, or 5-day regimens depending on the clinical factors involved. Because urine culture results take several days for complete results, empiric treatment in the outpatient setting will often be complete prior to obtaining final culture results. Therefore, urine cultures are rarely obtained.[1,29]

For acute uncomplicated UTIs, there are three primary oral empiric treatment options: one dose of fosfomycin, a 3-day course of trimethoprim–sulfamethoxazole (SXT), or a 5-day course of nitrofurantoin.[1] Due to increasing antimicrobial resistance to SXT, empiric therapy with this agent should only be considered if local resistance rate to *E. coli* is less than 20%.[1,9,30] A single dose of fosfomycin may be less effective compared to nitrofurantoin or SXT but is still recommended as a first-line therapy. Fluoroquinolone (as 3-day regimens) and oral β-lactam antimicrobials (3–7-day regimens) can also be used for empiric therapy but should be relegated for use only when one of the three primary treatment options cannot be utilized. Fluoroquinolones are broad-spectrum antimicrobials and have a high propensity to cause collateral damage. Some β-lactams are also broad-spectrum

Table 82–2

Commonly Used Antimicrobial Agents for the Treatment of UTIs

Agent	Comments
Oral Therapy	
Penicillins	
Amoxicillin	Amoxicillin is no longer recommended for empiric therapy due to increasing *Escherichia coli* resistance but can be considered for targeted therapy. Amoxicillin–clavulanic acid can be considered for empiric therapy if a β-lactam must be used.
Amoxicillin–clavulanic acid	
Pivmecillinam	Pivmecillinam is a prodrug of mecillinam and recommended for treatment of acute cystitis. It should be avoided in patients with suspected pyelonephritis. Neither pivmecillinam nor mecillinam is currently approved for use by the US FDA.
Cephalosporins	
Cephalaexin	Oral cephalosporins can be used as alternative therapies for the empiric treatments of UTIs, but they are less effective and have more adverse effects compared to nitrofurantoin and SXT. Concern also exists for use of these agents as a first-line option for uncomplicated cystitis therapy due to potential selection of cephalosporin-resistant organisms.
Cefaclor	
Cefadroxil	
Cefixime	
Cefpodoxime	
Cefuroxime	
Fluoroquinolones	
Ciprofloxacin	Fluoroquinolones are highly effective in the treatment of acute cystitis and pyelonephritis, but bacterial resistance is increasing. They should not be used empirically for acute cystitis due to the risk of collateral damage, unless a first-line agent cannot be used. They are first-line agents for pyelonephritis if *E. coli* resistance in the area is < 10%. Avoid in pregnancy and children. Moxifloxacin should not be used due to limited urinary excretion.
Levofloxacin	
Miscellaneous	
Trimethoprim–sulfamethoxazole	Considered a first-line option for acute cystitis if *E. coli* resistance in the area is < 20%. A 3-day treatment regimen is recommended. It can also be used as prophylaxis for recurrent infections. Generally well tolerated and low cost but increasing resistance rates above 20% in certain regions. Its use may be precluded in patients with sulfa allergies.
Nitrofurantoin	Broad-spectrum agent with a low-risk of collateral damage. Does not penetrate renal tissue well, so should not be used for pyelonephritis. It is considered a first-line agent for acute cystitis and a 5-day treatment is recommended. This agent is effective in treatment and prophylaxis in patients with uncomplicated or recurrent lower tract UTIs. Traditionally, the Beers criteria recommended to avoid use in CrCl < 60 mL/min due to limited urine concentrations, but recent evidence suggests it is effective even with a CrCl as low as 30 mL/min.
Fosfomycin	First-line, single-dose therapy for uncomplicated cystitis. Has been recommended for empiric therapy since resistance rates are low but may have inferior efficacy when compared with short courses of other oral antibiotic agents. Possesses a broad-spectrum of activity, so is sometimes used to treat multidrug-resistant organisms, including ESBL-producing organisms.
Parenteral Therapy	
Aminoglycosides	
Amikacin	Gentamicin and tobramycin given as a consolidated 24-hour dose are recommended as a one-time dose for the treatment of outpatient pyelonephritis, followed by oral antimicrobials, when resistance rates preclude the empiric use of other agents. They can also be used for empiric inpatient treatment of pyelonephritis. Amikacin generally is reserved for multidrug-resistant bacteria. Plazomicin was recently approved for the treatment of complicated UTIs
Gentamicin	
Tobramycin	
Plazomicin	
Penicillins	
Ampicillin	These agents can be used for the treatment of pyelonephritis in the inpatient setting.
Ampicillin–sulbactam	
Piperacillin–tazobactam	
Cephalosporins	
Ceftriaxone	Ceftriaxone is recommended as an initial dose for the treatment of outpatient pyelonephritis when resistance rates preclude the empiric use of other agents. Ceftriaxone and other extended-spectrum cephalosporins can be used in the empiric treatment of pyelonephritis in the inpatient setting. Several new cephalosporins are now approved for the treatment of complicated UTIs caused by multidrug-resistant organisms.
Ceftazidime	
Cefepime	
Ceftolozane/tazobactam	
Ceftazidime/avibactam	
Cefiderocol	
Carbapenems	
Doripenem	Broad-spectrum agents that can be used in the empiric treatment of pyelonephritis in the inpatient setting when multidrug resistance is suspected.
Ertapenem	
Imipenem–cilastatin	
Meropenem	
Meropenem/vaborbactam	
Fluoroquinolones	
Ciprofloxacin	IV dosage forms are considered first-line agents for pyelonephritis if *E. coli* resistance in the area is < 10%. These agents have broad-spectrum activity against both Gram-negative and Gram-positive bacteria. They provide high urine and tissue concentrations. Switch to oral therapy when possible due to excellent bioavailability. Resistance rates are increasing in the United States, so often cannot actually be used as a first-line therapy.
Levofloxacin	

CrCl, creatinine clearance; ESBL, extended-spectrum β-lactamase; FDA, Food and Drug Administration; IV, intravenous; SXT, trimethoprim–sulfamethoxazole; UTI, urinary tract infection.

Table 82–3

Overview of Outpatient, Oral Antimicrobial Therapy for Acute Cystitis, Pyelonephritis, and Prostatitis

Indications	Antibiotic	Adult Dose[a]	Frequency	Duration[b]
Acute Cystitis				
First-line options	Nitrofurantoin monohydrate/macrocrystals	100 mg	Every 12 hours	5 days
Alternative options:	Trimethoprim–sulfamethoxazole	One DS[c] tablet	Every 12 hours	3 days
	Fosfomycin	3000 mg	One-time dose	1 day
	Pivmecillinam[d]	400 mg	Every 12 hours	3–7 days
	Ciprofloxacin	250 mg	Every 12 hours	3 days
	Levofloxacin	250 mg	Every 24 hours	3 days
	Amoxicillin–clavulanic acid	500 mg	Every 8 hours	3–7 days
	Cefdinir	100 mg	Every 12 hours	3–7 days
	Cefaclor	250–500 mg	Every 8 hours	3–7 days
	Cefpodoxime-proxetil	100 mg	Every 12 hours	3–7 days
Recurrent infections—continuous prophylaxis	Trimethoprim–sulfamethoxazole	1/2 SS[e] tablet	Every 24 hours	6 months
	Trimethoprim	100 mg	Every 24 hours	6 months
	Ciprofloxacin	125 mg	Every 24 hours	6 months
	Nitrofurantoin	50 *or* 100 mg	Every 24 hours	6 months
	Cefaclor	250 mg	Every 24 hours	6 months
	Cephalexin	125 mg	Every 24 hours	6 months
Pyelonephritis				
Outpatient treatment	Ciprofloxacin	500 mg	Every 12 hours	7 days
	Ciprofloxacin (extended release)	1000 mg	Every 24 hours	7 days
	Levofloxacin	750 mg	Every 24 hours	5 days
Prostatitis	Trimethoprim–sulfamethoxazole	One DS[c] tablet	Every 12 hours	14 days
	Ciprofloxacin	500 mg	Every 12 hours	2–4 weeks[f]
	Levofloxacin	500 mg *or* 750 mg	Once daily	2–4 weeks[f]
	Trimethoprim–sulfamethoxazole	One DS[c] tablet	Every 12 hours	2–4 weeks[f]

[a] Majority of listed antimicrobial agents require dosage adjustment in patients with significant renal dysfunction.

[b] Duration of therapy may be longer if treating complicated infections.

[c] DS, double strength (160-mg trimethoprim/800 mg-sulfamethoxazole).

[d] Not approved for use by the US FDA.

[e] SS, single strength (80-mg trimethoprim/400-mg sulfamethoxazole).

[f] Treatment should be 6–12 weeks if treating chronic prostatitis.

but are also less efficacious and have a higher incidence of adverse effects compared to the three primary treatments. Ampicillin and amoxicillin should not be considered for empiric therapy due to low efficacy and high rates of resistance.[1]

▶ *Acute Pyelonephritis*

Patients experiencing acute pyelonephritis may be treated in either the outpatient or inpatient settings. Patients who may be dehydrated due to poor fluid intake or severe nausea and vomiting, or those with unstable vital signs should receive inpatient treatment.

Unlike patient with acute cystitis, urine culture and susceptibility testing should always be performed in patients experiencing pyelonephritis. For patients who can be treated as outpatients, oral fluoroquinolones as a 5- or 7-day regimen are the mainstay of therapy if local *E. coli* resistance is less than 10% (see Table 82–3 for specific regimens). A one-time initial dose of IV ciprofloxacin (400 mg) can also be considered. For patients who reside in areas where fluoroquinolone resistance is greater than 10%, oral fluoroquinolones can still be utilized, but an initial dose of IV ceftriaxone (1 g) or a consolidated 24-hour dose of an aminoglycoside should be given. The purpose of this initial IV dose is to provide long-acting empiric coverage while awaiting urine culture results. SXT can be used as a 14-day treatment, but only if susceptibility is confirmed. If SXT is utilized empirically, the initial IV dose of ceftriaxone or an aminoglycoside must be given. Another alternative regimen is an oral β-lactam for 10 to 14 days given with the initial IV dose of ceftriaxone or aminoglycoside. For patients who require empiric inpatient treatment, therapy with one of four general options is recommended: a fluoroquinolone alone; an aminoglycoside with or without ampicillin; an extended-spectrum penicillin or cephalosporin with or without an aminoglycoside; or a carbapenem. Local resistance patterns should be examined to determine appropriate empiric therapy in this case.[1,31,32]

Special Populations

▶ *Pregnant Women*

Pregnant women are predisposed to UTIs due to changes in the urinary tract, including alterations in amino acid and other nutrient concentrations in the urine and physiologic changes such as reduced bladder tone and dilation of the renal pelvis and ureters.[33,34]

UTIs during pregnancy can result in serious complications, such as fetal death, labor complications, mental retardation, and developmental delay.[35,36] Because of these risks, screening for UTIs during pregnancy is recommended, and patients should receive treatment regardless of symptoms.[2,16]. Although the best

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Depression (diagnosed 6 years ago)

FH: Mother living with hypertension and dyslipidemia; father deceased due to lung cancer

SH: Married for 14 years, sexually active; two daughters; occupation: social worker at a local hospital

Allergies: No known drug allergies

Meds: Norethindrone 0.5 mg/ethinyl estradiol daily; fluoxetine 20 mg daily

ROS: (+) dysuria, urinary frequency, flank pain; (–) nausea, vomiting

PE:

VS: BP = 126/78 mm Hg, P 72 = beats/min, RR = 18 breaths/min, T = 38.4°C

CV: RRR, normal S1, S2; normal findings

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly, heme (–) stool

Lab: WBC—13.6 cells/μL (84% neutrophils); all other labs within normal limits; (–) pregnancy test

Urinalysis: Greater than 200 white blood cells/mm^3 (200×10^6/L); urine nitrates positive; leukocyte esterase positive

Urine gram stain: Gram-negative rods, more than 10^5 CFU/mL (10^8 CFU/L)

Local resistance of *Escherichia coli* to SXT and ciprofloxacin is 24% and 20%, respectively

Given this additional information, what is your assessment of the patient's condition?

Identify your treatment goals for the patient.

What nonpharmacologic and pharmacologic alternatives are available for the patient?

length of therapy for pregnant women has not been elucidated, most women typically receive longer durations of therapy than nonpregnancy women. Fluoroquinolones should generally be avoided due to their ability to inhibit cartilage and bone development. SXT has the potential to cause congenital malformations and an increased risk of neonatal kernicterus and should therefore also not be prescribed. Nitrofurantoin can be safely used during pregnancy except in the last 30 days, where it should be avoided due to an increased risk of neonatal jaundice. Most β-lactams are safe in pregnancy and are historically considered first-line options for pregnant patients. Fosfomycin appears safe in pregnancy and can be considered, but less clinical experience exists.[37] In pregnant patients who do experience UTIs, follow-up usually consists of a urine culture 1 to 2 weeks after completion of therapy, then subsequent monthly urine cultures until birth.

Patient Encounter Part 3: Creating a Care Plan

Based on the information presented, create a care plan for this patient's UTI.

Your plan should include:

(a) A statement of the drug-related needs and/or problems,

(b) A patient-specific detailed therapeutic plan, and

(c) Monitoring parameters to assess efficacy and safety.

▸ *Catheterized Patients*

Catheter-associated UTIs (CA-UTIs) are common in patient with an indwelling urinary catheter.[21,38] Bacteria may be introduced into the bladder via the catheter by colonization and direct introduction during catheterization. UTIs as a result of an indwelling catheter are common and occur at a rate of 3% to 8% for each day the catheter is present.[38]

The primary treatment of CA-UTIs is removal and discontinuation of the catheter if possible. In patients without signs and symptoms of infection, removal of the catheter is likely sufficient, and antimicrobials may be withheld. In patients who are symptomatic, antimicrobials should be administered. In all patients, if the catheter cannot be permanently discontinued, a new catheter should be inserted if the previous catheter has been in place for longer than 2 weeks. Empiric antimicrobial regimens for the treatment of CA-UTIs have not been well defined, and treatment should be based on local susceptibility patterns. Results from urinalyses are often difficult to interpret in patients with indwelling catheters as the white blood cell count is usually elevated due to the presence of a foreign material. Urine cultures should always be obtained in CA-UTIs to guide ultimate selection of antimicrobials. In general, treatment for 7 days is sufficient if symptoms promptly resolve and 10 to 14 days if symptoms are slower to resolve.[38]

▸ *UTIs in Men*

KEY CONCEPT UTIs occurring in men are usually due to a structural or functional abnormality of the urinary tract and are therefore usually treated as a complicated infection.[39] For this reason, men should not generally be treated with a single dose or short course of therapy if diagnosed with a UTI. Antimicrobial therapy selection is similar to that used in otherwise healthy women, but men will usually receive 7 to 14 days of treatment.

▸ *Prostatitis*

KEY CONCEPT Prostatitis is an inflammation of the prostate gland due to infection, usually from bacterial causes. Prostatitis can be acute or chronic, with acute being the most common. It is uncommon in young men, but the incidence increases after the age of 30, and as many as half of all men will experience it at some point in their lifetimes. The pathogenesis of prostatitis is not completely understood but likely involves the reflux of infected urine directly into the prostate gland.[40]

Acute prostatitis differs from chronic in their respective signs and symptoms. **KEY CONCEPT** Patients with acute prostatitis present with fever, chills, localized rectal pain, dysuria, urinary straining, increased urinary frequency, and irritation. By contrast, patients with chronic prostatitis rarely present with these symptoms but instead have difficulty urinating, perineal pain, recurrent UTIs, epididymitis, urethritis, or low back pain.[40] The pathogenic organisms responsible for prostatitis are similar to those that cause UTIs, with *E. coli* accounting for 75% of cases. *K. pneumoniae* and *P. mirabilis* can also be implicated, with other Enterobacteriaceae, such as *Pseudomonas*, being infrequent causes. *Staphylococcus* is a rare but possible cause as well. Some men may also experience prostatitis following infection with the

Table 82–4

Monitoring Parameters for Select Antibiotics Used in the Treatment of UTIs

Drug Class or Drug	What to Monitor	Frequency	Endpoint
Aminoglycosides	SCr, urine output	Every 24 hours	Prevention of nephrotoxicity manifested by a rise in SCr
	Aminoglycoside serum concentrations	Depends on duration of therapy. At least once weekly; more frequently if evidence of changing renal function	Trough serum concentrations < 2 mg/L or < 8 mg/L for amikacin, to decrease risk of nephrotoxicity and ototoxicity. Peak goal 5–6 mg/L. If using extended-interval dosing, monitoring should be based on the specific nomogram chosen
Nitrofurantoin	SCr	Only if renal function changing or unstable	Nitrofurantoin metabolites may accumulate in renal insufficiency and lead to neuropathy; avoid if CrCl < 30 mL/min
	Liver profile	Periodic monitoring	Prevention of cholestasis
Nitrofurantoin Tetracyclines Sulfonamides	SCr	Only if renal function changing or unstable	Decreases in glomerular filtrate rate can significantly decrease the urine concentration of these agents

CrCl, creatinine clearance; SCr, serum creatinine.

sexually transmitted infections *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. Chronic prostatitis usually occurs after a patient experiences acute prostatitis when the infecting organism is not completely removed from the prostate. Therefore, the same pathogens responsible for acute prostatitis also cause chronic.[41]

Acute prostatitis can be readily diagnosed based on symptoms and the presence of significant bacteriuria. The diagnosis of chronic prostatitis is more difficult due to the infrequent prostate symptoms. It is generally diagnosed when a male patient has a recurring UTI with the same organism each time.[40]

The pharmacologic treatment approach to the management of prostatitis is similar to that of UTIs. Antimicrobial penetration of the prostate must be taken under consideration as many antimicrobials do not penetrate well into prostatic tissue and fluids, although concentrations are improved through the inflammatory process in acute prostatitis. **KEY CONCEPT** Fluoroquinolones and SXT are considered the treatments of choice for prostatitis due to their activity against the most common organisms and their penetration into prostatic fluid. However, as discussed previously, bacterial resistance to these agents is increasing. Alternative agents to be considered include cephalosporins (such as cephalexin or cefuroxime) and penicillins (such as amoxicillin/clavulanate). Initial therapy with an IV agent may be necessary in some cases of acute prostatitis based on the clinical stability of the patient. Acute prostatitis should be treated for at least 2 weeks and can be extended to 4 weeks if patients are slow to improve. Chronic prostatitis is treated for a longer period of time, usually 6 weeks, but possibly up to 12 weeks.[40,42,43]

Outcome Evaluation for UTIs

- Monitor the patient for resolution of symptoms with the goal of 48 to 72 hours to resolution after start of antimicrobial therapy.
- Follow up with urine culture results to deescalate antimicrobial therapy if possible.
- Repeat urine culture is necessary only if symptoms do not acutely abate, reinfection, or recurrence occurs. Resistance rates to *E. coli* are increasing to antibiotics commonly prescribed for UTI, and certain isolates are multidrug resistant.[44]
- Depending on the chosen antibiotic therapy, evaluate the patient based on drug therapy–monitoring parameters including those presented in Table 82–4 to optimize therapy and decrease incidence of adverse events.

Patient Care Process

Collect Information:

- Based on physical examination, signs and symptoms, review of systems, and urinalysis, determine whether the patient is experiencing a UTI.
- Obtain the patient's medication history and risk factors for an antibiotic-resistant infection.
- Assess patient renal function and other laboratory tests for antibiotic dosing and systemic complications.
- Identify potential sources of infection, such as indwelling urinary catheters.

Assess the Information:

- Based on urinalysis and gram stain (if available), determine whether the empiric antibiotic selection is appropriate.
- Based on culture and susceptibility data (if available), determine whether any changes should be made from your initial empiric antimicrobial selection (ie, resistance to the regimen initially selected). Also, assess if the empiric antimicrobial selected can be deescalated to a lower-spectrum agent.

(Continued)

Patient Care Process (*Continued*)

- Evaluate the patient's symptoms to determine response to the antimicrobial regimen chosen.
- Evaluate the patient for the presence of adverse drug events, drug allergies, and potential drug interactions.

Develop a Care Plan:

- Determine the optimal antibiotic dose and duration of therapy based on the patient and infection type (complicated vs uncomplicated).
- Determine whether the patient may benefit from prophylactic therapy (ie, recurrent UTIs secondary to chronic urinary catheterization due to paraplegia).
- Identify lifestyle modifications as needed to minimize UTI recurrence.

Implement the Care Plan:

- Prescribe and dispense the optimal antibiotic at the correct dose and duration.
- Recommend lifestyle changes, if needed.

Follow-up: Monitor and Evaluate:

- Stress the importance of complying with the prescribed antimicrobial regimen and to follow up with the healthcare provider if signs and symptoms recur.

ACKNOWLEDGMENT

The authors and editors wish to acknowledge and thank Dr. Warren Rose, the primary author of this chapter in the third edition of this book.

Abbreviations Introduced in This Chapter

ASB	Asymptomatic bacteriuria
BPH	Benign prostatic hypertrophy
CA-UTI	Catheter-associated UTI
CFU	Colony-forming units
CrCl	Creatinine clearance
ESBL	Extended-spectrum β-lactamase
IV	Intravenous
SCr	Serum creatinine
SXT	Trimethoprim–sulfamethoxazole
UTI	Urinary tract infection
VUR	Vesicouretal reflux

Sexually Transmitted Infections

Marlon S. Honeywell and Evans Branch, III

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Assess the behavioral considerations and the importance of contraception with regard to the contributing factors of sexually transmitted infections (STIs).
2. Apply the "patient-delivered partner therapy" method when recommending treatment for STIs.
3. Describe the patient populations that are typically affected by specific STIs.
4. Identify causative organisms for STIs.
5. Devise a list of the clinical signs and symptoms corresponding to each type of STI and classify patients based on recommended criteria.
6. Select appropriate diagnostic procedures for STIs.
7. Recommend STI treatment regimens and recommend therapy, when appropriate.
8. Develop monitoring parameters based on recommended regimen.

INTRODUCTION

Though we have made significant progress in science and medicine, longstanding problems of infectious disease continue to plague us.[1] Even with the discovery of newly improved antibiotics, sexually transmitted infections (STIs) have not yet been eradicated. Several have reemerged secondary to modern social trends (eg, number of partners, sex workers, and swingers) of sexual activity, socioeconomic concerns, and the global lack of preventive education. **KEY CONCEPT** Since the correlation between risky sexual behavior and STIs is well documented,[2] many sexually active individuals may contract an infection at some point in their lives. Community approaches to reducing STIs (eg, access to quality health care, promotion of personal health, and advancement of community wellness) have been proven effective.[3] Though inconsistent and incorrect condom use increases the probability of new STIs, counseling patients on the consistent use of condoms, spermicides, or diaphragms is also important component in reducing overall incidence. Additionally, healthcare providers who manage persons at risk for STIs should counsel women concerning the option for emergency contraception, when indicated. Mifepristone, levonorgestrel, ulipristal, ethinyl estradiol, and copper T intrauterine devices have been employed in the United States for the prevention of unintended pregnancy.[4]

Optimal detection and treatment of sexually transmitted diseases depend on counseling by a patient-friendly and knowledgeable clinician who can effectively establish open communication. Acknowledging the hierarchy of human needs is the cornerstone to establishing open communication. When these needs are met in a safe and collaborative environment, it increases patients' confidence and gives them a sense of trust, which encourages interpersonal and open communication. Open communication with patients may also be encouraged by (a) incorporating training on effective communication within the organization's mandatory training program, (b) making communication a part of the organization's culture, (c) implementing patient satisfaction surveys, (d) utilizing technology when appropriate, and (e) ensuring that continuous quality improvement is incorporated. Additionally, clinicians, healthcare workers, and healthcare facilities should strive to incorporate strategies regarding communication improvement, especially when suggested by patients.

In addition to an increasing number of adolescents and young adults engaging in unsafe sexual practices, there is a high incidence of men who have sex with men (MSM) and women who have sex with women (WSW). In fact, MSM is documented as the risk group most severely affected by HIV in the United States. Changes in sexual behaviors and STI diagnosis was noted in patients who used pre-exposure prophylaxis (PrEP). PrEP is discussed in detail in Chapter 87 (HIV). Among MSM using PrEP, STIs were highly concentrated among a subset, and receipt of PrEP was associated with an increased incidence of STIs.[5] These findings highlight the importance of frequent STI testing among gay and bisexual men using PrEP. Although limited data are available with regard to STIs in WSW, transmission generally occurs through fisting, fingering, oral sex, menstrual blood, or the use of sexual toys. Additionally, if bisexual, transmission may also occur when WSW are involved with male partners. The chances of transmission are higher if a WSW has gingivitis and performs unprotected oral sex, and if the same occurs during the menstrual cycle of the receiver.[6] Sharing penetrative items or employing practices involving digital vaginal or digital anal contact most likely represent the most common modes of transmission. This possibility is supported by reports of metronidazole-resistant trichomoniasis and genotype-specific HIV transmitted sexually between women who reported such behaviors and an increased prevalence of bacterial vaginosis (BV) among monogamous WSW. Additionally, when screening for STIs, special populations must be considered, which include pregnant women, transgender men and women, and women in correctional facilities. Data suggests that clinicians should assess, respectively, STI-related risks for the special populations based on sexual identity, practices, and risk behaviors.

Sexual abuse in adolescents and children is becoming more ubiquitous in the United States. STIs are rare in sexually abused children and adolescents. However, when present, they can be crucial to making the diagnosis of sexual abuse and protecting children.[7] Children or adolescents with an STI should be evaluated for sexual abuse. The identification of an STI in a child can have serious medical and legal implications and is used to support the presence or allegation of abuse. In cases of abusive contact, commonly found infections include *Neisseria gonorrhoeae* or *Chlamydia trachomatis*. Abusive cases should be reported to Child Protective Services.

Defined as a person who engages in the exchange of spouses for sexual activities, the emergence of "swingers" as a new category of at-risk patients has been seen in STI clinics throughout the world. In a study conducted by Spauwen et al., the authors concluded that approximately half of STI clinic–attending swingers whose sexual behavior agrees with the definition of swinging do not identify themselves as such. As many STI clinics internationally do not specifically ask clients about their swinging behavior, swingers may be a missed target population in care.[8] Most swingers are likely to be diagnosed with HIV, herpes, chlamydia, or gonorrhea. To this end, although little data exists, swingers now represent a group with risky behaviors that must be identified and treated, when necessary.

KEY CONCEPT Optimally, both sex partners should be treated simultaneously for an STI. Clinics and health departments often proactively attempt dual treatment by providing a prescription for the partner to the index patient (the patient who is evaluated by a clinician), a practice commonly known as patient-delivered partner therapy. Medications or prescriptions should be accompanied by treatment instructions and appropriate warnings. Counseling regarding the appropriate use of condoms, cervical diaphragms, spermicides, and emergency contraception is also important to mitigate the occurrence of reinfection.

Accurate reporting of STIs is imperative to the evaluation of trends in sexual behaviors; reporting may be provider- or laboratory-based. State and local health departments may assist with the mechanism by which STI cases are reported in accordance with statutory requirements. Confidentiality should always be exercised in such cases.[9,10]

GONORRHEA

INTRODUCTION

A curable STI caused by the Gram-negative diplococcus *N. gonorrhoeae*, gonorrhea is the second most commonly reported bacterial STI. Proper therapeutic management with antimicrobial agents is essential to eradicate this infection and prevent the development of associated sequelae, such as urethritis, cervicitis, or dysuria. There are currently no vaccines available for gonorrhea.

EPIDEMIOLOGY AND ETIOLOGY

In the United States, diagnosis of gonorrhea increased by 5% in the past 5 years. The highest rate of gonococcal infection is seen within the 15- to 24-year-old age groups for both sexes, although more cases are reported in men.[9,10] Factors associated with an increased risk of infection include ethnicity (ie, African Americans aged 15–24), low socioeconomic status, illicit drug use, and age (ie, < 25 years of age and older women at increased risk of infection [ie, new sex partner, more than one sex partner, or a partner who has a STI]). Strategic screening of young women, less than 25 years of age, who are at an increased risk has been correlated to gonorrhea control in the United States.[9] In fact, the risk of a cervical infection after a single episode of vaginal intercourse is approximately 50% and increases with multiple exposure. Furthermore, rates of reinfection are significantly higher among ethnic minorities. Additionally, routine screening should be considered for sexually active MSM and WSM, bisexual men and women, pregnant women, swingers, and transgender men and women. Targeted screening of high-risk populations may reduce the number of new infections and associated sequalae.

PATHOPHYSIOLOGY

Attachment to mucosal epithelium, mediated in part by pili and opa (outer membrane opacity proteins), is followed by penetration of *N. gonorrhoeae* through epithelial cells into the submucosal tissue within 24 to 48 hours. A vigorous response by neutrophils begins with sloughing of the epithelium, development of submucosal microabscesses, and exudation of pus. Stained smears usually reveal large numbers of gonococci within a few neutrophils, whereas most cells contain no organisms.[11]

CLINICAL PRESENTATION AND DIAGNOSIS

Several laboratory tests are available to aid in the diagnosis of gonorrhea and include Gram-stained smears, endocervical or vaginal specimens, culture, or the DNA hybridization probe.

Clinical Presentation and Diagnosis of Gonorrhea[9-11]

General

- Purulent discharge
- Greater urinary frequency
- Persistent sore throat

Signs

- Painful or swollen testicles
- Tubal scarring

Symptoms

Men:

- May be asymptomatic, though acute urethritis is the predominant manifestation
- Urethral discharge and dysuria, usually without urinary frequency or urgency
- When compared with nongonococcal urethritis, the discharge in gonococcal urethritis is generally more profuse and purulent
- Pain during urination

Women:

- May be asymptomatic
- Cervicitis, urethritis, increased vaginal discharge, dysuria, and intermenstrual bleeding
- Pain during urination
- Abdominal pain

A Gram stain of a male urethral specimen that demonstrates polymorphonuclear leukocytes with intracellular Gram-negative diplococci may be considered diagnostic in symptomatic men. A Gram-negative stain is insufficient for ruling out infection in asymptomatic men.[9] Additionally, Gram stain of endocervical, pharyngeal, or rectal specimens are also insufficient to detect infections. All patients who test positive for gonorrhea should be tested for other STIs, including chlamydia, syphilis, and HIV. The recommended method for gonorrhea testing, however, is the nucleic acid amplification test (NAAT), which detects the genetic material for *N. gonorrhoeae*. Specimen may be collected from the urine, vagina, rectum, conjunctiva, nasopharynx, and conjunctiva.

TREATMENT

The desired outcome is complete eradication of *N. gonorrhoeae* and avoidance of sequelae.

Pharmacologic Therapy[4,9,10,13,14]

KEY CONCEPT Patients infected with gonorrhea are often coinfected with *C. trachomatis* and should receive concurrent therapy to eradicate both organisms. Treatment is now complicated by the development of resistance to *N. gonorrhoeae*. To mitigate the probability of resistance, the most recent guidelines recommend the combination of cephalosporins and azithromycin or doxycycline (ie, uncomplicated gonococcal infections).[9,10] The treatment algorithm for gonorrhea may be found in Table 83–1.

▶ Side Effects and Contraindications

- *Cephalosporins:* Side effects include black tarry stools, diarrhea (pseudomembranous colitis) chills, cough, fever, and swollen glands. Contraindications include hypersensitivity to ceftriaxone or cephalosporins.
- *Azithromycin:* Side effects include diarrhea, nausea, abdominal pain, and palpitations. Contraindications include hypersensitivity to azithromycin, erythromycin, other macrolide antibiotics (eg, azalide or ketolide) antibiotics or any component of the formulation.
- *Doxycycline:* Side effects include increase in blood pressure, diarrhea, abdominal distention, increased serum aspartate aminotransferase, nasopharyngitis, sinus headache, and fungal infection. Contraindications include hypersensitivity to doxycycline, tetracyclines, or any component of the formulation.
- *Aminoglycosides:* Side effects include renal toxicity, ototoxicity, dizziness, increased or decreased frequency of urination, increased thirst, loss of appetite, vomiting, burning of face and mouth (streptinomycin only), and numbness. Contraindications include hypersensitivity to aminoglycosides or any component of the formulation.
- *Spectinomycin:* Side effects nausea, dizziness, soreness at injection site, hives, insomnia, chills, and fever. Contraindications include in patients who have hypersensitivity to it.
- *Erythromycin:* Nausea, diarrhea, stomach pain, and dark urine. Contraindications include hypersensitivity to this antibiotic. Additionally, erythromycin is contraindicated in patients taking terfenadine, astemizole, pimozide, or cisapride.

▶ Recommendations During Pregnancy

- Pregnant women should be treated with a recommended or alternative cephalosporin. Ceftriaxone 250-mg IM plus azithromycin 1 g PO may be employed.
- For women who cannot tolerate a cephalosporin, azithromycin 2 g PO may be prescribed. When allergies or other issues preclude treatment, consultation with an infectious disease specialist is recommended.

▶ Allergy, Tolerance, or Adverse Reactions

- When cephalosporin allergy is a consideration, single doses of gemifloxacin 320 mg PO *plus* azithromycin 2 g or dual treatment with single doses of IM gentamicin 240 mg *plus* azithromycin 2 g may be used.
- Spectinomycin for treatment of urogenital and anorectal gonorrhea can be considered when available.
- Doxycycline and fluoroquinolones are contraindicated.

▶ Expedited Partner Treatment for Uncomplicated Urogenital, Rectal, or Pharyngeal Gonococcal Infection[10]

- The partner may be treated with a single 800-mg oral dose of cefixime, if chlamydial infection has been excluded.
- If chlamydial infection is confirmed, the partner may be treated with a single oral 800-mg cefixime dose plus oral doxycycline 100 mg twice daily for 7 days.

▶ Cephalosporin Treatment Failure[10]

- Suspect treatment failure in (a) persons whose symptoms do not resolve in 3 to 5 days after treatment and report no sexual contact during post-treatment follow-up, (b) persons with a positive test-of-cure (ie, positive culture ≥ 72 hours or positive NAAT ≥ 7 days after receiving recommended treatment) when no sexual contact is reported during the post-treatment follow-up period, and (c) persons who have a positive culture on test-of-cure if there is no evidence of decreased susceptibility to cephalosporins on antimicrobial susceptibility testing.
- Obtain relevant clinical specimen for culture and antimicrobial susceptibility testing.
- Consult an infectious disease specialist or STI expert for guidance in management.
- Report the case to the Center of Disease Control (CDC) within 24 hours.
- Prioritize notification and culture evaluation for the patient's partner(s) from the requisite 60 days for those with suspected cephalosporin treatment failure or persons whose gonococcal isolates show mitigated susceptibility to cephalosporins.

OUTCOME EVALUATION

- Order diagnostic test for gonorrhea. If positive, recommend antibiotics that cover gonorrhea and chlamydia.
- Provide treatment for partner to mitigate the probability of reinfection.
- Counsel patient on the significance of refraining from sex for 7 days after treatment.
- Subsequent to treatment, expect the eradication of organisms responsible for gonorrhea and chlamydia.
- Order a test-of-cure 14 days after treatment for patients with pharyngeal gonorrhea who were treated with an alternative regimen.
- Retest after 3 months for men or women who have been treated for gonorrhea, irrespective of whether sex partners

Table 83–1

Treatment Recommendations for Gonorrhea

Indications	Drugs	Dose	Route	Duration	Alternative	Allergies
Uncomplicated Gonococcal Infection of the Urogenital, Rectum, or Pharynx and Rectum MSM or Heterosexuals with a History of Recent Travel[a]	Ceftriaxone ***Dose by Weight***				Cefixime 800 mg PO as a single dose if ceftriaxone is unavailable	Cephalosporin: Gentamicin 240 mg IM PO *plus* azithromycin 2 g dual treatment
	(< 150 kg)	500 mg	IM	One-time dose		
	(≥ 150 kg)	1 g	IM	One-time dose		
	and					
	Doxycycline *(if chlamydia is not excluded)*	100 mg	PO	Twice daily For 7 days		
Gonococcal Arthritis[a]	Ceftriaxone	1 g	IM or IV	Every 24 hours for 7 days		Cephalosporin: Gemifloxacin 320 mg PO plus azithromycin 2 g or dual treatment with single doses of IM gentamicin 240 mg *plus* azithromycin 2 g
	and					
	Azithromycin	1 g	PO	For 7 days		
Pregnancy and Gonococcal Infection[a]	Ceftriaxone	250 mg	IM		Azithromycin 2 g PO as a one-time dose	Cephalosporin: Gemifloxacin 320 mg PO plus azithromycin 2 g or dual treatment with single doses of IM gentamicin 240 mg *plus* azithromycin 2 g
	and					
	Azithromycin	1 g	PO			
Disseminated Gonococcal Infection[a]	Ceftriaxone	1 g	IM or IV every 24 hours	For 24-48 hours after improvement is noted	Cefotaxime 1 g IV every 8 hours or ceftizoxime 1 g IV every 8 hours plus azithromycin 1 g PO as a single dose	
	and					
	Azithromycin	1 g	PO			
Gonococcal Conjunctivitis[a]	Ceftriaxone	1 g	IM	One-time dose	One-time lavage of the eye(s) once with saline (consult with infectious disease specialist)	
	and					
	Azithromycin	1 g	PO	One-time dose		
Uncomplicated Infections of the Cervix, Urethra, and Rectum in Children Less Than 45 kg	Ceftriaxone	250 mg	IM	One-time dose		
	or					
	Spectinomycin	40 mg/kg	IM	One-time dose (not to exceed 2 g)		
Gonococcal Scalp Access in Newborns	Ceftriaxone	25–50 mg/kg/day	IM or IV	7 days		
	or					
	Cefotaxime	25 mg/kg every 12 hours	IM or IV	7 days Both medications may be used for 10–14 days if meningitis is documented.		
Gonococcal Meningitis[a]	Ceftriaxone	1–2 g	IV	Every 12–24 hours for 10–14 days		
	and					
	Azithromycin	1 g	PO	One-time dose		
Gonococcal Endocarditis[a]	Ceftriaxone	1–2 g	IV	For at least 4 weeks		
	and					
	Azithromycin	1 g	PO	One-time dose		

(Continued)

Table 83–1

Treatment Recommendations for Gonorrhea (*Continued*)

Indications	Drugs	Dose	Route	Duration	Alternative	Allergies
Ophthalmia Neonatorum Prophylaxis	Erythromycin	0.5%	Into the affected eye(s)	One-time dose		
Gonococcal Ophthalmia	Ceftriaxone	25–50 mg/kg	IM or IV	One-time dose (not to exceed 125 mg)		
Neonates Born to Mothers Who Have Gonococcal Infection	Ceftriaxone	25–50 mg/kg	IM or IV	One-time dose (not to exceed 125 mg)		
Infants and Children Who Weigh ≤ 45 kg and Who Have Uncomplicated Gonococcal Vulvovaginitis, Cervicitis, Urethritis, Pharyngitis or Proctitis	Ceftriaxone	25–50 mg/kg	IM or IV	One-time dose (not to exceed 125 mg)		
Infants and Children Who Weigh > 45 kg and Who Have Uncomplicated Gonococcal Vulvovaginitis, Cervicitis, Urethritis, Pharyngitis, or Proctitis (Adult Dose Recommended)[a]	Ceftriaxone ***Dose by Weight*** (< 150 kg) (≥ 150 kg) and Doxycycline *(if chlamydia is not excluded)*	 500 mg 1 g 100 mg	 IM IM PO	 One-time dose One-time dose Twice daily For 7 days		
Recommended Regimen for Children Who Weigh ≤ 45 kg and Who Have Bacteremia or Arthritis	Ceftriaxone	50 mg/kg	IM or IV	As a single dose daily for 7 days		
Recommended Regimen for Children Who Weigh > 45 kg and Who Have Bacteremia or Arthritis	Ceftriaxone	1 g	IM or IV	As a single dose daily for 7 days		

[a]Treatment for both *Neisseria gonorrhoeae* and *Chlamydia trachomatis* may be indicated based on infection type and host.

Data from Refs. [9,10,12,15,16,17].

were treated. If retesting is impossible at 3 months, retest at the next medical visit within 12 months following treatment.

- Symptoms that persist after treatment should be evaluated by culture for *N. gonorrhoeae* and any gonococci isolated should be tested for antimicrobial susceptibility.

CHLAMYDIA

INTRODUCTION

Chlamydia is a STI caused by the bacteria *C. trachomatis*. Individuals infected with chlamydia are usually asymptomatic and the infection is easily treated with antibiotics. No vaccine exists for this infection.

EPIDEMIOLOGY AND ETIOLOGY

Infection with *C. trachomatis* has increased dramatically in recent years. In 2018, 1,758,668 cases of chlamydia were reported to the CDC, corresponding to a rate of 539.9 cases per 100,000 population. Chlamydia is most common among young people. Almost two-thirds of new chlamydia infections occur among youth aged 15 to 24 years.[9-11] Substantial racial disparities in chlamydia infection exist,

Patient Encounter 1

TS is a 20-year-old Mexican woman that works as a cross fit trainer at the local gym. Although TS generally understands English, she does not speak it fluently. She is currently enrolled in night courses to improve English comprehension.

Upon her last gynecology visit, a test for STIs was initiated due to a prescription she found at one of her boyfriend's home for erythromycin 500 mg that was prescribed four times daily for 7 days. Although asymptomatic, the results of TS's diagnostic test reveal her culture is positive for chlamydia.

PMH: Asthma; no prior history of STIs

Meds: Advair HFA 250/50 twice daily, CBD oil for anxiety

What information is suggestive of chlamydia?

What risk factors does she have for chlamydia?

Should any cultural competence concerns be considered?

Clinical Presentation of Chlamydia[9,10,11,14]

General

- Asymptomatic

Signs

- Beefy red cervix that bleeds easily (women)

Symptoms

- When present, the urethral discharge is watery and slightly purulent. Complications resulting from lack of treatment or inadequate treatment include epididymitis (in men), and pelvic inflammatory disease (PID) including associated complications in women.

Other Diagnostic Tests

- Culture can be positive for both chlamydia and gonorrhea.
- Gonorrhea and chlamydia should be treated concomitantly.

with a prevalence among non-Hispanic Black patients 5.6 times the prevalence among non-Hispanic White patients. Chlamydia is also common among MSM. Among MSM screened for rectal chlamydia infection, 0.5% to 2.3% were positive. Many cases remain unreported because most people are asymptomatic and do not seek testing. This bacterium is the most common cause of nongonococcal urethritis, accounting for as many as 40% of cases.

PATHOPHYSIOLOGY

C. trachomatis possesses characteristics resembling both bacteria and viruses. Its major membrane is comparable to that of Gram-negative bacteria, although it lacks a peptidoglycan cell wall and requires cellular components from the host for replication. Chlamydia transmission risk is thought to be less than that of gonorrhea.

CLINICAL PRESENTATION AND DIAGNOSIS

Common tests used to diagnose *C. trachomatis* include the NAAT, culture, enzyme immunoassay, DNA hybridization probe, or the direct fluorescent monoclonal antibody test. The NAAT is the most sensitive exam and the one which is commonly seen in practice.

Diagnosis has been confirmed in women through first-catch urine or swab specimens collected from the endocervix and in men using a urethral swab or first-catch urine specimens. Most women are asymptomatic; therefore, an annual screening or physical is necessary, as early detection may reduce rates of transmission.

Screening young sexually active men is recommended in clinical settings with a high prevalence of chlamydia (eg, correctional facilities, adolescent clinics) or areas with high infection rates. The primary focus for women should be to detect chlamydia, present complications, and to test and treat their partners. In some cases, frequent screening for certain women (eg, adolescents) and men (eg, MSM) is suggested.

TREATMENT[9,19]

The desired outcome is complete eradication of *C. Trachomatis* and avoidance of sequelae.

Pharmacologic Therapy[4,9,13,14]

Pharmacologic therapy for the treatment of chlamydia may be found in Table 83–2.

▶ *Recommendations During Pregnancy*

The recommended regimen for pregnant patients is azithromycin 1 g PO as a single dose *or* amoxicillin 500 mg three times daily for 7 days *or* erythromycin 500 mg four times daily for 7 days *or* 250 mg four times daily for 14 days.

Azithromycin 1 g orally as a single dose *or* amoxicillin 500 mg orally three times daily for 7 days *or* erythromycin base 500 mg orally four times daily for 7 days *or* erythromycin 250 mg orally four times daily for 14 days *or* erythromycin ethylsuccinate 800 mg orally four times daily for 7 days *or* erythromycin ethylsuccinate 400 mg orally four times daily for 14 days is recommended.

▶ *C. trachomatis Infection in Infants*

Treatment of ophthalmia neonatorum or infant pneumonia should be with erythromycin base or ethylsuccinate 50 mg/kg/day PO divided into four doses daily for 14 days. An association between oral erythromycin and infantile hypertrophic pyloric stenosis (IHPS) has been reported in infants aged less than 6 weeks, who were treated with this drug. Infants treated with erythromycin should be monitored for signs and symptoms of IHPS.

OUTCOME EVALUATION

- Order diagnostic test for chlamydia. If positive, recommend antibiotics that cover gonorrhea and chlamydia.
- Provide treatment for partner to mitigate the probability of reinfection.
- Counsel patient on the significance of refraining from sex for 7 days after treatment.
- Test of cure to detect therapeutic failure (ie, repeat testing 3–4 weeks after completing therapy) is not advised for individuals treated with the recommended or alternative regimens, unless therapeutic adherence is questionable, symptoms persist, or reinfection is suspected.
- Retest for chlamydia approximately 3 months after treatment, irrespective of whether sex partner was treated.

SYPHILIS

Attributed to the spirochete *Treponema pallidum*, syphilis can have numerous and complex manifestations. Clinician familiarity, stage-specific diagnosis, and effective treatment are vital. Missed or inappropriately treated syphilis may result in cardiovascular complications, neurologic disease, or congenital syphilis. No vaccine exists for syphilis.

EPIDEMIOLOGY AND ETIOLOGY

The incidence of syphilis declined drastically following the introduction of penicillin; however, prevalence rose when HIV arrived from obscurity in the 1980s. In 2018, there were more than 115,000 cases reported. Rates of primary and secondary syphilis increased 14% to more than 35,000 cases, the highest number reported since 1991.[20] Additionally, a dangerous trend of congenital syphilis has emerged: a 40% increase in cases was noted, and five states—Texas, California, Florida, Arizona, and Louisiana—accounted for 70% of cases. Data suggests

Table 83–2

Treatment Recommendations for Chlamydia

Indications	Drugs	Dose	Route	Duration	Alternative	Allergies
Uncomplicated Genital	Azithromycin Doxycycline	1 g 100 mg	PO PO	One-time dose (drug of choice) Twice daily for 7 days	Erythromycin 500 mg PO four times daily for 7 days OR erythromycin ethylsuccinate 800 mg four times daily OR levofloxacin 500 mg PO once daily for 7 days OR ofloxacin 300 mg twice daily (or 600 mg once daily) for 7 days	
Anorectal Infection	Azithromycin Doxycycline	1 g 100 mg	PO PO	One-time dose Twice daily for 7 days		
Chronic Reactive Arthritis	Doxycycline Rifampin	100 mg 300 mg	PO PO	Twice daily for 7 days Once daily for 6 months		
Uncomplicated Urethral, Endocervical or Rectal Infections in Adults	Azithromycin Doxycycline	1 g 100 mg	PO PO	One-time dose Twice daily for 7 days	Erythromycin 500 mg PO four times daily for 7 days OR erythromycin ethylsuccinate 800 mg four times daily OR levofloxacin 500 mg PO once daily for 7 days OR ofloxacin 300 mg twice daily (or 600 mg once daily) for 7 days ***Pregnancy*** Azithromycin 1 g PO as a single dose OR Amoxicillin 500 mg three times daily for 7 days OR Erythromycin base 500 mg four times daily for 7 days OR Erythromycin 250 mg four times daily for 14 days OR Erythromycin ethylsuccinate 800 mg four times daily for 7 days OR Erythromycin ethylsuccinate PO four times daily for 14 days	Erythromycin base 500 mg PO four times daily for 7 days OR Erythromycin base 250 mg PO four times daily for 14 days OR Erythromycin ethylsuccinate 800 mg PO four times daily for 7 days OR Erythromycin ethylsuccinate 400 mg PO four times daily for 14 days
Infection in Infants[a]	Azithromycin	1 g	PO	For 24–48 hours after improvement is noted; Ceftriaxone 1 g IV/IM indicated for concurrent *Neisseria gonorrhoeae* treatment	Cefotaxime 1 g IV every 8 hours or ceftizoxime 1 g IV every 8 hours plus azithromycin 1 g PO for 24–48 hours after improvement is noted	

[a] Treatment for both *Neisseria gonorrhoeae* and *Chlamydia trachomatis* may be indicated based on infection type and host.

Data from Refs. [9,10,14-18].

that several factors account for the elevation of cases reported, including gaps in testing, lack of treatment during prenatal care, drug use, poverty, decreased condom use, and cuts to STI programs at the state and local level.[9] Currently, no vaccine exists for this infection.

PATHOPHYSIOLOGY

T. pallidum rapidly penetrates intact mucous membranes or microscopic dermal abrasions, and within a few hours, the organism enters the lymphatics and blood to produce systemic illness. During the secondary stage, examinations commonly demonstrate abnormal findings in the cerebrospinal fluid (CSF). As the infection progresses, the parenchyma of the brain and spinal cord may subsequently be damaged.

DIAGNOSIS AND CLINICAL PRESENTATION

Stages of Syphilis

▶ *Primary Syphilis*

Usually manifests as a solitary, painless chancre. Primary syphilis develops at the site of infection approximately 3 weeks after exposure to *T. pallidum*; the chancre is highly infectious. The ulcer is typically indurated without exudate. There may be regional lymphadenopathy.[9,21]

▶ *Secondary Syphilis*

Without appropriate treatment, primary syphilis will advance to secondary syphilis—a stage usually apparent from its clinical symptomatology. Symptoms include fatigue, diffuse maculopapular rash involving the trunk, sore throat, myalgias, malaise, fever, lymphadenopathy, and genital or perineal condyloma latum. Hepatitis, patch alopecia, and renal insufficiency may also be seen. Ocular manifestations may include retinitis, optic neuritis, and uveitis.

▶ *Latent Syphilis*

Early Latent Individuals who have latent syphilis and who acquired syphilis during the preceding year are classified as early latent. Although, in this stage, the absence of signs and symptoms may be noted, serologic tests are positive. Usually occurs during the first year after infection and may be established in patients who have seroconverted, had symptoms of primary or secondary syphilis, or had sex with a partner with primary, secondary, or latent syphilis.

Late Latent Patients should be considered to have late latent syphilis, if the aforementioned criteria (early latent) are not met. In both stages, patients are usually asymptomatic, and the lesions noted in the primary and secondary phase usually resolve; however, individuals are still seropositive for *T. pallidum*.

Tertiary Syphilis Develops years (one or more decades) after the initial infection and may involve any organ in the body. Progressive dementing illness and tabes dorsalis are considered classic late neurological manifestations. Aortitis, cardiovascular disease (ie, aortic aneurysm, aortic valve insufficiency, and coronary stenosis), and nodular lesions in skin and bones may also be seen.

Congenital Syphilis

Congenital syphilis is a condition in which the fetus is infected with *T. pallidum* as a result of the hematogenous spread from an infected mother, although transmission may also occur from direct contact with the infectious genitalia of the mother. Since the primary stage of syphilis is characterized by spirochetemia, infectious rates of the fetus are nearly 100% if the mother has untreated primary syphilis, resulting in a 40% fetal death rate in infected infants.[21,22]

Diagnostic Procedures

There are three basic tests used in screening for syphilis. Diagnostic procedures include dark-field microscopy, nontreponemal exams (ie, the Venereal Disease Laboratory [VDRL] and the rapid plasma reagin [RPR] test), and treponemal exams (ie, enzyme immunoassay, the *T. pallidum* hemagglutination test, the fluorescent treponemal antibody test, and the enzyme-linked immunosorbent assay [ELISA]).[9,21] The paradigm recently shifted in many health centers to screen first with a treponemal antibody test and order a nontreponemal test only if the treponemal test is positive.

In a healthy patient, tests should be negative. This means that no antibodies to *T. pallidum* should be present. However, even if one of the aforesaid tests is positive, it would be inappropriate to provide an opinion about the infective status of the patient. Therefore, a good history should be taken and additional tests performed to exclude other diseases and scenarios, which may yield a false-positive result. Serologic exams generally provide indirect evidence of syphilis and may be reactive in the absence of clinical or historical evidence. Reactivity, in such cases, is usually in low dilutions (< 1:8); however, false reactivity in high titers has been seen. As such, quantitative titers cannot be used distinguish between a false-positive reaction and syphilis. To this end, careful and deliberate clinical evaluation of lab values and other evidence is requisite for proper diagnosis.

SCREENING

Recommendations for asymptomatic screening by population include:

▶ *MSM*

- At least annually if sexually active
- More frequently (eg, every 3 months) for persons with ongoing risk of infection or reinfection since last screened

▶ *Patients Taking PrEP for HIV Infection*

- At PrEP initiation
- Every 6 months for all patients on PrEP; every 3 months for MSM at high risk

▶ *Transgender Women and Men*

- Make an individualized assessment of STI/HIV-related risk and offer screening as appropriate for asymptomatic infections

▶ *Nonpregnant Women and Non-MSM Men*

- No national recommendations for routine screening in the general population
- Screening annually is recommended in sexually active persons who are at increased risk for infection

▶ *WSM*

- No national recommendations for routine screening in the general population

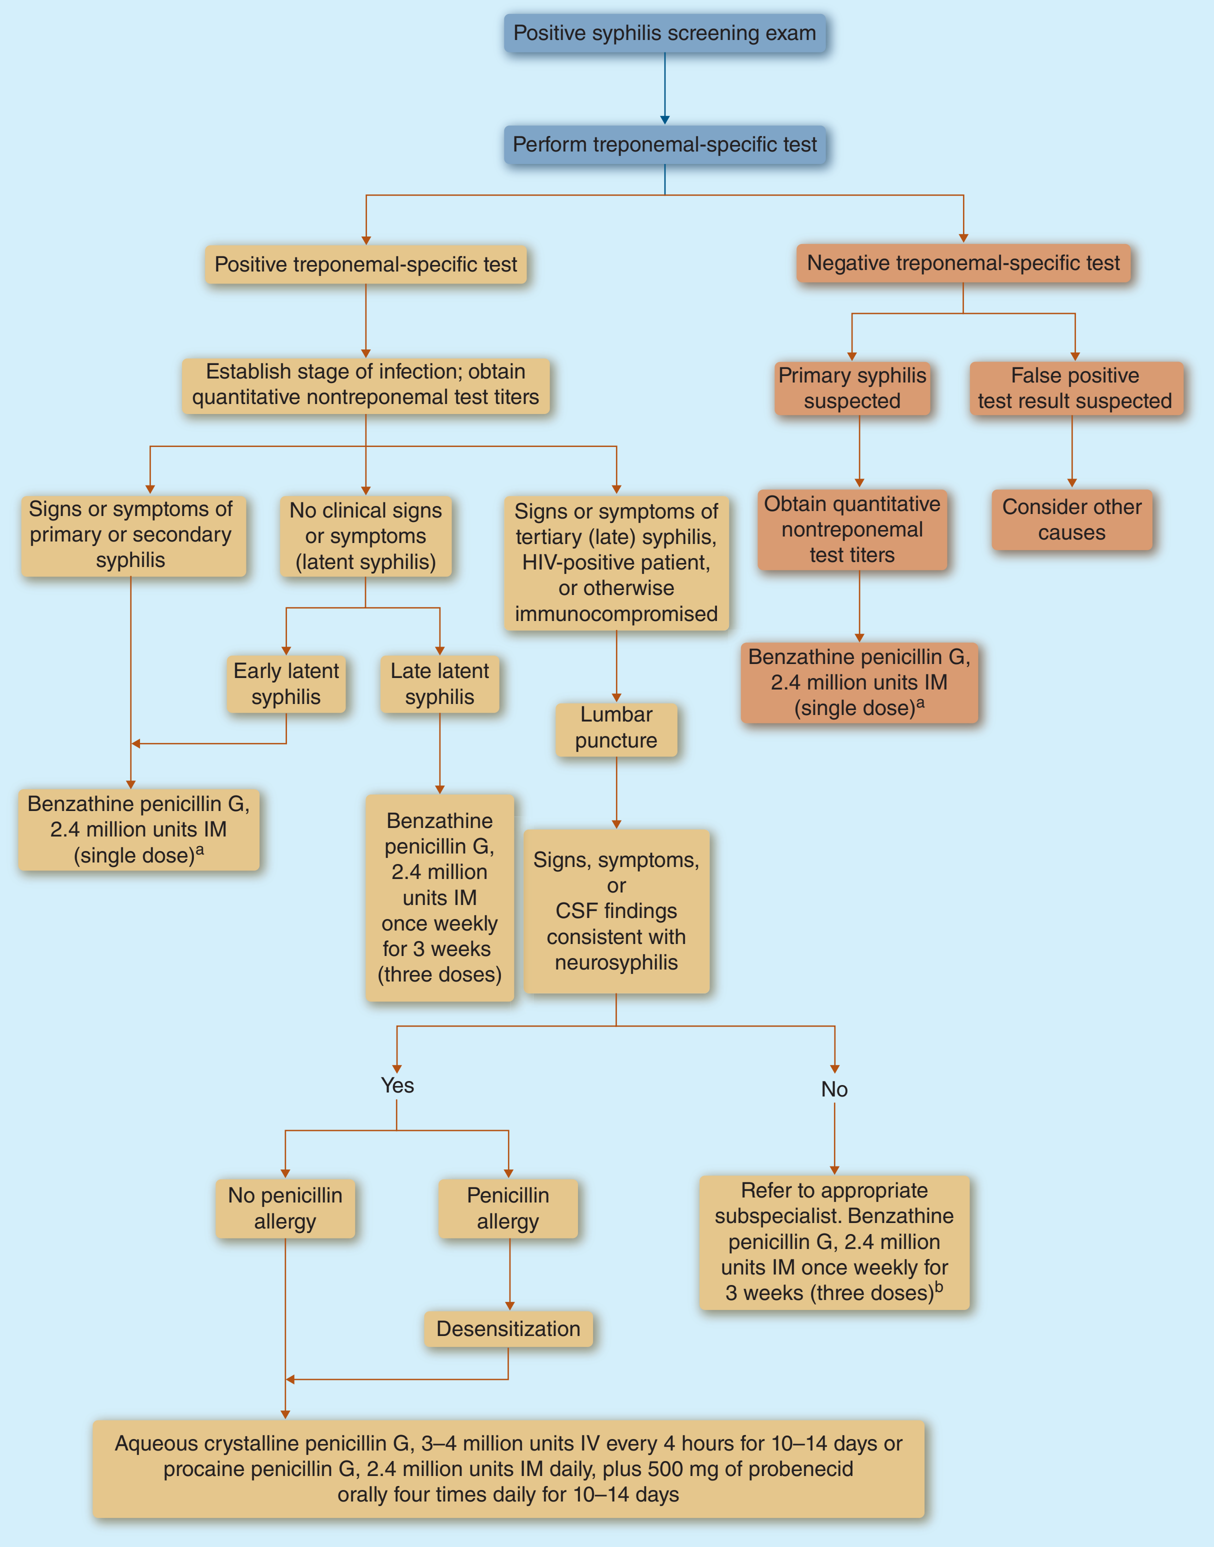
▶ *Pregnant Women*

- At first prenatal medical encounter
- At delivery (including live births, still births, or termination)
- At the time of fetal death, if applicable (after 20 weeks gestation)
- High-risk patients should be rescreened early in the third trimester (at approximately 28 weeks' gestation) and at delivery
- Assessment of sexual risk for syphilis at each prenatal visit
- Serologic rescreening if patient reports
    - New partner
    - Recent bacterial STI
    - Sex with MSM or transgender woman

TREATMENT

After confirming the diagnosis of syphilis, the desired outcome is a fourfold decrease in quantitative nontreponemal titers over a 6-month period and within 12 to 24 months after treatment of latent or late syphilis. An algorithm for the treatment of syphilis is shown in Figure 83–1.

With regard to neurosyphilis, a reduction in neurologic manifestations is desired, which may include seizures, paresis, meningitis, stroke, hyperreflexia, visual disturbances, hearing loss, neuropathy, or loss of bowel and bladder function. In late neurosyphilis, vascular lesions (meningovascular neurosyphilis) may also be observed; thus, a reduction in the number of observed lesions is warranted. A diminution in CSF white blood cell (WBC) (< 10 × 103/mm^3 [10 × 109/L]) or protein levels (0.05 g/dL [0.5 g/L]) is also preferred.



Positive syphilis screening exam
Perform treponemal-specific test
Positive treponemal-specific test
Negative treponemal-specific test
Establish stage of infection; obtain quantitative nontreponemal test titers
Primary syphilis suspected
False positive test result suspected
Signs or symptoms of primary or secondary syphilis
No clinical signs or symptoms (latent syphilis)
Signs or symptoms of tertiary (late) syphilis, HIV-positive patient, or otherwise immunocompromised
Obtain quantitative nontreponemal test titers
Consider other causes
Early latent syphilis
Late latent syphilis
Benzathine penicillin G, 2.4 million units IM (single dose)a
Lumbar puncture
Benzathine penicillin G, 2.4 million units IM (single dose)a
Benzathine penicillin G, 2.4 million units IM once weekly for 3 weeks (three doses)
Signs, symptoms, or CSF findings consistent with neurosyphilis
Yes
No
No penicillin allergy
Penicillin allergy
Refer to appropriate subspecialist. Benzathine penicillin G, 2.4 million units IM once weekly for 3 weeks (three doses)b
Desensitization
Aqueous crystalline penicillin G, 3–4 million units IV every 4 hours for 10–14 days or procaine penicillin G, 2.4 million units IM daily, plus 500 mg of probenecid orally four times daily for 10–14 days

FIGURE 83–1. Treatment of syphilis. [a]Alternative treatments for nonpregnant penicillin-allergic patients: doxycycline 100 mg PO twice daily for 2 weeks, or tetracycline 500 mg four times daily for 2 weeks; limited data support ceftriaxone 1 g once daily IM or IV for 8 to 10 days; or azithromycin, 2 g PO (single dose). [b]Alternative treatments for nonpregnant penicillin-allergic patients: doxycycline, 100 mg PO twice daily for 4 weeks, or tetracycline 500 mg PO four times daily for 4 weeks. Pharmacologic Therapy

KEY CONCEPT Parenterally administered penicillin is recommended for all stages of syphilis (Table 83–3).[9] Although penicillin is the drug of choice, combinations of benzathine penicillin with procaine penicillin or oral penicillin preparations are not considered appropriate treatment regimens. Several reports demonstrated the misuse of the benzathine–procaine combination (Bicillin C-R) instead of the standard benzathine penicillin (Bicillin L-A) for treatment of syphilis.[23] Clinicians and purchasing agents should be aware of the similarities in product names to avoid errors in the prescribing and administration of these agents. Pertinent information germane to penicillin G is found in Table 83–4.

Alternative agents may be used in allergic individuals and include doxycycline, minocycline, tetracycline, or erythromycin base or stearate. Some patients (such as young children or pregnant women) may not respond favorably to alternative modalities or should not receive tetracyclines.

Persons with a history of severe non-IgE-mediated reactions are not candidates for skin testing or challenge and should avoid penicillins indefinitely.[9] After employing a full battery of tests, persons who report an allergy and who are skin-test negative may receive penicillin. However, in those with a positive skin test, desensitization should be performed before beginning treatment. Desensitization refers to a process of giving a medication in a controlled and gradual manner, which allows the patient to tolerate a drug temporarily without an allergic reaction.

Patients may experience fever, chills, tachycardia, and tachypnea, a condition commonly known as the Jarisch–Herxheimer reaction, an acute febrile reaction accompanied by headache, myalgia, fever, and other symptoms within the first 24 hours after the initiation of therapy. This reaction is postulated to occur secondary to spirochete lysis and proinflammatory cytokine cascades. Treatment is supportive and may include antipyretic and anti-inflammatory agents, as well as fluid resuscitation and bed rest. Additionally, in most cases, treatment for the Jarisch–Herxheimer reaction does not require halting penicillin or pursuing alternate therapy.

OUTCOME EVALUATION

The CDC has provided patient care monitoring guidelines for syphilis (Figure 83–2).[9,12,20,23]

Primary and Secondary Syphilis

- After 6, 12, and 24 months of treatment, reexamine the patient and recommend a follow-up quantitative nontreponemal titer. More frequent assessment might be sensible if follow-up is uncertain. If the patient is asymptomatic and a fourfold increase in nontreponemal titer or persistent or recurrent symptoms are observed, order an HIV test and a lumbar puncture; if the patient is HIV-positive, suggest an infectious disease consult.
- In patients who are both negative for HIV and the lumbar puncture, administer benzathine penicillin G 2.4 million units IM once weekly for 3 additional weeks. Perform a patient follow-up in 6 months including a clinical examination and another nontreponemal titer. In HIV-negative patients with lumbar puncture findings compatible with neurosyphilis, treat the patient accordingly for neurosyphilis.
- Six months after the original diagnosis, institute a standard clinical follow-up examination in patients who show no symptomatology and a fourfold decrease in nontreponemal titers. By testing and observing the patient for signs of remission, you may be able to initiate proper treatment or recommend a consult in a timely fashion, thereby decreasing the propensity of the patient's condition to advance to a higher stage.
- If serologic titers do not decline despite a negative CSF examination and a repeated course of therapy, it is unclear whether additional therapy or CSF examinations are needed; additional testing or repeated therapy is not generally recommended.

Early and Late Latent Syphilis

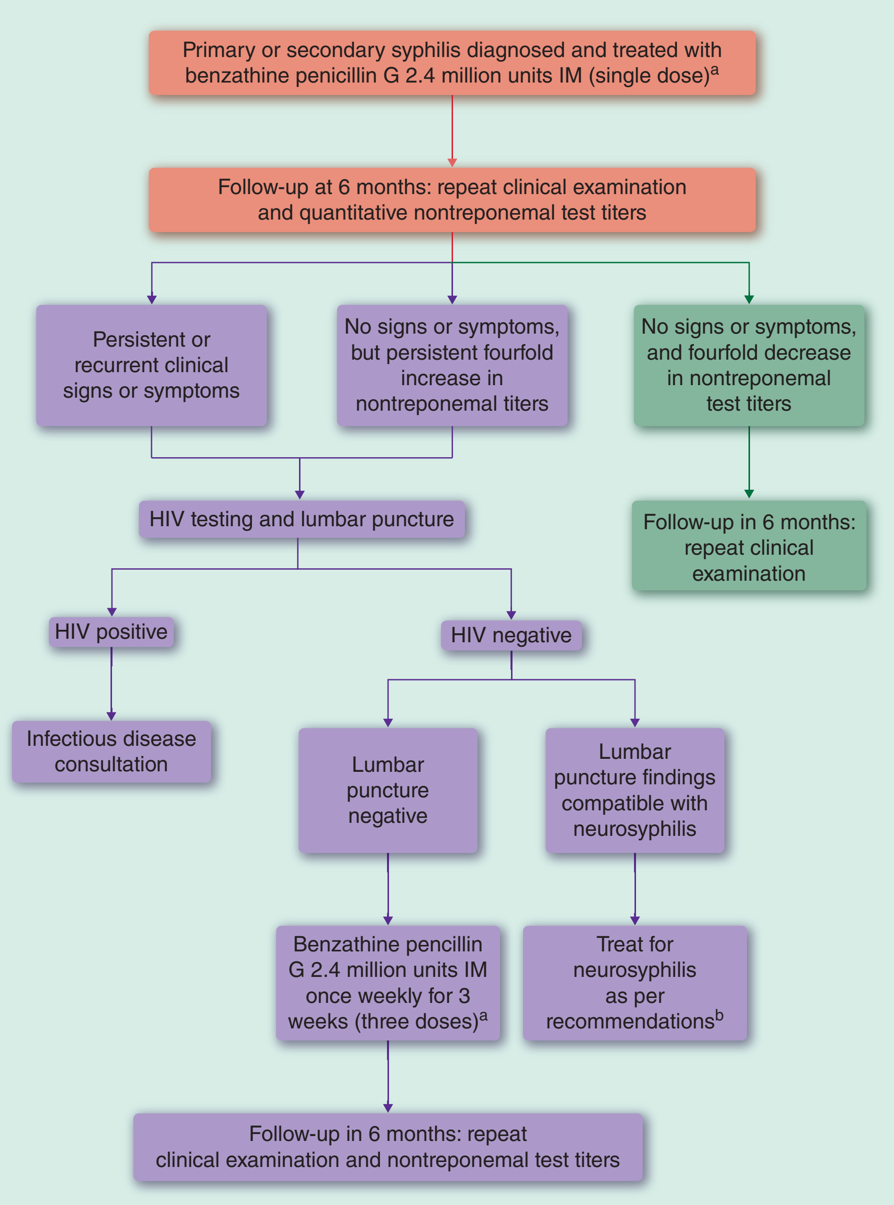
- Order nontreponemal titers 6, 12, and 24 months after instituting treatment for early or late latent syphilis.

Table 83–4

Treatment Recommendations for Syphilis

Indications	Drugs	Dose	Route	Duration	Alternative	Allergies
Primary Syphilis ***Adults*** ***Children***	Benzathine penicillin Benzathine penicillin	2.4 Million units 50,000 Units/kg, up to adult dose of 2.4 million units	IM IM	Single dose Single dose	Two injections of 1.2 million units as single doses Procaine penicillin 1.2 million units IM for 10–14 days Doxycycline 100 mg PO twice daily for 2 weeks Ceftriaxone 1 g IM daily for 10–14 days	Doxycycline 100 mg PO twice daily for 2 weeks
Secondary and Early Latent Syphilis (< 1-year duration) ***Adults*** ***Children***	Benzathine penicillin Benzathine penicillin	2.4 Million units 50,000 Units/kg, up to adult dose of 2.4 million units	IM IM	Single dose Single dose	Two injections of 1.2 million units as single doses Procaine penicillin 1.2 million units IM for 10–14 days Doxycycline 100 mg PO twice daily for 2 weeks Ceftriaxone 1 g IM daily for 10–14 days	Doxycycline 100 mg PO twice daily for 2 weeks
Late Latent Syphilis ***Adults*** ***Children***	Benzathine penicillin Benzathine penicillin	2.4 Million units 50,000 Units/kg, up to adult dose of 2.4 million units	IM IM	Once weekly for 3 weeks (total dose is 7.2 million units) Once weekly for 3 weeks (total dose 150,000 units/kg up to the adult dose of 7.2 million units)		
Tertiary Syphilis	Benzathine penicillin	2.4 Million units	IM	Once weekly for 3 weeks (total dose is 7.2 million units)	Doxycycline 100 mg PO twice daily for 4 weeks in nonpregnant patients Erythromycin 500 mg PO four times daily for 4 weeks may be used with caution in pregnant patients[23,24]	
Gummatous and Cardiovascular Syphilis	Benzathine penicillin (may be used as long as no evidence exists of CNS involvement)	2.4 Million units	IM	Once weekly for 3 weeks (total dose is 7.2 million units)	Doxycycline 100 mg PO twice daily for 4 weeks in nonpregnant patients Erythromycin 500 mg PO four times daily for 4 weeks may be used with caution in pregnant patients[23,24]	
Neurosyphilis	Penicillin G	3–4 Million units	IV	Every 4 hours for 10–14 days (may also be continuously infused) Benzathine penicillin 2.4 million units IM once weekly for up to 3 weeks may be used after intravenous therapy	Procaine penicillin 2.4 million units IM once daily, plus probenecid 500 mg four times daily, both for 10–14 days	
Congenital Syphilis	Benzathine penicillin	2.4 Million units	IM	Once weekly for 3 weeks (total dose is 7.2 million units)	Procaine penicillin 0.6–0.9 million units IM for 10–14 days Ceftriaxone 1 g IM or IV daily for 8–10 days	Asymptomatic neonates: 50,000 units/kg as a single IM dose Symptomatic neonates: 50,000 units/kg of aqueous crystalline every 12 hours IM for the first 7 days of life, then every 8 hours for 3 days or procaine penicillin G 50,000 IU/kg IM daily for 1015 days

Data from Refs. [9,24,25].



Primary or secondary syphilis diagnosed and treated with benzathine penicillin G 2.4 million units IM (single dose)a
Follow-up at 6 months: repeat clinical examination and quantitative nontreponemal test titers
Persistent or recurrent clinical signs or symptoms
No signs or symptoms, but persistent fourfold increase in nontreponemal titers
No signs or symptoms, and fourfold decrease in nontreponemal test titers
HIV testing and lumbar puncture
Follow-up in 6 months: repeat clinical examination
HIV positive
HIV negative
Infectious disease consultation
Lumbar puncture negative
Lumbar puncture findings compatible with neurosyphilis
Benzathine pencillin G 2.4 million units IM once weekly for 3 weeks (three doses)a
Treat for neurosyphilis as per recommendationsb
Follow-up in 6 months: repeat clinical examination and nontreponemal test titers

FIGURE 83–2. Patient care monitoring for syphilis. [a]See text for alternative treatment recommendations for nonpregnant penicillin-allergic patients. [b]See text for treatment recommendations for neurosyphilis. (Reprinted with permission from Diagnosis and Management of Syphilis, July 15, 2003, Vol. 68, No. 2, American Family Physician Copyright © 2003 American Academy of Family Physicians, All Rights Reserved.)

Neurosyphilis should be strongly considered in patients who show a fourfold increase in titers, patients who have an initially high titer (1:32 or greater) that fails to decline at least fourfold within 12 to 24 months of therapy, HIV-infected patients, and patients who develop signs or symptoms associated with neurosyphilis.[9,22,25]

Neurosyphilis

- Follow-up is dependent on the CSF findings. If pleocytosis is present, reexamine the CSF every 6 months until the WBC count normalizes. Consider recommending a second course of treatment if the CSF white count does not decline after 6 months or completely normalize after 2 years.[4,9,21] Failure to normalize may require retreatment; most treatment failures occur in immunocompromised patients.

Congenital Syphilis

- Observe the patient for changes in clinical features; hepatomegaly, jaundice, and bone changes will usually resolve in 3 months.[26]
- Monitor elevated serologic markers (nontreponemal tests) for reduction in titer levels. Given effective treatment, clinical features will usually disappear after 6 months. On this basis, evaluate seropositive infants periodically for at least 6 months.

TRICHOMONIASIS

Trichomoniasis is caused by the protozoan *Trichomonas vaginalis* and is far more prevalent than *C. trachomatis* or *N. gonorrhoeae*. In the United States, approximately 5 million new cases appear annually, compared with 3 million chlamydial and 650,000 gonococcal cases annually.[27] No vaccine exists for trichomoniasis.

Patient Encounter 2

WC, a 31-year-old Caucasian woman, walks into the clinic today complaining of a yellowish-green discharge along with a vaginal odor for the past several days. WC is a herbalist and vegetarian. WC does not believe in relational attachments and admits to having multiple sexual partners. Safe sex is always performed with new partners for the first 3 months states WC. She drinks a glass of red wine daily along with smoking medical marijuana for PTSD and indulges in other recreational drugs for entertainment.

What characteristics are indicative of trichomoniasis?

What would be the consequences of her daily alcohol consumption while taking metronidazole?

PATHOPHYSIOLOGY

T. vaginalis, a protozoa, may be isolated from the vagina, urethra, and Bartholin or Skene glands. After attachment to the host cells, it ignites an inflammatory response exhibited as a discharge containing elevated levels of polymorphonuclear leukocytes. The pathogen causes direct damage to the epithelium, leading to microulcerations.

CLINICAL PRESENTATION AND DIAGNOSIS

Diagnosis is usually performed with a wet mount or Papanicolaou smear. In women, symptoms are characterized by diffuse, malodorous, yellow-green vaginal discharge with vulvar irritation. Some women may be asymptomatic.

TREATMENT

The desired outcome is the complete eradication of *T. vaginalis* in both partners and elimination of the signs and symptoms observed.

Clinical Presentation of Trichomoniasis[9,27]

General

- Asymptomatic

Signs

- Strawberry cervix (women)
- Colpitis macularis (women)
- Prostatitis or epididymitis (men)

Symptoms

- Vaginal/vulvar erythema
- Excessive yellow-green discharge
- Vulvar itching
- Vaginal odor
- Urethral discharge or irritation
- Dysuria
- Vaginal pH greater than 4.5

Table 83–5

Treatment Recommendations for Trichomoniasis

Indications	Drugs	Dose	Route	Duration
Trichomoniasis	Metronidazole	2 g	PO	Single dose
	Tinidazole	500 mg	PO	Twice daily for 7 days
	Effective for metronidazole-resistant trichomoniasis	2 g	PO	Single dose

Data from Refs. [9,27,28].

Pharmacologic Therapy

KEY CONCEPT The 5-nitroimidazoles (metronidazole and tinidazole) have been the standard therapy for trichomoniasis for over 45 years. When using these agents, advise patients to avoid the consumption of alcohol. Pharmacologic treatment for trichomoniasis may be found in Table 83–5.[9,27,28]

▶ *Side Effects and Contraindications*

Metronidazole

Common side effects, which are gastrointestinal disturbances, are typically mild. Occasional adverse effects have also been reported, which include an unpleasant metallic taste, reversible neutropenia, urticaria, rash, flushing, dry mouth, darkened urine, and a disulfiram-like reaction.

Tinidazole

Tinidazole is associated with fewer side effects that metronidazole. Possible side effects include an unpleasant metallic taste, dizziness, loss of coordination, seizures, severe diarrhea, darkened urine, nausea, vomiting, and a swollen or discolored tongue.

Contraindications

Contraindications include hypersensitivity to nitroimidazole derivatives or any components of the formulation and use of disulfiram (past 2 weeks) or alcohol (within 3 days of therapy).

▶ *Allergies*

Patients who allergic to metronidazole should not be prescribed tinidazole.

▶ *Pregnancy*

Recommend a single 2-g dose of metronidazole, if treatment is deemed necessary. Retreatment of trichomoniasis during pregnancy may relieve symptoms of vaginal discharge or prevent the rare complication of neonatal respiratory infection with trichomoniasis. In breastfeeding women, the CDC recommends stopping breastfeeding during the course of metronidazole treatment and for 12 to 24 hours after the last day. For treatment with tinidazole, the CDC recommends stopping breastfeeding for the course of treatment and for 3 days after the last dose.

OUTCOME EVALUATION

- Order diagnostic test for trichomoniasis. If positive, recommend antibiotics that cover *T. vaginalis*.
- Subsequent to treatment, expect the eradication of the protozoa.

- Provide treatment for partner(s) to mitigate the probability of reinfection.
- Counsel patient on the significance of refraining from sex for 7 days after treatment.
- Rescreen patients 3 months after treatment, if there is a high probability of reinfection.

GENITAL WARTS

Genital warts, caused by the human papillomavirus (HPV), usually appear in the genital area (penis, vulva, vagina, cervix, perineum, and perianal area) as very contagious, small bumps. Responsible for various visible, keratotic, and nonkeratotic manifestations, HPV has more than 150 noted strains, some of which have been linked to squamous cell carcinoma.[29] More than 60 strains have been linked to the genital area.[30] Two general categories of genital HPV exist as low-risk benign HPV lesions and high-risk neoplastic HPV lesions. The low-risk strains are responsible for genital warts and low-grade cervical lesions.[31]

EPIDEMIOLOGY AND ETIOLOGY

Genital warts are caused by several strains of HPV and spread by skin-to-skin contact (ie, vaginal, anal, or oral) during sexual activity with an infected person.[31,32] HPV can be passed when an infected person has no signs or symptoms. Affecting over 79 million Americans, HPV is the most common, newly diagnosed STI in the United States, with prevalence of approximately 52%. Almost 14 million new HPV infections occur every year in the United States.[29] Nearly half of new infections occur among persons aged 15 to 24 years. Condoms offer incomplete (grade B, level II [fair research-based evidence to support the recommendation]) protection against HPV because HPV can infect areas not covered by a condom.[31,32]

The greatest incidence of HPV was noticed in men with three or more sex partners and women whose most recent regular sexual partner had two or more lifetime partners. Smoking, an uncircumcised male, being immunocompromised, oral contraceptives, and early coital age are also risk factors for acquiring genital warts. Most people with HPV do not develop symptoms. At least half of sexually active persons will become infected at least once in their lifetime. In 90% of the cases, the body immune system clears HPV naturally within 2 years. Routine testing of HPV DNA infection is not recommended because test results would not alter clinical management of the condition. **KEY CONCEPT** HPV types 16 and 18 cause 99.7% of all cervical cancer while HPV types 6 and 11 are responsible for about 90% of genital and perianal warts.[31,33]

PATHOPHYSIOLOGY

HPV invades cells of the basal layer of the epidermis, penetrating skin, and mucosal microabrasions in the genital area. A latency period of 3 weeks to 9 months may ensue. Following that period, viral DNA, capsids, and particles are produced. Host cells become infected and develop the morphologic atypical koilocytosis of genital warts.[31,34] Genital warts are the clinical manifestation of active viral replication and virion production at the infection site.

CLINICAL PRESENTATION AND DIAGNOSIS

- A definitive diagnosis of HPV is based on DNA, RNA, or capsid protein detection.
- Diagnosis is generally made from the clinical presentation or by visual inspection. It may be classified into several categories: classic condyloma acuminata, which are pointed or cauliform; keratotic warts with a thick, horny surface resembling common skin warts and flat warts, which are frequently observed on the surface.
- Tissue biopsy or viral typing is only indicated if the diagnosis is uncertain and is not recommended for patients with routine or typical lesions.
- Since HPV is highly associated with cervical cancer and has more than 20 different cancer-associated HPV types, patients who are diagnosed with HPV should be tested for cervical cancer.

Clinical Presentation of Genital Warts[9,34]

General

- Appear as rough, thick, cauliflower-like lesions

Signs

- Black dots within warts
- Disrupted surface

Symptoms

- Anogenital pruritus
- Burning
- Vaginal discharge or bleeding
- Although rare, dyspareunia may occur with vulvovaginal condyloma

TREATMENT

The most reliable method to avoid genital warts is to abstain from sexual activity.[9] Genital warts are usually asymptomatic but can be painful or pruritic. Approximately 40% to 60% of untreated warts will spontaneously resolve in 9 to 12 months if left untreated.[31] Treatment of benign, symptomatic genital warts is aimed at alleviation of physical symptoms and cosmetic improvement. Removal of visible warts and reduction of infectivity are the goals of treatment. Many cases of genital warts fail to respond to treatment or recur after adequate response.[31]

A comparison of adverse effects related to treatment options may be found in Table 83–6.

Patient-Applied Treatment

▶ *Podofilox*

- 0.5% gel or solution
- Podofilox inhibits the formation of the mitotic spindle and prevents cell division
- Surface area treated must not exceed 10 cm^2
- Apply solution (using a cotton swab) or gel (using a finger) twice daily for 3 consecutive days, followed by 4 consecutive days without treatment. This cycle may be repeated until there are no visible warts for a maximum of 4 weeks.

▶ *Imiquimod*

- 3.75% or 5% topical cream in single-dose application packets
- Imiquimod is a cell-mediated immune-response modifier

Table 83–6

Comparison of Adverse Effects Seen With Treatments for Genital Warts

Treatment	Adverse Effects
Podofilox	Burning at site of application, pain, inflammation
Imiquimod	Erythema, irritation, ulceration, pain, burning, edema, pigmentary changes
Sinecatechins	Burning at site of application, erythema, pruritus, edema
Podophyllin resin	Local irritation, erythema, burning, soreness at application site; possibly oncogenic
Bichloroacetic and trichloroacetic acid	Local irritation and pain, minimal systemic effects
Cryotherapy	Pain or blisters at application site
Surgical excision	Pain, bleeding, scarring; possible burning or allergic reaction to local anesthetic
Vaporization	Pain, bleeding, scarring; risk of HPV spreading via smoke plumes
Intralesional interferon	Burning, itching, irritation at injection site, systemic myalgia, headache, fever, chills, leukopenia, elevated liver enzymes, and thrombocytopenia

HPV, human papillomavirus.

Data from Refs. [9,31,35].

- There are two recommended dosage regimens:
  a. Apply 5% cream at bedtime, three times a week for up to 16 weeks or every other day for three applications.
  b. Apply 3.75% cream applied once at bedtime.

The treatment area should be washed with soap and water 6 to 10 hours after application. Mild-to-moderate erythema has been noted with imiquimod use; however, this generally suggests that the drug is reaching a therapeutic range and clearing the lesion.[9]

▶ *Sinecatechins*

- A total 15% of the ointment is green tea extract with an active product catechins
- Apply a thin layer (0.5 cm) using a finger to each wart three times a day until complete clearance of warts.
- Do not wash off after use, and all sexual contact should be avoided while ointment is on the skin
- This product should not be continued for longer than 16 weeks.[9]
- The safety of sinecatechins during pregnancy is unknown.

Physician-Applied Treatments

▶ *Podophyllin Resin*

- A 10% to 25% solution of podophyllin resin in a compound tincture of benzoin has been the standard in-office treatment for genital warts.
- Because podophyllin is neurotoxic and systemically absorbed, only a small amount (no > 0.5 mL) should be applied.
- Application should be limited to less than 0.5 mL of podophyllin on an area of less than 10 cm^2 of warts per session and no open lesions or wounds should exist in the area to which treatment is administered.[9,31]
- Topical podophyllin is applied once weekly and the area should be allowed to dry. Immediately following treatment, the dried drug should be removed using alcohol or soap and water.
- Topical podophyllin is contraindicated in pregnant patients.

▶ *Bichloroacetic (BCA) and Trichloroacetic (TCA) Acids*

- They are in 80% to 90% concentrations and are not systemically absorbed
- These caustic agents destroy warts by chemical coagulation of proteins
- The products are effective when used to treat a few small, moist lesions
- Apply once a week until the wart is resolved
- May be used in pregnancy

To avoid these adverse effects, place petroleum jelly around the external lesion, including unaffected skin, and carefully apply the agent with a small applicator.

▶ *Other Treatments*

Other treatments may include fluorouracil/epinephrine/bovine collagen gel, an intralesional injection that has been proven effective in clinical trials for refractory patients or an intralesional injection of interferon.[34,35]

Ablative Therapy

Several ablative options have been employed in the treatment of genital warts and include cryotherapy with liquid nitrogen or cryoprobe, surgical removal by excision, and vaporization. Cryotherapy destroys warts by thermal-induced cytolysis. Use an open spray or cotton-tipped applicator for 10 to 15 seconds and repeat, as needed. Wart clearance occurs about 75% of the time. Pain during and after application of the liquid nitrogen, followed by necrosis and sometimes blistering is common.[9]

Special Therapeutic Issues[9,31]

▶ *Large Warts*

Treat warts greater than 10 mm in diameter with surgical excision, carbon dioxide (CO_2) laser, or by curettage.[30] Use imiquimod for three to four treatment cycles to reduce the number of warts and improve surgical outcomes. Fifty percent reduction in wart size after four treatment cycles warrants continued use of imiquimod until warts clear or eight cycles have been completed; less than 50% reduction warrants surgical excision or other ablative therapy.

▶ *Subclinical Warts*

Subclinical warts may be identified through colonoscopy, biopsy, acetic acid application, or laboratory serology. However, early treatment has not been linked to a favorable effect during the course of therapy in the index patient or the partner with regard to reduction of the transmission rate.

▶ *Pregnancy*

Agents contraindicated in pregnancy include podofilox, sinecatechins, fluorouracil, and podophyllin. Imiquimod is not approved for use in pregnancy, although it has been considered after signed consent has been obtained. Bichloroacetic and trichloroacetic acids have been used without problems. Ablative therapy is also a viable option.

OUTCOME EVALUATION

- Monitor the patient for any visible warts and relief of symptoms.
- Apply powder with talc, baking soda, or liquid soap to remove unreacted trichloracetic or bichloroacetic acid.
- Dry area before contact with normal mucosa after application of podophyllin.
- Repeat TCA, BCA, podophyllin treatment weekly if necessary.
- Administer a different agent if warts persist after one type of therapy.
- Refer all recalcitrant patients to local STI clinics, gynecologists, dermatologists, or urologists.

VACCINES AND TOXOIDS

Thirteen HPV types (33, 35, 39, 40, 43, 45, 51–56, 58) have moderate risk for neoplastic conversion.[31] Several HPV genotypes have been linked to the development of cervical cancer. Gardasil, a quadrivalent vaccine (4vHPV) developed to protect against HPV genotypes 6, 11, 16, and 18, was the first vaccine employed to prevent cervical cancer, precancerous genital lesions, and genital warts due to HPV. Cervarix, a bivalent vaccine (2vHPV), prevents cervical cancer and precancers caused by HPV types 16 and 18. Both Gardasil (4vHPV) and Cervarix (2vHPV) were discontinued in the United States in October 2016. Gardasil 9, a 9-valent vaccine, protects against infection with HPV types 6, 11, 16, 18, 31, 33, 45, 52, and 58.

The CDC recommends the HPV vaccine for all 11- and 12-year-old girls and boys (may start at age 9). Vaccination is also recommended for females aged 13 through 26 years and males 13 to 21 years old who have not been previously vaccinated or who have not completed the full series of shots.[29,33] In the past, inactivated vaccines were given in a series of three IM injections over a 6-month period. Second and third doses were given at 2 and 6 months, respectively, after the first dose. However, the CDC guidelines now recommend that 11- to 12-year-olds receive two doses of the HPV vaccine, rather than the previously mentioned three doses. The second dose should be given 6 to 12 months after the first. HPV vaccine may be given at the same time as other vaccines.

In June 2019, the Advisory Committee on Immunization Practices (ACIP) recommended shared clinical decision-making for HPV vaccination of adults aged 27 to 45 years.

HPV vaccines are very safe and efficacious in preventing genital warts; however, they will not clear those that are already present. Either vaccine is recommended for girls/women, whereas only one vaccine (Gardasil) is recommended for boys/men.[29] In adults up to 45 years old with HPV, Gardasil was 88% effective in preventing genital warts and precancerous lesions.[31,35,36]

HPV vaccine is not recommended for use during pregnancy.[29]

GENITAL HERPES

Genital herpes (GH) is caused by herpes simplex virus (HSV) types 1 and 2. HSV is a chronic, ubiquitous, lifelong viral infection, for which there is no cure. Once latency is established, neither competent host immunity nor therapeutic agents can eradicate the virus.[9] Currently, there is no vaccine available for HSV, and it seems that the development of one is unlikely in the near future. HSV-1 is mainly transmitted by oral-to-oral contact to cause oral herpes (cold sores) but can also cause GH through oral sex. HSV-2 is an STI that causes GH.[37]

Clinical Presentation of Genital Herpes[9,37,38]

General

- Asymptomatic

Classic Sign

- A cluster of painful vesicles on an erythematous base

Symptoms

- Itching
- Burning
- Tingling
- Groin lump
- Dysuria
- Dyspareunia
- Increased urinary frequency

Other Symptoms

- Ulcerative lesions, fissures, cervicitis

EPIDEMIOLOGY AND ETIOLOGY

Approximately 50 million Americans have GH. HSV-2 is the most common cause of recurrent GH. Roughly one in six people in the United States (16.2%) aged 14 to 49 is infected with HSV-2, with over 500,000 new cases of HSV-2 occurring annually.[9] Most HSV-1 infections are acquired during childhood. Many persons infected with HSV-2 have not been diagnosed; therefore, most GH infections are transmitted by persons unaware of their status.[37]

PATHOPHYSIOLOGY

HSV can cause primary or reactivation (recurrent) infections. Since HSV is only found in humans, infection may only be transmitted from infectious secretions onto mucosal surfaces (ie, cervix or urethra) or direct contact with an active lesion (abraded skin). The virus may survive for a limited amount of time on environmental surfaces. **KEY CONCEPT** Nearly all HSV-2 infections are sexually acquired. Most sexual transmission occurs while the source case is asymptomatic. Most patients with unrecognized genital HSV infections will still shed virus intermittently in the genital tract. Patients will have small, painful blisters that are filled with fluid. The first outbreak takes 2 to 4 weeks to heal. Because there is no cure for this illness, treatment will only help reduce the signs, symptoms, and number of attacks.[9] Persons with GH should be tested for HIV infection because of their epidemiological synergy.[37] The severity and frequency of the disease and the recurrence rate depends on numerous factors including viral type, gender, and immune status of host. Recurrent infections are typically milder and shorter.[37,38]

CLINICAL PRESENTATION AND DIAGNOSIS

There are several methods by which a definitive diagnosis of HSV may be acquired, including virologic typing, serologic diagnosis, rapid point-of-care antigen detection, ELISA, immunoblot, and DNA polymerase chain reaction.[38] Glycoprotein G-based assays may also be used to aid in the diagnosis of HSV. Ulcerative or multiple vesicular lesions are absent in many infected persons.

Laboratory confirmation is vital to effective treatment, especially in individuals in whom a clinical diagnosis cannot be obtained.

TREATMENT

The virus is very evasive and can lay dormant for many years before infecting a person. Management of genital HSV should address the chronic nature of the disease rather than focusing solely on treatment of acute episodes of genital lesions. The desired outcome is to curtail the number of episodic prodromes and to minimize any side effects experienced due to the antivirals. Counseling of infected persons and their partners is vital to the management of HSV.

First Episode

The first episode is a systemic illness associated with the vesicular lesions, may last up to 21 days, usually has an uncomplicated course of infection and, in severe cases, may require hospitalization. This initial presentation occurs 4 to 7 days after sexual exposure. Several agents are effective during this period (Table 83–7).[37,38]

At the cited dosages, these agents produce excellent outcomes with regard to lesion healing time, viral shedding, and reduction in pain. Common adverse effects are nausea, headache, and diarrhea. It is important to note that the first episode does not necessarily indicate recent infection and the genital symptoms may develop several years after the infection was acquired. Condom use in new or uninfected partners, particularly in the 12 months after the first attack, is recommended.

Episodic Therapy

In a patient with a previous diagnosis of GH, the appearance of new vesicular lesions is synonymous with HSV reactivation. For most patients, GH recurrence is self-limiting and short-lived, lasting approximately 6 to 7 days.

Suppressive Therapy

Suppressive therapy is effective for controlling all symptoms related to the disease and may impact troublesome complications of infection. Before beginning suppressive therapy, discuss

Table 83–7

Comparison of Antiviral Agents Used for Herpes Simplex Infection

Agent	Dose	Side Effects
First Episode		
Acyclovir	*200 mg PO five times a day × 7–10 days* ***or*** 400 mg PO three times daily × 7–10 days	Headache, confusion, nausea, vomiting, thrombocytopenia, renal insufficiency, rash, pruritus, fever, arthralgias, myalgia, thrombotic thrombocytopenic purpura, hallucinations, somnolence, depression
Valacyclovir	*1 g PO two times daily × 7–10 days*	Refer to acyclovir
Famciclovir	250 mg PO three times daily × 7–10 days	Refer to acyclovir
Episodic		
Acyclovir	*200 mg PO five times daily × 5 days* ***or*** 400 mg PO every 8 hours × 5 days ***or*** 800 mg PO two times daily × 5 days ***or*** 800 mg PO three times daily × 2 days	Refer to acyclovir (WHO)
Valacyclovir	*500 mg PO two times daily × 3 days* ***or*** 1 g PO once daily × 5 days	Refer to acyclovir
Famciclovir	125 mg PO two times daily × 5 days ***or*** 1000 mg PO twice daily × 1 day	Refer to acyclovir
Suppressive		
Acyclovir	400 mg PO two times daily continuously ***or***	Refer to acyclovir
Valacyclovir	500 mg PO once daily continuously ***or***	Less effective if > 10 episodes per year
Valacyclovir	1000 mg PO once daily continuously ***or***	Refer to acyclovir
Famciclovir	250 mg PO two times daily continuously	Refer to acyclovir
Reserved Agents		
Foscarnet	40 mg/kg IV every 8 hours until clinical resolution is attained	Renal insufficiency, metabolic disturbances, hypophosphatemia
Cidofovir	1% topical agent (gel) used daily on a compassionate basis for acyclovir-resistant herpes lesions for 5 days	Application site reactions, lesion recrudescence
Imiquimod	Topical alternative used daily on a compassionate basis for acyclovir-resistant herpes lesions for 5 days	Application site reactions, lesion recrudescence

Italicized data indicate preferred dosages.

Data from Refs. [9,37].

patient expectations. Encourage patients to record any breakthrough episodes, as this may require treatment reevaluation and adjustment.

Preventive Therapy

Valacyclovir 500 mg PO once daily has been used to prevent the sexual transmission of HSV to an uninfected partner. In addition to pharmacologic therapy, counsel patients regarding safe sex practices.

Drug Resistance

All acyclovir-resistant strains are resistant to valacyclovir and the majority are resistant to famciclovir. Foscarnet, cidofovir, and trifluridine have been administered in acyclovir-resistant patients.[36] These agents are usually reserved for use after other medications have failed because of their associated toxicities.

Pregnancy

Women who are pregnant may transmit the virus to the neonate during delivery. There are two management strategies: caesarean section and antiviral therapy. Acyclovir 200 to 400 mg every 8 hours has been administered from 38 weeks' gestation until delivery. Acyclovir, famciclovir, and valacyclovir are all classified as category B (no evidence of risk in humans) for use during pregnancy. Suppressive treatment includes the use of acyclovir or valacyclovir from week 36 until delivery. The goal of therapy is to reduce the number of lesions and asymptomatic shedding at delivery.

Neonates

The risk for transmission from an infected mother to a neonate is highest among women who acquired GH near time of delivery.[39,40] Women who have GH prior to pregnancy are at very low risk of transmitting HSV to their infants. HSV infections should be considered in all neonates who present with nonspecific symptoms such as fever, poor feeding, lethargy, or seizures in the first month of life. Infants suspected to have or who are diagnosed with an HSV infection should be treated parenterally. Acyclovir 20 mg/kg/day in three divided doses IV for 21 days for disseminated and CNS disease *or* 14 days for disease limited to skin, eyes, and mucous membranes.

HIV Infection

Lesions caused by HSV are common among persons with HIV infection due to increased shedding. Affected individuals may have prolonged episodes of GH. Oral antiviral agents are effective in decreasing the clinical manifestations of HSV among those infected with HIV.[9,39]

OUTCOME EVALUATION

- Monitor for systemic symptom improvement and a decrease in viral shedding when initiating HSV treatment.
- Take lukewarm baths three to four times a day to ease itching and pain. Pat dry affected areas.
- Wear loose-fitting underwear to help the sore dry.
- Avoid sexual contact until treatment is finished.
- Consider stopping suppressive therapy after 1 year to assess recurrence rate.
- Compound topical 1% cidofovir gel in acyclovir-resistant strains where IV foscarnet is not preferred.

PELVIC INFLAMMATORY DISEASE

Pelvic inflammatory disease (PID) usually affects young, menstruating, sexually active women. PID includes a spectrum of inflammatory disorders of the upper female genital tract. In the majority of cases, the pathogens responsible are *C. trachomatis* and *N. gonorrhoeae*; although anaerobes, enteric Gram-negative rods and cytomegalovirus have also been implicated in the pathogenesis.[41] PID has been correlated with ectopic pregnancy, infertility, tubo-ovarian abscess, and chronic pelvic pain.[42] Currently, no vaccine exist for the treatment of PID despite ongoing efforts.

EPIDEMIOLOGY AND ETIOLOGY

PID is most common in minority women younger than 25 years of age, who have more than one sex partner and does not use contraception. PID leads to approximately 2.5 million office visits each year in the United States that cause 125,000 to 150,000 hospitalizations. The highest rates of PID occur in teenagers and first-time mothers. Up to 10% to 20% of untreated chlamydia or gonorrhea infections progress to PID and affected women may become infertile as a result.[9] Since many cases of PID are asymptomatic or inadequately treated, the potential for damage to reproductive health is increased. Additionally, there is an elevated risk for women with past STIs and for those who have more than one partner. However, over the past decade, evidence suggests a decline in PID diagnoses in the United States.[42]

PATHOPHYSIOLOGY

PID is an infection that occurs when bacteria traverses from a woman's vagina to her reproductive organs, including the uterus, fallopian tubes, and adjacent pelvic structures. Normally, the cervix prevents bacteria from spreading to the reproductive organs. However, when the cervix is exposed to STIs due to unprotected sex, bacteria may be disseminated into female internal organs. Less commonly, bacteria can enter the reproductive tract during menstruation, after childbirth, or abortion. Chlamydia, the primary organism associated with PID in the United States, may produce a heat-shock protein that causes tissue damage through a delayed hypersensitivity reaction. *C. trachomatis* may also possess DNA evidence of toxin-like genes that code for high-molecular-weight proteins with structures similar to *Clostridium difficile* cytotoxins, enabling inhibition of immune activation. This may explain the observation of a chronic chlamydia infection in subclinical PID.[43]

Patient Encounter 3

TS decided against medical treatment and utilized a herbalist to treat her chlamydia. The alternate treatment did not work, and intercourse became painful. TS was evaluated today by her primary physician due to a fever of 101°F and lower abdominal pain.

Given this additional information, what is suggestive of PID?

Identify treatment goals for this patient

Identify monitoring parameters of the antibiotics doxycycline and metronidazole used in her treatment.

Clinical Presentation of Pelvic Inflammatory Disease[9,41]

General

- Signs and symptoms may vary from mild to severe.

Signs

- Vague

Symptoms

- Lower abdominal or pelvic pain
- Malodorous vaginal discharge
- Abnormal uterine bleeding
- Dyspareunia
- Dysuria
- Nausea and/or vomiting
- Fever

CLINICAL PRESENTATION AND DIAGNOSIS[41,42]

Because many women with PID have subtle symptoms, delays in diagnosis and treatment may lead to inflammatory sequelae in the upper reproductive tract. Women who receive a diagnosis of acute PID should be tested for HIV, gonorrhea, and chlamydia. Because of the lack of severity in the symptoms for PID, protection of female fertility takes precedence in the diagnosis. Patients with uterine or cervical motion tenderness, painful urination, lower abdominal pain, painful intercourse, abnormal uterine bleeding (especially during or after intercourse), and adnexal tenderness with no other cause of these signs warrant treatment. Additional criteria include:

- Oral temperature greater than 38.3°C (101°F)
- Abnormal cervical or vaginal discharge which has an unusual color (green or yellow)
- WBC presence on saline microscopy of vaginal secretions
- Elevated erythrocyte sedimentation rate
- Elevated C-reactive protein
- Laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis*

TREATMENT

Presumptive treatment of PID should be initiated in young, sexually active women if they are experiencing pelvic or lower abdominal pain with one or more of the minimum clinical criteria present on the pelvic examination. KEY CONCEPT The removal of causative bacteria and reduction of any related sequelae are the desired goals of treatment. Bacteria that travel into the fallopian tubes can lead to inflammation, which causes scar tissue to form. This scar tissue can create blockages in the tubes and make it harder for sperm to fertilize an egg. Resolution of infection (ie, *N. gonorrhoeae, C. trachomatis*, *Streptococcus* spp., and Gram-negative facultative bacteria) and mitigation of sequelae should be the main goal of pharmacologic therapy. Treatment regimens for PID must provide empiric, broad-spectrum coverage of likely pathogens. Parenteral and oral regimens appear to have similar efficacy in women with PID of mild or moderate clinical severity. CDC-approved treatment regimens are shown in Table 83–8.[9,41]

Table 83–8

Treatment Regimens for Pelvic Inflammatory Disease

Parenteral Option A

Cefotetan 2 g IV every 12 hours (active against both aerobic and anaerobic Gram-positive and Gram-negative microorganisms) plus doxycycline 100 mg PO or IV every 12 hours (treatment of Gram ± bacteria, aerobes, and anaerobes)

or

Cefoxitin 2 g IV every 6 hours (active against Gram-negative bacteria and anaerobes) plus doxycycline 100 mg PO or IV every 12 hours

Parenteral Option B

Clindamycin 900 mg IV every 8 hours (treatment of anaerobic bacteria, Gram + cocci, and Gram ± bacilli) plus gentamicin, loading dose IV or IM (2 mg/kg) followed by maintenance dose (1.5 mg/kg) every 8 hours. A single daily dose of gentamicin (3–5 mg/kg) may be used (treatment of Gram ± bacteria, aerobes, and anaerobes)

Alternative Parenteral Treatment

Ampicillin–sulbactam 3 g IV every 6 hours (treatment of Gram + organisms) plus doxycycline 100 mg PO or IV every 12 hours

Oral

Ceftriaxone 250 mg intramuscular single dose (broader and stronger Gram-negative coverage and multiresistant enterobacteriaceae) plus doxycycline 100 mg PO twice daily for 14 days with or without metronidazole 500 mg PO twice daily for 14 days (treatment of various anaerobic organisms and trichomoniasis)

or

Cefoxitin 2 g intramuscular single dose and probenecid 1 g single dose, plus doxycycline 100 mg PO twice daily for 14 days with or without metronidazole 500 mg PO twice daily for 14 days

or

Third-generation cephalosporin (ceftizoxime or cefotaxime) (treatment of aerobic and anaerobic Gram ± organisms) plus doxycycline 100 mg PO twice daily for 14 days with or without metronidazole 500 mg PO twice daily for 14 days

Data from Refs. [9,41,42].

Though outpatient management remains contentious, many feel that outpatient management should be limited to individuals who remain afebrile, tolerate oral nourishment, or have a WBC counts less than 11 × 103/mm^3 (11 × 109/L), minimal evidence of peritonitis, or active bowel sounds. Nonetheless, outpatient therapy with a parenteral cephalosporin followed by doxycycline and metronidazole is recommended.

OUTCOME EVALUATION

- Reevaluate any patient who does not respond significantly within 72 hours of parenteral/oral treatment.
- Initiate parenteral therapy (inpatient or outpatient) for patients who do not respond to oral treatment.
- Continue parenteral therapy for 14 days; however, it may be discontinued 24 hours after clinical improvement. Doxycycline should be prescribed to complete 14 days of therapy.
- Hospitalization and reassessment of the antimicrobial regimen and diagnostics are recommended in women without clinical improvement.
- Repeat testing of all women who have been diagnosed with chlamydia or gonorrhea is recommended 3 to 6 months

after treatment, regardless of whether their sex partners were treated.

- Inform the patient that an alteration in sexual behavior should be the first concern, as high-risk sexual activity augments the probability of infection.

Abstinence is the best course of action, especially in patients with herpes during lesional episodes. However, compliance in some may be minimal, in which case, appropriate condom use should always be recommended. To alleviate any possible misconceptions about condom application, either demonstrate how to apply a condom or ask the patient to demonstrate. During the demonstration, explicitly educate the patient with regard to application, storage, and the use of lubricants.[43,44] Additionally, a woman's sexual partner(s) should be treated to decrease the risk of reinfection, even if the partner(s) has no symptoms.

Abbreviations Introduced in This Chapter

CSF	Cerebrospinal fluid
ELISA	Enzyme-linked immunosorbent assay
GH	Genital herpes
HPV	Human papillomavirus
HSV	Herpes simplex virus
L-A	Long acting
MSM	Men who have sex with men
PID	Pelvic inflammatory disease
RPR	Rapid plasma reagent
STI	Sexually transmitted infection
WSW	Women who have sex with women

Sepsis and Septic Shock

Trisha N. Branan, Susan E. Smith, and
Christopher M. Bland

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Compare and contrast the definitions of syndromes related to sepsis.
2. Identify the pathogens associated with sepsis.
3. Discuss the pathophysiology of sepsis as it relates to systemic inflammation, coagulation, and tissue hypoperfusion.
4. Identify patient symptoms as early or late sepsis and evaluate diagnostic and laboratory tests for patient treatment and monitoring.
5. Assess complications of sepsis syndromes and discuss their impact on patient outcomes.
6. Design desired treatment outcomes for septic patients.
7. Formulate a treatment and monitoring plan (pharmacologic and nonpharmacologic) for septic patients.
8. Evaluate patient response and devise alternative treatment regimens for nonresponding septic patients.

INTRODUCTION

KEY CONCEPT Sepsis occurs across a continuum of physiologic stages in response to infection, which manifests as systemic inflammation, coagulation, and tissue hypoperfusion, potentially leading to organ dysfunction.[1] The Third International Consensus Definitions for Sepsis and Septic Shock define sepsis as a life-threatening organ dysfunction caused by a dysregulated host response represented by an increase of at least 2 points in the Sequential (Sepsis-related) Organ Failure Assessment (SOFA) score (Table 84–1). Septic shock is defined as a subset of patients with further increases in mortality resulting from underlying circulatory, cellular, and/or metabolic abnormalities. These patients require the use of vasopressor support in addition to adequate volume resuscitation to maintain a mean arterial pressure (MAP) of at least 65 mm Hg and have an elevated serum lactate level greater than 2 mmol/L. Adult patients with suspected sepsis may be screened using a bedside clinical scoring system known as the quickSOFA (qSOFA) to rapidly identify patients who may need further diagnostic workup and intervention (Table 84–2).[2,3]

EPIDEMIOLOGY AND ETIOLOGY

Sepsis is the leading cause of morbidity and mortality for critically ill patients and the 10th leading cause of death overall.[4,5] Mortality rates remain high for patients with sepsis and septic shock, with septic shock and multiorgan failure as the most common causes of death.[1] Annually, there are approximately 1.7 million adults who develop sepsis in the United States with nearly 270,000 deaths.[6]

Risk factors for developing sepsis include increased age, cancer, immunodeficiency, chronic organ failure, genetic factors (male gender and non-White ethnic origin in North America), and the presence of bacteremia.[5,7-10] Pulmonary infections cause approximately half of all sepsis cases within the United States, followed by intra-abdominal and genitourinary infections.[2] In approximately one-third of sepsis cases, a pathogen is not identified making deescalation from broad spectrum to a more narrowed antimicrobial regimen difficult.[2] A recent study demonstrated that diarrheal illness is the most common etiology of sepsis globally, with patterns of sepsis incidence varying significantly by geographical location, highlighting the need for knowledge of local patterns to determine the overall risk by an organism.[11]

KEY CONCEPT Gram-positive and Gram-negative bacteria, fungal species, and viruses may cause sepsis (Table 84–3). Gram-positive infections account for 30% to 50% of sepsis and septic shock cases.[5,7,8] The percentages of Gram-negative, polymicrobial, and viral sepsis cases are 25%, 25%, and 4%, respectively.[5,7,8,12] A multinational study of 14,000 critically ill patients showed an increase in Gram-negative bacterial causes of infection compared to Gram-positive bacterial and fungal causes.[2] Multidrug-resistant (MDR) bacteria are responsible for approximately 25% of sepsis cases, are difficult to treat due to fewer antimicrobial options, and increase mortality.[7,8] The rate of fungal infections has significantly increased with *Candida albicans* as the most common fungal species identified; however, nonalbicans species (*Candida glabrata, Candida krusei,* and *Candida tropicalis*) have increased from 24% to 46%.[5,13,14] Other fungi identified as causes of sepsis include species of *Cryptococcus, Coccidioides, Fusarium*, and *Aspergillus*.

PATHOPHYSIOLOGY

The development of sepsis is complex and multifactorial. The normal host response to infection is designed to localize and control microbial invasion and initiate repair of injured tissue through phagocytic cells and inflammatory mediators.[4] KEY CONCEPT Sepsis results when the interplay between the host's immune, inflammatory, and coagulant responses becomes exaggerated, extending to normal tissue distant from the initial tissue site.

Table 84–1

The SOFA Score

SOFA Score	1	2	3	4
Respiration PaO$_2$/FiO$_2$, mm Hg	< 400	< 300	< 200 ___with respiratory support___	< 100
Coagulation Platelets × 10^3/mm^3	< 150	< 100	< 50	< 20
Liver Bilirubin, mg/dL (µmol/L)	1.2–1.9 (20–32)	2.0–5.9 (33–101)	6.0–11.9 (102–204)	≥ 12.0 (> 204)
Cardiovascular Hypotension	MAP[a] < 70 mm Hg	Dopamine ≤ 5 or dobutamine (any dose)[b]	Dopamine > 5–15, epinephrine ≤ 0.1, or norepinephrine ≤ 0.1	Dopamine > 15, epinephrine > 0.1, or norepinephrine > 0.1
Central nervous system Glasgow Coma Score	13–14	10–12	6–9	< 6
Renal Creatinine, mg/dL (µmol/L) or urine output	1.2–1.9 (110–170)	2.0–3.4 (171–299)	3.5–4.9 (300–400) or < 500 mL/day	≥ 5.0 (> 440) or < 200 mL/day

[a] MAP (mean arterial pressure) = 1/3 (SBP – DBP) + DBP.

[b] Adrenergic agents administered for at least 1 hour (doses given are in mcg/kg/min).

Pro- and Anti-inflammatory Mediators

The key factor in the development of sepsis is inflammation, which is intended to be a local and contained response to infection or injury. Infection or injury is controlled through proinflammatory and anti-inflammatory mediators. Proinflammatory mediators facilitate clearance of the injuring stimulus, promote resolution of injury, and are involved in processing of damaged tissue.[4,14-17] To control the intensity and duration of the inflammatory response, anti-inflammatory mediators are released that act to regulate proinflammatory mediators.[16,17] The balance between pro- and anti-inflammatory mediators localizes infection/injury of host tissue.[14-17] However, systemic responses ensue when equilibrium in the inflammatory process is lost.

The inflammatory process in sepsis is linked to the coagulation system. Proinflammatory mediators may have procoagulant and antifibrinolytic effects, whereas anti-inflammatory mediators may have fibrinolytic effects. A key factor in the inflammation of sepsis is activated protein C that enhances fibrinolysis and inhibits inflammation. Protein C levels are decreased in many septic patients.

The initial immune response to a severe infectious syndrome like sepsis is associated with increased neutrophil production and the release of both immature (eg, bands) and mature forms of neutrophils into the bloodstream. This increased immature neutrophil presence is associated with more severe disease and is more likely to result in the formation of neutrophil extracellular traps leading to decreased functional capacity. Ultimately, this increased number of band neutrophils over time can lead to endothelial tissue damage and hypercoagulation.[18]

Table 84–2

Quick SOFA (qSOFA) Criteria

- Respiratory rate ≥ 22 breaths/min
- Altered mentation
- Systolic blood pressure ≤ 100 mm Hg
- Positive qSOFA score indicated by meeting ≥ 2 criteria

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of sepsis varies, and the rate of development of clinical manifestations may differ from patient to patient.

A physical examination should be performed rapidly and efficiently when sepsis is suspected, with efforts directed toward uncovering the most likely cause of sepsis. The patient may not provide any medical history; therefore, historical data may be obtained from medical records and/or family. The patient's medical condition, recent illnesses, infections, or activities may provide valuable information about the cause of sepsis.

Table 84–3

Pathogens in Sepsis

Organism	Frequency (%)
Gram-positive bacteria	50–55
Gram-negative bacteria	35–40
Fungi	5
Polymicrobial	5
Anaerobes (alone)	1
Parasites	Variable
Viruses	Variable

Data from Martin GS, Mannino DM, Eaton S, Moss M. The epidemiology of sepsis in the United States from 1979 through 2000. N Engl J Med. 2003;348(16):1546–1554.

Possible Physical Examination Results in Sepsis

HEENT: Scleral icterus, dry mucous membranes, pinpoint pupils, dilated and fixed pupils, nystagmus

Neck: Jugular venous distention, carotid bruits

Lungs: Crackles (rales), consolidation, egophony, absent breath sounds

CV: Irregular rhythm, S_3 gallop, murmurs

Abd: Tense, distended, tender, rebound, guarding, hepatosplenomegaly

Rectal: Decreased tone

Exts: Swollen calf, disparity of blood pressure between upper extremities

Neurologic: Agitation, confusion, delirium, obtundation, coma

Skin: Cold, clammy, or warm; hyperemic skin; rashes

Diagnostic and Laboratory Tests

Microbiologic cultures should be obtained before antimicrobial therapy is initiated as long as this does not significantly delay the start of therapy. However, cultures take 6 to 72 hours for results to be completed and often are negative (no growth of bacterial organisms). Negative cultures do not rule out the presence of infection. Administering antimicrobials before obtaining cultures may lead to a false-negative culture. Rapid diagnostics of blood cultures allows for identification of specific pathogens within as little as 20 minutes to 3 hours after initial growth is identified. However, not all healthcare systems have this technology available. Additionally, if these technologies are used, they must be in conjunction with antimicrobial stewardship personnel to be cost-effective.[19]

At least two sets of blood cultures should be obtained to rule out contamination, with at least one set drawn percutaneously and one set drawn through each vascular access device present for greater than 48 hours.

Cultures of urine (with urinalysis), respiratory secretions, cerebrospinal fluid, and wounds should be obtained if the clinical presentation suggests infection of these specific fluids, tissues, or organs. Laboratory tests should be performed to evaluate infection or complications of sepsis, including complete blood count (CBC) with differential, coagulation parameters, comprehensive metabolic panel (CMP), serum lactate concentration, arterial blood gas (ABG), and appropriate diagnostic radiographic imaging studies.

The use of biomarkers of sepsis, such as endotoxin and procalcitonin, has been controversial. Measurement of endotoxin, procalcitonin, or other markers in blood or serum is not routinely recommended. Concentrations of procalcitonin in serum are usually increased in sepsis but fail to differentiate between infection and inflammation. However, procalcitonin has a high negative predictive value and may allow for the discontinuation of antibiotics. It is important to note that the measurement of any biomarker, including procalcitonin, should be used in conjunction with the patient's overall clinical assessment and never be used as the sole indicator for altering microbial therapy.

Complications of Sepsis

KEY CONCEPT Recognition and treatment of sepsis complications, particularly organ failure, is essential to improve outcomes. The cumulative burden of sepsis complications is the leading factor of mortality. The risk of death increases 20% with the failure of each

Clinical Presentation and Diagnosis of Sepsis

The signs and symptoms of septic patients are referred to as early and late sepsis.

Signs and Symptoms

The initial clinical signs and symptoms represent early sepsis, and they include fever, chills, and change in mental status. Other signs and symptoms include the following:

- **Tachycardia**
- **Tachypnea**
- Nausea and vomiting
- Hyperglycemia
- Myalgias
- Lethargy and malaise
- **Proteinuria**
- Leukocytosis
- Hypoxia
- Hyperbilirubinemia

Septic patients may have an elevated, low, or normal temperature. The absence of fever is common in neonates and elderly patients. Hypothermia is associated with a poor prognosis. Hyperventilation may occur before fever and chills and may lead to respiratory alkalosis. Disorientation and confusion may develop early in septic patients, particularly in the elderly and patients with preexisting neurologic impairment. Disorientation and confusion may be related to the infection or due to sepsis signs and symptoms (eg, hypoxia).

Late sepsis represents a slow process that develops over several hours of hypoperfusion. Signs and symptoms of late sepsis include the following:

- Lactic acidosis
- **Oliguria**
- **Leukopenia**
- Thrombocytopenia
- Myocardial depression
- Pulmonary edema
- Hypotension
- Hypoglycemia
- Gastrointestinal hemorrhage

Oliguria often follows hypotension because of decreased renal perfusion. Metabolic acidosis ensues because of diminished clearance of lactate by the kidneys and liver.

Patient Encounter Part 1

A 58-year-old man with a history of hypertension, obesity, and COPD presents to the emergency department with complaints of fever, cough, and increased sputum production for the last 2 days. The patient is becoming increasingly short of breath and confused.

What information is suggestive of infection and/or sepsis?

What information do we need in order to confirm or diagnose sepsis in this patient?

additional organ. The most common complications are respiratory and cardiovascular compromise, usually seen as acute respiratory distress syndrome (ARDS), hemodynamic compromise, and elevated serum lactate levels. Other complications include altered mentation, acute kidney injury (AKI) that may require renal replacement therapy, paralytic ileus, disseminated intravascular coagulation (DIC), and adrenal insufficiency.[2]

TREATMENT AND OUTCOME EVALUATION

Desired Outcomes

KEY CONCEPT The primary treatment goal of sepsis is to prevent morbidity and mortality through rapid recognition and intervention. Treatment is aimed at early implementation of therapies, such as fluid resuscitation and antimicrobials, reducing or eliminating organ dysfunction, eliminating the source of infection, avoiding adverse reactions of treatment, and providing cost-effective therapy.[20-26]

General Approach to Treatment

Once a diagnosis of sepsis has been made, rapid intervention with appropriate therapies is crucial to decrease morbidity and mortality.[20,22]

In addition to appropriately timed diagnostic tests, pertinent approaches in the management of septic patients are as follows (Figure 84–1)[26]:

1. Prompt recognition of the septic patient and early implementation of therapies.
2. Fluid therapy, using crystalloids primarily, to restore intravascular volume depletion.
3. Early administration of broad-spectrum antimicrobial therapy.
4. Vasopressor therapy, using norepinephrine initially, to maintain hemodynamic stability (on average an MAP of 65 mm Hg [8.6 kPa]) in patients with septic shock refractory to fluid resuscitation.
5. Intravenous (IV) hydrocortisone may be considered for patients who remain hemodynamically unstable despite adequate fluid resuscitation and vasopressor support.
6. Glycemic control via infusion of regular insulin to maintain glucose levels between 140 and 180 mg/dL (7.8 and 10.0 mmol/L).
7. Adjunctive therapies: blood product administration, analgesia, sedation, neuromuscular blockade, renal replacement therapy, sodium bicarbonate therapy, venous thromboembolism (VTE) prophylaxis, stress ulcer prophylaxis, and nutrition.

Treatment for sepsis focuses on infection, inflammation, hypoperfusion, and widespread tissue injury. Septic patients may require multiple simultaneous treatment regimens to achieve desired outcomes of decreased morbidity and mortality.

Initial Resuscitation

A landmark study of early goal–directed therapy (EGDT) using a standardized protocol that required the use of a special catheter for central venous oxygen saturation monitoring decreased 28-day mortality in septic patients by approximately 16%.[25] Three subsequent randomized controlled studies comparing EGDT to groups of patients receiving contemporary care (with or without the use of protocols) found no differences in mortality.[27] These results demonstrate that continued focus on early recognition and treatment of these patients may play a more important role than protocol-based therapy; however, the use of EGDT was not associated with harm.

Upon recognition of sepsis, resuscitation should begin immediately. Within the first 3 hours, at least 30 mL/kg of crystalloid fluid should be administered intravenously. Subsequent fluid administration should be guided by frequent reassessment of hemodynamic status and dynamic variables to predict fluid responsiveness and prevent volume overload. The use of static variables, such as central venous pressure (CVP), to assess the need for additional fluid administration should not be used alone. Rather, these variables in conjunction with dynamic measures, such as the passive leg raise technique, fluid challenges, and stroke volume or pulse pressure variation, may be better predictors of fluid responsiveness.[22,25,26,28]

Emerging noninvasive techniques, such as the use of cardiac ultrasound, have recently shown reliability in assessing intravascular volume status through measuring inferior vena cava diameter changes and collapsibility.[29,30] Resuscitation should also target the normalization of blood lactate levels in patients with an initially elevated blood lactate as a marker of improved tissue perfusion.[22]

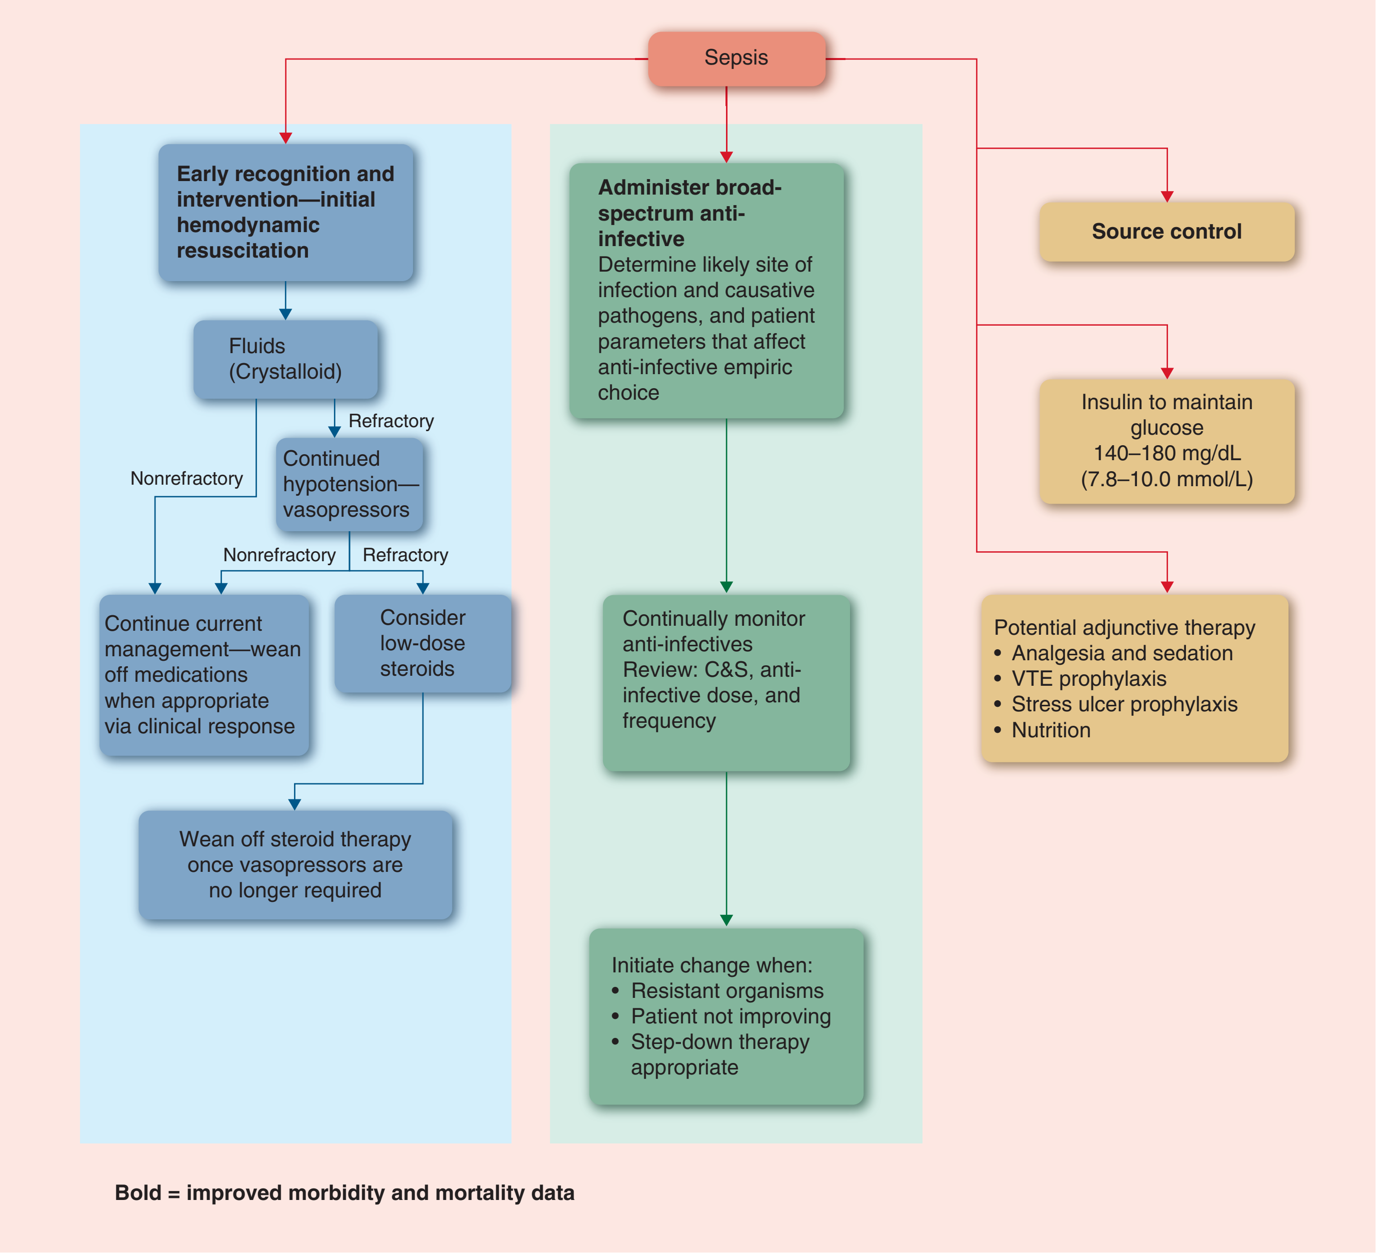
Fluid Therapy

Crystalloid fluids (such as 0.9% sodium chloride or lactated Ringer solutions) or colloids (albumin products) are used for resuscitation, and clinical studies comparing these two fluids types have found them to be equivalent.[28,31,32] Crystalloids require more fluid volume, which may lead to more edema (utilize caution in patients at risk of fluid overload, eg, congestive heart failure, renal failure, and ARDS); however, albumin is significantly more expensive. Hydroxyethyl starch (HES), another type of colloid, should not be used due to studies demonstrating increased morbidity and mortality.[33,34] For these reasons, crystalloids are preferred versus colloids for initial resuscitation, except in cases where large amounts of crystalloids are needed, and hypervolemia may be harmful to the patient.[22]

After initial fluid administration, there remains clinical controversy surrounding the appropriate type of fluid for continued resuscitation. There are data that suggest potential benefit of using balanced crystalloid solutions or a chloride-restrictive strategy. Large (n > 29,000), prospective, multiple-crossover trials suggest the administration of large volumes of isotonic saline may be associated with increased incidences of AKI and renal replacement therapy secondary to hyperchloremic metabolic acidosis.[35,36]

Anti-infective Therapy

KEY CONCEPT Appropriate empiric antimicrobial therapy decreases 28-day mortality compared with inappropriate



Sepsis
Early recognition and intervention—initial hemodynamic resuscitation
Fluids (Crystalloid)
Refractory
Nonrefractory
Continued hypotension—vasopressors
Nonrefractory
Refractory
Continue current management—wean off medications when appropriate via clinical response
Consider low-dose steroids
Wean off steroid therapy once vasopressors are no longer required
Administer broad-spectrum anti-infective
Determine likely site of infection and causative pathogens, and patient parameters that affect anti-infective empiric choice
Continually monitor anti-infectives
Review: C&S, anti-infective dose, and frequency
Initiate change when:
• Resistant organisms
• Patient not improving
• Step-down therapy appropriate
Source control
Insulin to maintain glucose 140–180 mg/dL (7.8–10.0 mmol/L)
Potential adjunctive therapy
• Analgesia and sedation
• VTE prophylaxis
• Stress ulcer prophylaxis
• Nutrition
Bold = improved morbidity and mortality data

FIGURE 84–1. Therapeutic approach to sepsis. (C&S, cultures and susceptibilities.)

empiric therapy (24% vs 39%).[20,21,37] Additionally, appropriate therapy administered within 1 hour of sepsis recognition also decreases complications and mortality.[20,21,37] Empiric antimicrobial therapy should include multiple agents for most cases, depending on the likely site of infection and causative pathogens. Anti-infective clinical trials in sepsis and septic shock patients are scarce and have not demonstrated differences among agents; therefore, factors that determine selection are as follows:

- Site/source of infection.
- Causative pathogens.
- Community- or nosocomial-acquired infection.
- Immune status of patient.
- Antibiotic susceptibility and resistance profile for the institution and local community. Clinicians should be cognizant of growing prevalence of bacterial resistance in community and healthcare settings.
- Patient history (underlying disease, previous cultures or infections, including any recent antibiotic therapy, and drug allergy/intolerance).
- Adverse reactions.
- Cost.

Anti-infective regimens should be broad spectrum since delays in the appropriate therapy result in increased mortality. In the subset of patients with septic shock, empiric therapy should include combination regimens with multiple antibiotics from different mechanistic classes (eg, two antipseudomonal antimicrobials in patients with known risk factors to ensure appropriate coverage of MDR organisms). Please reference Chapter 69 for more antimicrobial information and other chapters based on specific disease state leading to sepsis.

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Hypertension, obesity, COPD

FH: Father has a history of hypertension, hyperlipidemia, and chronic kidney disease; mother had a history of hypertension, diabetes mellitus, hyperlipidemia, coronary artery disease, died from myocardial infarction at age 68

SH: High school teacher; previous smoker (one pack per day, quit 1 year ago); rare alcohol intake

Allergies: NKDA

Meds: Lisinopril 20 mg by mouth once daily; hydrochlorothiazide 25 mg by mouth once daily; tiotropium respimat two inhalations once daily; albuterol inhaler two puffs every 6 hours as needed; multivitamin one tablet by mouth once daily, aspirin 81 mg by mouth once daily

ROS: Unable to obtain; patient has become more confused

PE:

Within normal limits except as noted below

VS: BP 86/48 mm Hg, P 132 beats/min, RR 34 breaths/min, T 39.2°C (102.6°F)

Neurologic: Obtunded, oriented to person only

Skin: Cool, clammy

Labs: Serum creatinine 2.2 mg/dL (194.5 μmol/L); glucose 201 mg/dL (11.2 mmol/L); white blood cells: leukocytosis (18,300/mm^3 [18.3×10^9/L]) with left shift; lactic acid 4.2 mEq/L (4.2 mmol/L)

Cultures: Blood and sputum cultures pending

Radiology: Chest X-ray consistent with left lower lobe infiltrate

According to the patient's parameters, what is his most likely diagnosis (ie, systemic inflammatory response syndrome, sepsis, or septic shock)?

What are the goals of treatment?

Formulate an initial plan for therapy.

Monitoring and Treatment Strategies to Maximize Efficacy and Minimize Toxicity for Antimicrobials

- Administer broad-spectrum antimicrobials for initial therapy as early as possible and within the first hour of recognition of sepsis.
- Appropriate cultures should be obtained before initiating antibiotic therapy but should not prevent prompt administration.
- Administer antibiotics that concentrate at the site of infection.
- Evaluate and integrate rapid diagnostic findings if available to ensure optimal therapy.
- Monitor patient parameters to ensure adequate dosing.
- Abnormal renal and hepatic function will increase drug concentration and predispose the patient to toxicity.
- Ensure antibiotic dosing is changed to normal doses once renal dysfunction has resolved to limit the development of treatment failure, antimicrobial resistance, or both.
- Septic patients may have increased volume of distribution due to initial large-volume resuscitation.
- Reevaluate the initial dosing regimen daily to optimize activity, prevent the development of resistance, reduce toxicity, and decrease costs.
- Initiate step-down therapy based on microbiologic cultures to prevent resistance, reduce toxicity, including *Clostridioides difficile* infection, and minimize cost.
- Monotherapy is equivalent to combination therapy once a causative pathogen has been identified in the vast majority of cases.

Patient Encounter Part 3: Treatment and Outcome Evaluation

The patient has been intubated for acute hypoxic respiratory failure secondary to pneumonia. He remains hypotensive despite previous interventions. His serum creatinine remains elevated at 3.1 mg/dL (274.1 μmol/L), and he has no urinary output.

What additional therapies will you consider adding to this patient?

Duration of Anti-infective Therapy

Average duration of antimicrobial therapy for septic patients is 7 to 10 days. However, durations vary depending on the site of infection and response to therapy. Step-down therapy from IV to oral antimicrobials is recommended in certain targeted patients who are hemodynamically stable, afebrile for 48 to 72 hours, have a normalized WBC, have an organism susceptible to oral therapies, and are able to take oral medications. Antimicrobials should be discontinued if it is determined the cause of shock was not infectious.

Source Control

Evaluate septic patients for the presence of a localized infection amenable to source control measures. Common source control measures include drainage and debridement, device removal, and amputation.[22,23] Implementation of source control methods should be instituted as soon as possible following initial fluid resuscitation. The selection of optimal source control methods must weigh benefits and risks of the intervention. Source control measures may cause complications (bleeding, fistulas, and organ injury); therefore, the method with the least risk should be employed.[22]

HEMODYNAMIC SUPPORT

Vasopressors and Inotropic Therapy

KEY CONCEPT When fluid resuscitation does not provide adequate arterial pressure and organ perfusion, vasopressors and/or inotropic agents should be initiated. Vasopressors are recommended in patients with a systolic blood pressure less than 90 mm Hg or MAP lower than 60 to 65 mm Hg (8.0–8.6 kPa), after failed treatment with crystalloids.[22,25,26] Vasopressors and inotropes are effective in treating life-threatening hypotension and improving cardiac index, but complications such as tachycardia and myocardial ischemia require slow titration of the adrenergic agents to restore MAP without impairing stroke volume. Vasopressor therapy may also be required transiently to sustain life and maintain perfusion in the face of life-threatening hypotension, even when fluid resuscitation is in progress and hypovolemia has not yet been corrected. Agents commonly considered for vasopressor or inotropic support include norepinephrine, epinephrine, dopamine, phenylephrine, vasopressin, and dobutamine. Norepinephrine is the first-line vasopressor to correct hypotension in septic shock.[22]

Norepinephrine is a potent α-adrenergic agent with less pronounced β-adrenergic activity. Doses of 0.01 to 3 mcg/kg/min can reliably increase blood pressure through vasoconstriction with small changes in heart rate or cardiac index. Norepinephrine is a more potent agent than dopamine in refractory septic shock.[22,25,26] Norepinephrine induces less arrhythmias compared with dopamine.[38]

Dopamine is an α- and β-adrenergic agent with dopaminergic activity. Low doses of dopamine (1–5 mcg/kg/min) maintain renal perfusion; higher doses (> 5 mcg/kg/min) exhibit α- and β-adrenergic activity and are frequently utilized to support blood pressure and improve cardiac function, mainly through increasing stroke volume and heart rate. Because of the effects on heart rate, dopamine causes more tachycardia and thus increases potential for arrhythmias versus norepinephrine. Based on these data, dopamine should not be used routinely in the management of septic shock.[22,38] Low doses of dopamine should not be used for renal protection as part of the treatment of sepsis.[22,25,26]

Epinephrine is a nonspecific α- and β-adrenergic agonist that can increase cardiac index and produce significant peripheral vasoconstriction. Some human and animal studies suggest it can also increase lactate levels and impair blood flow to the splanchnic system; however, studies comparing norepinephrine to epinephrine show no difference in mortality rates. Epinephrine may be added to norepinephrine in patients with persistent hypotension.[22,25,26]

Phenylephrine is a fast-acting, short-acting pure α_1-agonist. Phenylephrine is the least likely vasopressor to cause tachycardia but may decrease stroke volume. Phenylephrine should be reserved for use in patients with high cardiac output in whom tachycardia or ischemia limits the use of other vasopressors or as salvage therapy.[22,25,26]

Vasopressin levels are increased during hypotension to maintain blood pressure by vasoconstriction. However, there is a vasopressin deficiency in septic shock. Low, fixed doses of exogenous vasopressin increase MAP, leading to the discontinuation of catecholamines. However, routine use of vasopressin with norepinephrine is not recommended because of no difference in mortality compared with norepinephrine monotherapy.[39] Vasopressin is a direct vasoconstrictor without inotropic or chronotropic effects and may result in decreased cardiac output and hepatosplanchnic flow. The addition of vasopressin to norepinephrine may be considered in patients with refractory shock despite adequate fluid resuscitation and high-dose catecholamines.[22,25,26]

Dobutamine is recommended as the first-line inotropic agent. Dobutamine is a β-adrenergic inotropic agent that can be utilized for the improvement of cardiac output and oxygen delivery. Doses of 2 to 20 mcg/kg/min increase cardiac index; however, heart rate increases significantly. Dobutamine should be considered in septic patients with adequate filling pressure and blood pressure, but low cardiac index. If used in hypotensive patients, dobutamine should be combined with vasopressor therapy.[22,25,26]

Patient Encounter Part 4

Three days later, the patient's blood pressure begins to respond to therapy with an MAP remaining greater than 65 mm Hg (8.6 kPa) on minimal vasopressor support.

What changes to the patient's medication regimen do you recommend?

Angiotensin II is the newest drug approved for the treatment of hypotension in adults with septic or other distributive shock states. A naturally occurring hormone of the renin–angiotensin–aldosterone system, angiotensin causes vasoconstriction and increases the release of aldosterone, which increases blood pressure. A recent study evaluated the use of angiotensin II in patients with vasodilatory shock states, like septic shock, who were requiring high-dose vasopressors and found that administration of angiotensin II was associated with a significant increase in the number of patients who reached goal MAP at 3 hours and allowed for decreased catecholamine doses of other vasopressors.[40] The exact place in therapy for angiotensin II has not been established, but multimodal utilization of different vasoactive medications may allow for decreased individual vasopressor doses, potentially decreasing side effects.

Corticosteroids

Stress-induced adrenal insufficiency complicates 9% to 24% of septic patients and is associated with increased mortality. The role of steroid use in septic shock remains unclear. Previous studies have demonstrated a mortality benefit or quicker reversal of shock in patients with sepsis-induced adrenal insufficiency treated with hydrocortisone.[41] However, a large, multicenter, randomized controlled trial (CORTICUS) showed no difference in mortality rates in septic shock patients treated with hydrocortisone.[42] KEY CONCEPT For these reasons, the use of IV hydrocortisone at a dose of 200 mg/day should be reserved for patients who remain hemodynamically unstable despite fluid and vasopressor therapy.[22] Patients should be tapered from steroid therapy when vasopressors are no longer required. The decision of whether to taper and how to taper hydrocortisone doses is dependent on individual patient characteristics or provider preference. There is no standard recommendation; however, an example of a steroid tapering regimen may be seen in the CORTICUS trial.[42]

Glucose Control

The optimal blood glucose range in septic patients is unknown. Tight glycemic control (80–110 mg/dL [4.4–6.1 mmol/L]) improved survival in postoperative surgical patients but did not show a benefit in medical critically ill patients.[43,44] Subsequent studies, such as the large NICE-SUGAR trial, do not demonstrate a mortality benefit in favor of tight glycemic control, but actually a higher incidence of severe hypoglycemia and increased mortality rates.[45] KEY CONCEPT Following initial stabilization of septic patients, current guidelines recommend initiating IV insulin therapy when two consecutive blood glucose measurements are greater than 180 mg/dL (10.0 mmol/L) and then maintaining a blood glucose of less than or equal to 180 mg/dL (10.0 mmol/L). Blood glucose levels should be monitored frequently, every 1 to 2 hours, until glucose values and insulin infusion rates are stable, every 4 hours thereafter.[22]

Adjunctive Therapies

▶ *Blood Product Administration*

There are no trials showing the optimal hemoglobin concentration in patients with sepsis. However, based on other studies that included subgroups of septic patients, with the exception of myocardial ischemia, severe hypoxemia, acute hemorrhage, or ischemic coronary artery disease, it is recommended to target a hemoglobin concentration of 7 to 9 g/dL (70–90 g/L; 4.34–5.59 mmol/L), and red blood cell transfusion should occur when the hemoglobin concentration is less than 7 g/dL (70 g/L; 4.34 mmol/L).[22,46] Erythropoietin-stimulating agents, fresh frozen plasma, and antithrombin should not be administered, unless other compelling indications exist, to treat sepsis-induced abnormalities.[22]

▶ *Sedation, Analgesia, and Neuromuscular Blockade*

It is common for sepsis patients to require mechanical ventilation during their course of therapy. These patients may require analgesic or sedative agents to facilitate mechanical ventilation. Historically, concerns for patient safety and posttraumatic stress disorder emphasized the need for sedation in these patients. However, there continues to be ample data indicating that, while sedation may be necessary, limiting exposure to certain sedative medications, specifically benzodiazepines, may improve morbidity and mortality rates. When sedation is needed, a standardized protocol targeting specific endpoints should be utilized.[22,47]

Neuromuscular blockade usually is reserved for patients in whom sedation alone does not improve the effectiveness of mechanical ventilation. Neuromuscular blockers may lead to prolonged skeletal muscle weakness and should be avoided if possible, especially if receiving concomitant corticosteroid therapy, which can increase the risk of critical illness polyneuropathy. Patients requiring neuromuscular blockade should be monitored, and intermittent bolus doses or continuous infusion should be utilized. Monitor depth of neuromuscular blockade with either train-of-four stimulation or other forms of clinical assessment when using continuous infusion. Patients with early, sepsis-induced ARDS with a partial pressure of oxygen (PaO_2)/fraction of inspired oxygen (FiO_2) less than 150 mm Hg (20.0 kPa) may benefit from a short course of a neuromuscular blocking agent not to exceed 48 hours.[22]

▶ *Renal Replacement Therapy*

Patients who develop AKI as a manifestation of sepsis may require some type of renal replacement therapy. There are no data currently that suggest superiority for either continuous or intermittent modalities of hemodialysis as both have demonstrated similar mortality rates. In patients who are hemodynamically unstable, continuous renal replacement therapy may be more beneficial due to less overall hypotension during therapy.

▶ *Sodium Bicarbonate Therapy*

It has been theorized that vasopressors that act on catecholamines to increase blood pressure (eg, norepinephrine, epinephrine, phenylephrine, dopamine) may become less responsive at pH values less than 7.15. However, there are no robust data that have demonstrated improved hemodynamics, decreased vasopressor requirements, or improved clinical outcomes when sodium bicarbonate is administered at lower pH values. Conversely, bicarbonate administration has been associated with sodium and fluid overload although direct causality has not been established. For these reasons, sodium bicarbonate therapy should only be considered in patients with pH less than 7.15 who are not responsive to vasopressors or have increasing vasopressor requirements to maintain an MAP of at least 65 mm Hg.[22]

▶ *Metabolic Resuscitation*

There has been growing interest in vitamin deficiencies in patients with sepsis, specifically vitamin C and thiamine (vitamin B1). Several studies have evaluated the administration of high-dose vitamin C, thiamine, or the combination of vitamin C, thiamine, and hydrocortisone (commonly referred to as metabolic resuscitation) on vasopressor requirements and patient outcomes.[48,49] There are no robust data to support the use of these medications in patients with septic shock. Ongoing studies will help elucidate if there is clinical value in the future use of these interventions.

▶ *Venous Thromboembolism Prophylaxis*

Combination of pharmacologic and mechanical prophylaxis against VTE is recommended for septic patients when possible. Low-dose unfractionated heparin, low-molecular-weight heparin (eg, enoxaparin or dalteparin), or pentasaccharide therapy (eg, fondaparinux) may be utilized. Graduated compression stocking or an intermittent compression device is recommended for patients with a contraindication to heparin products (thrombocytopenia, severe coagulopathy, active bleeding, or recent intracerebral hemorrhage).[22]

▶ *Stress Ulcer Prophylaxis*

Patients with severe sepsis are at increased risk of developing a stress ulcer bleeding event. Stress ulcer prophylaxis using either a histamine-receptor antagonist (H2 blocker) or proton pump inhibitor (PPI) is recommended in septic patients. Patients at the greatest risk of stress ulcers include those who are coagulopathic, mechanically ventilated (> 48 hours), or hypotensive. Histamine 2–receptor antagonists (eg, ranitidine) are more efficacious than sucralfate. There is an ongoing debate to determine if PPIs (eg, omeprazole) are more efficacious than H2 blockers with low-quality data showing conflicting outcomes.[22,50] Both, however, demonstrate equivalence in the ability to increase gastric pH.[22] The benefit of prophylaxis must be weighed against the potential effect of increased stomach pH and development of infectious complications, such as hospital-acquired pneumonia and/or *C. difficile* infection. When patients no longer have an indication for stress ulcer prophylaxis or at major transitions of care (eg, transition out of the ICU), it is imperative that the stress ulcer prophylactic medication is discontinued to avoid patients being discharged home on unnecessary medications.

▶ *Nutrition*

Meeting the nutritional needs of septic patients can be challenging, especially in patients who are hemodynamically unstable. When possible, early initiation of enteral nutrition should be considered to maintain gut mucosa and potentially decrease the risk of bacterial translocation leading to infection. Patients who are hemodynamically unstable may not tolerate enteral nutrition and are at risk of gut ischemia. Parenteral nutrition alone or in conjunction with enteral nutrition should not be initiated in the first 7 days as this has not been shown to improve outcomes.[22]

Prognosis

There are various factors that influence an outcome. Gram-negative bacteria are more likely to produce septic shock than Gram-positive bacteria (50% vs 25%) and have a higher mortality rate than other pathogens. This may be related to the severity of the underlying condition. Patients with rapidly fatal conditions, such as leukemia, aplastic anemia, and burns, have a worse prognosis than patients with nonfatal underlying conditions, such as diabetes mellitus or chronic renal insufficiency. Other factors that worsen the prognosis of septic patients include advanced age, malnutrition, resistant bacteria, utilization of medical devices, and immunosuppression. Data for long-term mortality are lacking (it is estimated that the mortality for sepsis survivors within the first year is 20%).[51] Patients may have prolonged physical disability related to muscle weakness and posttraumatic stress.

SEPSIS AND SEPTIC SHOCK: CORONAVIRUS DISEASE 2019 (COVID-19)

While most patients infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) will experience mild–moderate COVID-19 infection, a significant percentage (~5%) will require intensive care unit management due to mechanical ventilation and/or septic shock. In these patients, viral replication rapidly increases, highlighting the profound inflammatory response (ie, cytokine storm) leading to diffuse alveolar wall thickening and macrophage distribution into airspaces with subsequent pulmonary edema and formation of ground-glass infiltrates. These pathophysiologic features can lead ultimately to ARDS and profound respiratory failure.[52] In addition, SARS-CoV-2 infection is associated with significant arterial and venous complications, occurring in as much as 35% of hospitalized critically ill patients. Prothrombotic divergence is characterized by decreased concentrations of protein C, protein S, and antithrombin coupled with elevated D-dimer, fibrinogen, and factor VIII concentrations. This coagulation imbalance leads to microthrombi findings upon autopsy in multiple organ systems.[53] These findings are primarily responsible for the significant morbidity and mortality in COVID-19 patients complicated by sepsis syndromes.

Treatment is divided primarily into nonpharmacologic and pharmacologic therapies for severe COVID-19. Nonpharmacologic therapy is similar to ARDS with a specific emphasis on proning, which is recommended for patients with persistent hypoxemia despite increasing supplemental oxygen requirements who otherwise are not indicated for intubation. Pharmacologic treatment for septic shock is similar to other etiologies (including VTE prophylaxis/anticoagulation when indicated). A number of treatments aimed at critically ill patients with severe COVID-19 have been attempted, including convalescent plasma, remdesivir, and dexamethasone. While data are mixed with regard to clinical outcomes of convalescent plasma and remdesivir, dexamethasone is currently recommended for all hospitalized patients requiring supplemental oxygen, with the greatest benefit of decreased mortality demonstrated in those patients receiving mechanical ventilation.[54]

Patient Care Process

Collect Information:

- Retrieve available diagnostic and laboratory data, especially CBC with differential, CMP, ABG, and lactic acid.
- Measure vital signs, including temperature, heart rate, respiratory rate, and blood pressure.
- Speak with patient/family and review records to identify previous antimicrobial history, microbiologic cultures, and medication allergies.

Assess the Information:

- Based on physical examination and review of systems, determine whether the patient meets criteria for sepsis.
- Assess for a potential source of infection.
- Identify comorbidities, concomitant medications, and/or laboratory findings that may impact antimicrobial choices.
- Understand which parameters indicate effective/ineffective resuscitation. Plan for additional resuscitation therapy if the patient remains hypotensive.

Develop a Care Plan:

- Formulate an appropriate plan for antimicrobial therapy, which should include starting broad-spectrum agents that cover the most likely pathogens within 1 hour of suspecting sepsis.
- Make recommendations to control the source of infection.
- Develop a strategy to optimize hemodynamics. Crystalloid fluids should be used first, followed by vasopressors and/or inotropes. Corticosteroids may be utilized in patients who remain hemodynamically unstable.
- Formulate appropriate dosing regimens for medications involved in therapy and revise as needed.
- Consider the need for adjunctive therapies such as analgesics, sedatives, insulin, neuromuscular blockers, blood product administration, renal replacement therapy, sodium bicarbonate, venous thromboembolism prophylaxis, stress ulcer prophylaxis, and nutrition.

Implement the Care Plan:

- Patient parameters may change frequently, thus requiring modifications of therapy. Reassess vital signs and laboratory values often and adjust medications and dosing regimens as needed.
- Involve the patient and family members in each step of the care plan.

Follow-up: Monitor and Evaluate:

- Continually monitor patient parameters to ensure optimal therapy to minimize morbidity and mortality.
- Continue antimicrobial therapy on average for a total of 7 to 10 days, depending on the site of infection and response to therapy. Monitor for ongoing signs and symptoms of infection, including leukocytosis, fever, hypotension, and tachycardia.
- Step-down therapy from IV to oral antimicrobials when the patient is hemodynamically stable, afebrile, has a normalized WBC, has a pathogen susceptible to oral therapy, and is able to take oral medications.
- Escalate or deescalate antimicrobial therapy based on culture and susceptibility results, which should be assessed daily.

Abbreviations Introduced in This Chapter

ABG	Arterial blood gas
AKI	Acute kidney injury
ARDS	Acute respiratory distress syndrome
CBC	Complete blood count
CMP	Comprehensive metabolic panel
CVP	Central venous pressure
DIC	Disseminated intravascular coagulation
EGDT	Early goal–directed therapy
Fio$_2$	Fraction of inspired oxygen
HES	Hydroxyethyl starch
IV	Intravenous
MAP	Mean arterial pressure
MDR	Multidrug-resistant
Pao$_2$	Partial pressure of oxygen
PPI	Proton pump inhibitor
SOFA	Sequential (Sepsis-related) Organ Failure Assessment
VTE	Venous thromboembolism

Superficial Fungal Infections

Kathryn A. Fuller and Lauren S. Schlesselman

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the underlying pathophysiology of vulvovaginal candidiasis (VVC), oropharyngeal candidiasis (OPC), esophageal candidiasis, and fungal skin infections.
2. Identify symptoms of VVC, OPC, esophageal candidiasis, and fungal skin infections.
3. Identify the desired therapeutic outcomes and monitoring parameters for resolution and safety for patients with uncomplicated and complicated VVC, OPC, esophageal candidiasis, and fungal skin infections.
4. Recommend appropriate lifestyle modifications and pharmacotherapy interventions for patients with VVC, OPC, esophageal candidiasis, and fungal skin infections.
5. Recognize when long-term suppressive therapy is indicated for a patient with VVC.
6. Identify when topical versus oral treatment is indicated for a patient with OPC, esophageal candidiasis, VVC, and fungal skin infections.
7. Educate patients regarding their disease state, appropriate lifestyle modifications, and medication therapy required for effective treatment of VVC, OPC, esophageal candidiasis, and fungal skin infections.

INTRODUCTION

Superficial fungal infections, also referred to as mycoses, are common and treatable conditions seen in everyday practice. Treatment largely focuses on the use of azole and allylamine antifungal agents, either topically or orally, depending on the site, severity, and immune status of the patient.

VULVOVAGINAL CANDIDIASIS

Vulvovaginal candidiasis (VVC), whether symptomatic or asymptomatic, refers to an infection in women whose vaginal cultures are positive for *Candida* species.

EPIDEMIOLOGY AND ETIOLOGY

VVC, also known as moniliasis, is a common form of vaginitis, accounting for 20% to 25% of vaginitis cases. Although VVC is uncommon prior to menarche, an estimated 75% of women will have at least one occurrence of VVC.[1]

According to the treatment guidelines of the Centers for Disease Control and Prevention (CDC),[1] VVC can be classified as uncomplicated or complicated. Uncomplicated infections occur sporadically, cause mild-to-moderate symptoms, and occur in nonimmunocompromised women. Uncomplicated infections, most often caused by *Candida albicans*, have no identifiable precipitating cause. Complicated infections, including recurrent, severe infections, and those in women with uncontrolled diabetes, debilitation, or immunosuppression, may be caused by nonalbicans or azole-resistant fungal organisms. Recurrent VVC, defined as four or more infections per year, occurs in less than 5% of women and is distinguishable from a persistent infection by the presence of a symptom-free interval between infections.[1]

C. albicans is the primary pathogen responsible for VVC, accounting for 66% of cases. Other nonalbicans implicated pathogens include *Candida glabrata*, *Candida tropicalis*, *Candida krusei*, and *Candida parapsilosis.*[2]

PATHOPHYSIOLOGY

The normal vaginal environment protects women against vaginal infections. Under the influence of estrogen, vaginal epithelium cornifies to reduce the risk of infection. Vaginal discharge, composed of exfoliated cells, cervical mucus, and colonized bacteria, cleans the vagina. The normal pH of vaginal secretions, near 4.0, is toxic to many pathogens and is maintained by *Lactobacillus acidophilus*, diphtheroids, and *Staphylococcus epidermidis*. Alterations in the vaginal environment, including pH changes, allow for overgrowth of organisms that are normally suppressed, increasing the risk of vulvovaginitis.

RISK FACTORS

A variety of factors may increase the risk of developing symptomatic VVC in certain women (Table 85–1).

TREATMENT

The goals of treatment of VVC are as follows:

- Relief of symptoms
- Eradication of infection
- Reestablishment of normal vaginal flora
- Prevention of recurrent infections

Table 85–1

Possible Risk Factors Associated with VVC

Risk Factor	Proposed Mechanism
Broad-spectrum antibiotic use	Altered vaginal flora allowing overgrowth of *Candida* organisms; risk increases with duration of antibiotic use
Systemic corticosteroid or immunosuppressant use	Reduced vaginal protection by immunoglobulins
Sexual activity	VVC is often associated with the onset of sexual activity; partners may have penile or oral colonization; the use of vaginal irritants or devices, including diaphragms and intrauterine systems, can irritate vaginal mucosa
Tight-fitting and nonabsorbent clothing	Promotes warm, moist environment for fungus growth
Elevated estrogen levels, hormonal contraceptives, and pregnancy	Estrogen enhances *Candida* adherence to vaginal epithelial cells and yeast-mycelial transformation; this is supported by the fact that infection rates are lower before menarche and after menopause (except in women taking hormone replacement therapy), whereas rates are higher during pregnancy
Vaginal pH	Changes in glycogen and lactic acid levels
Gastrointestinal reservoir of *Candida* organisms	Transfer of organism from rectum to vagina; irritation of the vulvovaginal area during sexual intercourse may enhance invasion of organisms
Diabetes	Enhanced binding of *Candida* to epithelial cells due to hyperglycemia; asymptomatic colonization is more common in patients with diabetes; elevated sugar levels may cause conversion to symptomatic infection

VVC, vulvovaginal candidiasis.

Nonpharmacologic Treatments

Basic nonpharmacologic approaches to treatment and prevention of VVC should be recommended by the practioner in combination with pharmacologic treatment.

- Keep the genital area clean and dry
- Avoid prolonged use of hot tubs
- Avoid constrictive clothing
- Avoid vaginal douching
- Wear underwear made of breathable materials, such as cotton
- Avoid soaps and perfumes in the genital area
- Although study results are conflicting, possibly due to the strain or concentration studied, the daily consumption of active *Lactobacillus* may reduce recurrence. Newer studies have found that ingestion of *Lactobacillus rhamnosus* and *Lactobacillus reuteri* suppressed metabolic activity and killed *C. albicans*,[3] whereas older studies found no difference in infection rates in women who ingested yogurt.[4]

Pharmacologic Treatment of Uncomplicated VVC

For most cases of uncomplicated VVC, the CDC guidelines recommend a short course of therapy (1–3 days) with an oral or vaginal antifungal agent, either nonprescription or prescription.[1]

Clinical Presentation and Diagnosis of VVC

Patients with VVC may present with vulvar and/or vaginal symptoms. Symptoms often develop the week before menses and resolve with the onset of menses.

Symptoms

- Vaginal itching
- Vaginal soreness
- Vaginal burning
- Irritation
- Dysuria
- **Dyspareunia**

Signs

- Nonodorous vaginal discharge (may vary from watery to curd-like)
- Yellow or yellowish green discharge
- Erythema and edema of the labia and vulva
- Fissures
- Pustulopapular lesions
- Normal cervix

Diagnostic Testing

- Microscopic investigation for the presence of **blastospores** or **pseudohyphae**; saline wet mount has a sensitivity of 40% to 50%, whereas a potassium hydroxide (KOH) preparation has a sensitivity of 50% to 70%.[7] Asymptomatic vaginal colonization of *C. albicans* is not diagnostic of VVC since 10% to 20% of women are asymptomatic carriers of *Candida* species. Asymptomatic vaginal colonization does not require treatment; therefore, the presence alone of *Candida* should not determine care.
- Vaginal pH less than or equal to 4.5; pH should remain normal in cases of fungal infection, whereas an elevated pH suggests bacterial infection.
- *Candida* cultures should be obtained only if signs and microscopy are inconclusive or in cases of recurrent VVC.

Patient Encounter 1

A 19-year-old woman presents to your clinic complaining of itching in her vaginal area and a white discharge. After questioning the woman, you determine that she has vaginal burning, soreness, and itching, accompanied by a curd-like discharge. Although she has had vaginal infections before, she admits to recently becoming sexually active and is very concerned that she may have contracted a sexually transmitted disease. On examination, she has erythema of the labia and a nonodorous discharge.

What information is suggestive of VVC?

What additional information do you need to know before creating a treatment plan for this patient?

Nonprescription azole antifungal products are available as one-, three-, and seven-night regimens in a variety of formulations, including cream, suppository, and vaginal tablets (Table 85–2). Oral fluconazole offers the option of treatment with one dose administered without regard to time of day. Due to the risk of severe hepatotoxicity, the use of oral ketoconazole should be reserved for severe fungal infections resistant to other antifungal options.

Inability to resolve an infection may indicate a mixed infection, infection owing to a nonalbicans strain, an infection that is not fungal, or indicative of serious underlying conditions, such as diabetes or human immunodeficiency virus (HIV) infection. For these reasons, if infection does not resolve with a single antifungal course or if symptoms return within 2 months, practitioners should check cultures and further evaluate the patient's health status.

Due to the numerous treatment options available, a variety of factors can influence product selection, with patient preference playing a significant role. To improve adherence with therapy, the practitioner should discuss with the patient what options are available and what her preferences are.

Adherence rates are greater with oral treatment than with vaginal therapy, possibly due to ease of administration, short duration, and administration flexibility. Vaginal creams provide rapid relief of itching and burning, while symptom resolution may take 1 to 2 days with oral treatment. The practitioner may wish to recommend applying a vaginal cream externally to reduce itching and burning when using an oral agent, although this increases the cost of therapy. Most over-the-counter (OTC) products cost $10 to $20 per course of therapy. The cost of prescription products can vary based on insurance coverage. If the patient does not have prescription coverage, nonprescription products may prove less expensive than even one or two fluconazole tablets.

Table 85–2

Treatment Options for Uncomplicated VVC

1-Day Therapies

Butoconazole 2% sustained-release cream, 5 g intravaginally as a single application
Fluconazole 150 mg, one tablet orally as a single dose
Tioconazole 6.5% ointment, 5 g intravaginally as a single application

3-Day Therapies

Butoconazole 2% cream, 5 g intravaginally for three nights
Clotrimazole 100-mg vaginal tablet, two tablets for three nights
Miconazole 200-mg vaginal suppository, one suppository for three nights
Terconazole 0.8% cream, 5 g intravaginally for three nights
Terconazole 80-mg vaginal suppository, one suppository for three nights

7–14-Day Therapies

Boric acid 600-mg vaginal suppository, one suppository intravaginally twice daily for 14 days
Clotrimazole 1% cream, 5 g intravaginally for 7–14 nights
Clotrimazole 100-mg vaginal tablet, one tablet for seven nights
Miconazole 2% cream, 5 g intravaginally for seven nights
Miconazole 100-mg vaginal suppository, one suppository for seven nights
Nystatin 100,000-unit vaginal tablet, one tablet for 14 nights
Terconazole 0.4% cream, 5 g intravaginally for seven nights

VVC, vulvovaginal candidiasis.

▶ *Risk of Adverse Effects and Interactions*

Systemic adverse effects associated with vaginally administered azoles are less frequent than with oral products. With topical products, local discomfort such as burning, itching, stinging, and redness may occur, particularly with the first application. In contrast, common adverse effects associated with fluconazole include headache, diarrhea, nausea, dizziness, abdominal pain, and taste alterations. Around 15% of patients experience gastrointestinal side effects with orally administered fluconazole.[5]

Oral azoles are associated with significant drug interactions, particularly due to potent inhibition of cytochrome P-450 (CYP) 2C9 and moderate inhibition of CYP 3A4. For patients receiving only one dose of oral fluconazole, these interactions may not pose a significant risk but can with long-term suppressive therapy for recurrent infections.

TREATMENT OF RECURRENT VVC

The goal of treating recurrent VVC is control of the infection, rather than cure. First, any acute episodes are treated, followed by maintenance therapy. Although acute episodes of recurrent VVC will respond to azole therapy, some patients may require prolonged therapy to achieve remission. To achieve remission, 14 days of topical azole therapy or a second dose of oral fluconazole 150 mg repeated 3 days after the first dose can be used. The practitioner should consider that nonalbicans infections are more common in recurrent VVC; therefore, fluconazole and itraconazole resistance may make these agents less effective.

After achieving remission, recurrent VVC requires long-term suppressive therapy for 6 months (Table 85–3). Per CDC

Table 85–3

Treatment Options for Maintenance Therapy

Daily

Boric acid 600 mg in gelatin capsule vaginally daily during menses (5 days)
Itraconazole 100 mg orally once daily
Ketoconazole 100 mg orally once daily

Weekly

Clotrimazole 500 mg vaginal suppository once weekly
Fluconazole 100 or 150 mg orally once weekly
Terconazole 0.8% cream 5 g vaginally once weekly

Monthly

Fluconazole 150 mg orally once monthly
Itraconazole 400 mg orally once monthly

guidelines, oral fluconazole 100-, 150-, or 200-mg weekly for 6 months is first-line treatment.[1] Cessation of suppressive therapy is associated with resurgence of symptomatic infection in 30% to 50% of women.[1]

TREATMENT OF NONALBICANS INFECTIONS

Treatment response rates are lower for nonalbicans infections (eg, *C. glabrata* and *C. krusei*). Although an optimal regimen is unknown, use of nonfluconazole azole therapy for 7 to 14 days is recommended.[1] For second-line therapy, boric acid 600 mg in a gelatin capsule administered vaginally daily for 2 weeks is recommended.[1] This regimen provides mycologic cure rates of 40% to 100%,[6] although local irritation often limits its use. Oral itraconazole 200 mg twice daily 1 day per month for 6 months is also effective.[7] Other topical options include nystatin intravaginal suppositories, 100,000 U/day for 2 weeks. Topical 4% flucytosine is also effective, but use should be limited due to the potential for resistance.

VVC DURING PREGNANCY

During pregnancy, VVC may prove difficult to treat due to elevated estrogen levels, lower response rates, and frequent recurrences, accompanied by concern for the fetus. Vaginal antifungals remain the preferred treatment during pregnancy, although therapy should continue for 1 to 2 weeks to ensure effectiveness.[8] Most topical antifungals are classified as risk category C, whereas clotrimazole is classified as risk category B. Fluconazole's risk category classification for the single 150-mg dose is risk category C but category D for all other doses due to case studies of congenital limb deformities with doses of 400 to 800 mg daily during the first trimester.[9] Therefore, topical intravaginal application of clotrimazole or miconazole is generally preferred over oral antifungal therapy with fluconazole in pregnant patients.

Cultural Awareness During Treatment of VVC

As with all gynecologic issues, the practitioner is faced with cultural perceptions of female genitalia. Practitioners are treating an increased number of patients who have undergone female genital mutilation. Female genital mutilation, formerly known as female circumcision, describes the intentional alteration or injury of female genitalia. More than 100 million women and girls, particularly in Africa and the Middle East, have undergone such procedures for cultural and religious reasons.[10] Some authorities suggest using the term "genital cutting" when dealing with patients to avoid appearing judgmental.[11] Women who have undergone this procedure suffer acute and chronic complications. Patients with female genital mutilation may suffer from recurrent VVC due to inadequate drainage of vaginal fluids. Regardless of the practitioner's opinion on female genital mutilation, the practitioner must be sensitive to the patient's feeling and cultural values.

OUTCOME EVALUATION

Whether using a topical or an oral agent, patients should notice relief of itching and discomfort within 1 to 2 days. The volume of discharge should also begin to decrease within a few days. The entire course of therapy should be continued even if symptoms have resolved. If the condition recurs within 4 weeks or more than four times per year, the patient should be further evaluated

Patient Care Process: VVC

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. If patient has experienced previous VVC, determine what medications were utilized and were effective previously.
- Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Determine whether the patient is taking any substances that could interact with prescribed medications.
- Based on the medical history and lifestyle factors, determine whether the patient has compelling risk factors for VVC.
- Based on physical examination, determine whether the patient's signs and symptoms are consistent with VVC or another vaginal infection, such as a sexually transmitted infection.
- Review relevant laboratory tests, if any available, such as A1C.
- Assess the efficacy, safety, and patient adherence of current and planned pharmacotherapy.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- Select lifestyle modifications and antifungal therapy that are likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.

Implement the Care Plan:

- Educate the patient about lifestyle modifications, medication therapy, medication administration, potential adverse effects, how to manage and report adverse effects that occur, and when to anticipate improvement or seek further care.
- Address any patient concerns about VVC and its management.
- Discuss importance of medication adherence and lifestyle modifications to cure VVC and prevent recurrence.
- Determine whether the patient has insurance coverage or whether recommended agents are included on the formulary.

Follow-up: Monitor and Evaluate:

- No monitoring and evaluation is necessary unless unresolved after treatment.
- If unresolved, review medication and lifestyle modification adherence, review physical examination, and consider diagnostic laboratory to evaluate for other types of infection.

for possible non-*Candida* infections, resistant organism, or other complicating factors, along with assessment of need for long-term suppressive therapy.

OROPHARYNGEAL AND ESOPHAGEAL CANDIDIASIS

Oropharyngeal candidiasis (OPC) is a common fungal infection, often associated with immune suppression (ie, HIV infection, diabetes, and malignancies). If left untreated, it will progress to more serious oral disease, such as esophageal candidiasis.

EPIDEMIOLOGY AND ETIOLOGY

The occurrence of oropharyngeal and esophageal candidiasis is an indicator of immune suppression, often developing in infants, the elderly, and the immunocompromised. One-third to one-half of geriatric inpatients develop OPC. Denture stomatitis is present in approximately 40% of denture wearers,[12] more commonly in women than men. Oral candidiasis is the most commonly reported adverse drug event reported by patients receiving inhaled corticosteroids,[13] with the prevalence of esophageal candidiasis reaching 37% among patients treated with inhaled corticosteroids.[14] The incidence of esophageal candidiasis is highest among patients receiving high doses of corticosteroids or those with diabetes.

The prevalence of HIV infection plays a significant role in the incidence of oropharyngeal and esophageal candidiasis. In the 1980s, the incidence of OPC increased fivefold, in association with the spread of HIV infections.[15] Although HIV infection remains a risk factor for candidiasis, the introduction of highly active antiretroviral therapy caused a decline in the incidence of oral candidiasis to 45.9% to 79.1%, varying by geographic location, race, and therapy.[16]

OPC remains the most common opportunistic infection in patients with HIV. For the majority of patients, it is the first manifestation of HIV infection.[18] The incidence of oropharyngeal infection increases with decreasing CD4+ lymphocyte counts and is most often observed when CD4+ counts are less than 200 cells/mm^3 (350 × 106/L). An incidence of 59% is observed in patients with a CD4+ count less than 350 cells/mm^3 (350 × 106/L).[17]

Esophageal candidiasis usually occurs in patients with lower CD4+ counts than those that develop OPC.[21] Although esophageal candidiasis represents the first manifestation of HIV infection in less than 10% of cases, it is the most common acquired immunodeficiency syndrome (AIDS)-defining disease.[18] The CDC classifies esophageal candidiasis as a Stage 3–defining opportunistic infection in HIV.[19] As with OPC, the incidence of esophageal candidiasis increases with decreasing CD4+ counts and, therefore, is a measure of declining CD4+ count or treatment failure.

C. albicans accounts for 80% of cases of OPC and esophageal candidiasis. Over the last 20 years, an increasing incidence of *C. albicans* resistance has been accompanied by an increased incidence of nonalbicans species infections, including *C. glabrata, C. tropicalis, C. krusei*, and *C. parapsilosis*. In patients with cancer and HIV, the prevalence of *C. glabrata* infections or mixed *C. albicans* and *C. glabrata* infection has been increasing.[20] Such infections tend to be more severe and require larger doses of antifungal agents for treatment.

PATHOPHYSIOLOGY

Similar to VVC, the development of OPC occurs when the normal environment is altered. *Candida* organisms frequently colonize the oropharynx and mucous membranes. These organisms do not become pathogenic until the environmental balance is disturbed. This occurs in the setting of broad-spectrum antibiotic use, tissue damage (due to chemotherapy, catheter tubing, trauma, or smoking), hyposalivation, or immune deficiency.

Table 85–4

Risk Factors for Oropharyngeal and Esophageal Candidiasis

Factor	Proposed Mechanism
Extremes of age	Immature immunity in infants and reduced immunity in the elderly
Impaired mucosal integrity	Breaks in the protective barrier allows fungal invasion; often due to radiation, surgery, or mucositis
Dentures	Adherence of fungus to dentures, along with reduced salivary flow under dentures; ill-fitting dentures may impair mucosal integrity
Xerostomia	Reduced cleansing and defense factors of saliva
Use of antibiotics	Altered flora of mucosa allowing fungal overgrowth
Use of steroids	Suppression of immunity
Use of immunosuppressant	Suppression of immunity
HIV infection	Decreased CD4 T lymphocytes
Diabetes mellitus	Elevated glucose levels and defense factors in saliva
Nutritional deficiencies	Altered defense mechanisms, impaired mucosal integrity, or enhanced pathogenic potential of fungus

HIV, human immunodeficiency virus.

RISK FACTORS

Risk factors for OPC can be found in Table 85–4.

CLINICAL PRESENTATION AND DIAGNOSIS

See text boxes for clinical presentation and diagnosis of OPC and esophageal candidiasis.

TREATMENT

Along with selecting an effective treatment, selection of an appropriate antifungal agent requires consideration of location and severity of infection, medication adherence, potential drug interactions, concomitant medical conditions, and presence of sucrose or dextrose. Topical agents require frequent dosing and prolonged contact time with oral mucosa. Rough surfaces of tablets and troches may irritate sensitive mucosa. Patients with **xerostomia** may have inadequate saliva to dissolve troches. Topical agents containing sucrose or dextrose may increase the risk of caries or cause elevated blood sugar in patients with diabetes. Along with being expensive, oral azoles exhibit an increased risk of toxicity and drug interactions due to inhibition of CYP-450.

Because oropharyngeal and esophageal candidiasis are signs of an immunocompromised state, the immune status of the patient should be considered in the therapeutic care plan. For HIV-infected patients, this should also include an evaluation of the patient's antiretroviral therapy because fungal infections may represent immune status deterioration.

Clinical Presentation and Diagnosis of Oropharyngeal Candidiasis

OPC is often a presumptive diagnosis based on signs and symptoms, along with the resolution of them after treatment with antifungal agents.

Symptoms

- Sore, painful mouth, and tongue
- Burning tongue
- **Dysphagia**
- Metallic taste/loss of taste

Signs

Signs vary depending on the type of oropharyngeal candidiasis.

- Diffuse erythema on the surface of buccal mucosa, throat, tongue, and gums
- White patches on tongue, palate, gums, or buccal mucosa; removal of patches reveals erythematous and bloody tissue; ability to remove patches distinguishes OPC from oral hairy leukoplakia
- Angular cheilitis presents with small cracking lesions, erythema, and soreness at the corners of the mouth; associated with vitamin and iron deficiency
- Denture stomatitis presents with flat, red lesions on mucosa beneath dentures, signs of chronic erythema and edema on mucosa
- Hyperplastic OPC presents with discrete, transparent raised lesions on the inner mucosa of the cheek; typically found in men who smoke
- Pseudomembranous OPC presents with yellow-white plaques that may be small and discrete or confluent; the most common form found in HIV patients

Diagnostic Testing

Diagnosis is primarily based on identification of characteristic lesions and confirmed by scraping of lesions to perform a gram-stain. Although rarely necessary, diagnostic testing is possible if a definitive diagnosis is required.

- Cytology, although presence of *Candida* is not diagnostic because colonization is common
- Culture to identify species of yeast or presence of resistance
- Biopsy

Clinical Presentation and Diagnosis of Esophageal Candidiasis

Symptoms

- Fever
- **Odynophagia**
- Dysphagia
- Retrosternal pain

Signs

- Fever
- Hyperemic or edematous white plaques
- Ulceration of esophagus
- Increased mucosal friability
- Narrowing of lumen

Diagnostic Testing

Unlike OPC, diagnosis of esophageal candidiasis is not based solely on clinical presentation, instead requiring endoscopic visualization of lesions and culture confirmation. Due to the invasive nature of these procedures, most practitioners opt to treat the infection presumptively, reserving endoscopic evaluation for patients who fail therapy.

- Cytology and culture to identify species of yeast or presence of resistance
- Barium esophagogram
- Endoscopy revealing whitish plaques with progression to superficial ulceration of the esophageal mucosa
- Mucosal biopsy

For low-risk patients, topical agents are first-line therapy for OPC, although systemic agents may be used for severe or unresponsive cases. Infectious Disease Society of America (IDSA) guidelines recommend clotrimazole troches, 10 mg five times per day, or miconazole mucoadhesive buccal 50 mg tablet for 7 to 14 days for mild infections. Alternatives for mild infections include nystatin suspension or pastilles four times daily.[21] Once-daily oral fluconazole 100 to 200 mg for 7 to 14 days is reserved for moderate-to-severe cases.[21] Two weeks of oral itraconazole 200 mg or posaconazole 400 mg daily, voriconazole 200 mg twice daily, or amphotericin-B suspension four times daily are alternatives, typically reserved for refractory cases. For refractory cases additional therapy options include intravenous echinocandin or intravenous amphotericin-B deoxycholate but are considered second-line due to lack of concentration of drug at the site of infection.

For non–HIV-infected patients who have suppressed immune systems, the practitioner must consider the patient's risk of dissemination. Patients with cell-mediated immune deficiency but near-normal granulocyte function, such as patients with diabetes, solid organ transplant, or solid tumors, are at low risk for dissemination. The risk of dissemination is higher in patients who develop neutropenia, including patients with leukemia or bone marrow transplant. These patients should be treated aggressively to prevent invasive fungal infection.

For the treatment of OPC in HIV-infected individuals, initial episodes can be adequately controlled with topical agents, such as clotrimazole troches, so long as symptoms are not severe and no esophageal involvement is suspected.

Representing a severe extension of OPC, esophageal candidiasis requires systemic antifungal therapy. The significant morbidity associated with esophageal candidiasis warrants aggressive treatment.

Unlike OPC, which can be treated with topical agents, esophageal candidiasis requires systemic antifungal therapy for effective treatment.[18] The IDSA recommends oral fluconazole for 7 to

Patient Care Process: Oropharyngeal Candidiasis

Collect Information:

- Assess the patient's symptoms to determine whether symptoms are consistent with oropharyngeal or esophageal candidiasis.
- Evaluate for risk factors, such as immunocompromised state
- Review the medical history. Does the patient have compelling indications or contraindications for specific antifungal treatment?
- Review any available diagnostic data, including cultures.
- Review available laboratory tests, especially liver function.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use. Is the patient taking any medications that may contribute to candidiasis? Is the patient taking any medications that may interfere with treatment?
- Determine if the patient has any allergies.

Assess the Information:

- If the patient has had oropharyngeal or esophageal candidiasis previously, determine what treatments were helpful to the patient in the past.
- If the patient has had oropharyngeal or esophageal candidiasis previously, determine whether the patient has risk factors for recurrent infection.
- Determine whether long-term suppressive therapy is necessary.
- Evaluate the patient for the potential of adverse drug reactions, drug allergies, or drug interactions.

Develop a Care Plan:

- Select antifungal therapy that is likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.
- Discuss warning signs to report, include, worsening symptoms or recurrence.

Implement the Care Plan:

- Stress the importance of adherence with the antifungal regimen until complete.
- Provide patient education pertaining to oropharyngeal or esophageal candidiasis and antifungal therapy, including causes, risk factors, medication administration, potential adverse effects, and potential medication interactions.
- Discuss warning signs to report, include worsening symptoms or recurrence.

Follow-up: Monitor and Evaluate:

- Follow-up if symptoms do not resolve within 7 days or if symptoms worsen.
- Follow up on any identifiable precipitating cause, such as an immunocompromised state.

14 days in patients with esophageal candidiasis and moderate-to-severe disease, with an echinocandin or amphotericin-B as alternatives in patients unable to tolerate oral therapy, or with resistant or refractory disease.[21] Itraconazole 200-mg daily, posaconazole 400-mg twice daily, voriconazole 200-mg twice daily, and intravenous fluconazole are considered second-line therapy. If immunocompromised patients experience frequent or severe recurrences, particularly of esophageal candidiasis, chronic maintenance therapy with fluconazole 100 to 200 mg daily should be considered.

Patient Encounter 2, Part 1

A 35-year-old man presents to your clinic complaining of "burning and soreness in my mouth" along with a metallic taste and "this funny white stuff." On initial examination, he has white patches on his tongue, gums, and buccal mucosa. These patches are easily removed, revealing erythematous tissue underneath. Although he has visited the clinic before, his medical records are incomplete. He denies any current or recent medication use or being HIV-positive.

What additional information do you need to know before creating a treatment plan for this patient?

What underlying medical conditions might make him susceptible to fungal infections?

OUTCOME EVALUATION

Patients should notice symptomatic relief within 2 to 3 days of initiating therapy. Complete resolution typically occurs within 7 to 10 days. The entire course of therapy should be continued even if symptoms have resolved. If the condition worsens or does not resolve, the patient should be referred to a specialist for aggressive therapy.

Short courses of oral azoles are associated with gastrointestinal upset, whereas courses lasting longer than 7 to 10 days are associated with increased risk of hepatotoxicity and CYP-450 drug interactions. In patients receiving prolonged therapy lasting more than 3 weeks, baseline and periodic monitoring of liver function tests should be considered.

Immunocompetent patients generally do not require reassessment after treatment. Patients with neutropenia exhibit an increased risk of dissemination of infection and, therefore, should be monitored for signs of systemic fungal infection. Due to an increased risk of recurrence, HIV-positive patients should routinely be evaluated for recurrence at each visit.

Patient Encounter 2, Part 2

How is the treatment care plan altered if the patient has a history of frequent and severe OPC? If the patient is HIV-positive? If the patient is neutropenic?

MYCOTIC INFECTIONS OF THE SKIN, HAIR, AND NAILS

Tinea infections are superficial fungal infections in which the pathogen remains within the keratinous layers of the skin or nails (Table 85–5). Typically, these infections are named for the affected body part, such as tinea pedis (feet), tinea cruris (groin), and tinea corporis (body). Tinea infections are commonly referred to as ringworm due to the characteristic circular lesions. In actuality, tinea lesions can vary from rings to scales and single or multiple lesions.

EPIDEMIOLOGY AND ETIOLOGY

Tinea infections are the second most frequently reported skin condition. The common tinea infections are tinea pedis, tinea corporis, and tinea cruris. Tinea pedis, the most prevalent cutaneous fungal infection, impacts more than 25 million people annually in the United States.

Fungal skin infections are primarily caused by **dermatophytes** such as *Trichophyton*, *Microsporum*, and *Epidermophyton*. *Trichophyton rubrum* accounts for more than 75% of all cases in the United States.[22] To a lesser extent, *Candida* and other fungal species cause skin infections. With tinea infections, the

Table 85–5

Signs, Symptoms, and Risk Factors of Superficial Fungal Infections

Infection	Symptoms, Signs, and Risk Factors
Tinea pedis	• Involves plantar surface and interdigital spaces of foot • Interdigital infections produce itching; presents as fissures, scaling, or macerated skin; can occur between any toes but most often between fourth and fifth toes; may cause foul smell due to superinfection with *Pseudomonas* or diphtheroids • Hyperkeratotic infections present with slivery white scales on a thickened, red base; usually covers entire foot; occasionally may also affect hand • Vesiculobullous tinea pedis presents as pustules or vesicles on soles of feet; associated with maceration, itching, and thickening of sole; may cause lymphangitis and cellulitis; most common during summer months • Ulcerative tinea pedis presents as macerated, denuded, and weeping ulcers on soles; may produce extreme pain and erosion of interdigital spaces; typically complicated by opportunistic gram-negative infections • Risk factors include occlusive footwear, foot trauma, and use of public showers
Tinea manuum	• Infection of the interdigital and palmar surfaces • Presents as white scales in palmar folds; may also develop scales on remainder of palm; may present as singular plaque • More commonly affecting only one hand • Presents with hyperkeratotic skin
Tinea cruris	• Presents with follicular papules and pustules on the medial thigh and inguinal folds • Ringed lesions may extend from inguinal fold over adjacent inner thigh • Lesions usually spare the penis and scrotum, in contrast to candidiasis • Frequency increases during summer • Primarily develops in young men • Risk factors include tight-fitting clothing, excessive sweating, poor hygiene, increased humidity and temperatures • Commonly referred to as "jock itch"
Tinea corporis	• Presents with circular, scaly patch with enlarged border • Lesions may have red papules or plaque in center that clears, leaving hypopigmentation or hyperpigmentation • Itching may be present • Commonly referred to as ringworm of the body • Risk factors include animal to human contact
Tinea versicolor	• Characterized by skin depigmentation but can present as hyperpigmentation, particularly in dark-skinned patients • Typically occurs in areas with sebaceous glands, including neck, trunk, and arms • Depigmentation may persist for years • Primarily develops in young and middle-aged adults • Risk factors include application of oil, greasy skin, high ambient temperature, high relative humidity, tight-fitting clothing, immunodeficiency, malnutrition, hereditary predisposition
Tinea barbae	• Infection of beard area
Tinea capitis	• Infection of the head and scalp • May be asymptomatic initially, then progresses to inflammatory alopecia • "Black dot" alopecia may develop due to breakage of hair at the root • May form kerions (nodular swellings) • Scaling or favus may develop on scalp • Cervical lymphadenopathy is common • Primarily found in infants, children, and young adolescents, often in African American and Hispanic populations • Can be spread from person to person or animal to person
Onychomycosis (tinea unguium)	• Infection of nail plate and bed • Nail becomes opaque, thick, rough, yellow or brownish, and friable; nail may separate from bed • Toenails affected more frequently than fingernails • Prevalence increases with advanced age

causative dermatophyte typically invades the stratum corneum without penetration into the living tissues, leading to a localized infection.

PATHOPHYSIOLOGY

The primary mode of transmission of tinea infections is direct contact with other persons or surface reservoirs. Upon contact, the dermatophytes attach to the keratinized cells, leading to thickening of the cells. Although infection remains localized, bacterial superinfections may develop.

The pathophysiology of onychomycosis depends on the clinical type. With the most common form of onychomycosis, distal lateral subungual, the fungus spreads from the plantar skin. The fungus invades the underside of the nail through the distal lateral nail bed, leading to inflammation of the area. In cases of white superficial onychomycosis, the fungus invades the surface of the nail plate directly. With white superficial onychomycosis, the nail bed and hyponychium are infected secondarily. Proximal subungual onychomycosis infections begin in the cuticle and the proximal nail fold, then penetrate the dorsum of the nail plate.

RISK FACTORS

- Prolonged exposure to sweaty clothing
- Excessive skin folds
- Sedentary lifestyle
- Warm, humid climate
- Use of public pools
- Walking barefoot in public areas
- Skin trauma
- Poor nutrition
- Diabetes mellitus
- Immunocompromised state
- Impaired circulation

Clinical Presentation and Diagnosis of Mycotic Infections

Symptoms and Signs

See Table 83–5.

Diagnostic Testing

- KOH prep
- Wood's ultraviolet lamp
- Microscopic examination
- Fungal cultures
- Periodic acid-Schiff (PAS) staining of nail

Treatment of Skin and Hair Infections

The goals of treatment include the following:

- Providing symptomatic relief
- Resolution of infection
- Preventing spread of infection

TREATMENT

Nonpharmacologic Therapy

- Because fungi thrive in warm, moist environments, the practitioner should encourage patients to wear loose-fitting clothing and socks, preferably garments made of cotton or other fabrics that wick moisture away from the body. Avoid clothing made with synthetic fibers or wool.
- Sweaty or wet clothing should be removed as soon as possible.
- Clean the infected area daily with soap and water.
- The infected area should be dried completely prior to dressing, paying particular attention to skin folds.
- To allow circulation of air, the infected area should not be bandaged.
- For foot infections, cotton socks are recommended, although these should be changed two to three times a day to reduce moisture.
- To prevent spread, towels, clothing, and footwear should not be shared with other persons.
- Wear protective footwear in public showers and pool areas.

Pharmacologic Therapy of Tinea Infections

Since dermatophyte hyphae seldom penetrate into the living layers of the skin, instead remaining in the stratum corneum, most infections can be treated with topical antifungals. Infections covering large areas of the body, infections involving nails or hair, chronic infections, or infections not responding to topical therapy may require systemic therapy. Treatment is typically initiated based on symptoms, rather than on microscopic evaluation. For infections accompanied by inflammation, combination therapy with a topical steroid can be considered (Tables 85–6, 85–7, and 85–8).

Typically, tinea pedis requires treatment one to two times daily for 4 weeks, whereas tinea corporis and tinea cruris require topical treatment one to two times daily for 2 weeks. When applying treatment, the medication should be applied at least 1 inch beyond the affected area. Treatment of infection should continue at least 1 week after resolution of symptoms. Many practitioners opt to initiate therapy with nonprescription clotrimazole, tolnaftate, miconazole, or terbinafine, reserving prescription topical agents, such as naftifine, ciclopirox, and butenafine, for second-line therapy or refractory cases and systemic therapy for refractory cases.

When recommending topical therapy, the selection of vehicle is based on the type of lesion and location of the infection. Solutions and lotions are recommended for hairy areas and oozing lesions, whereas creams and ointments should be avoided in these areas. Creams are better for moderately scaling and nonoozing lesions. For hyperkeratotic lesions, ointments can be considered. The selected formulation should be applied to the affected area after it is cleaned and dried. The medication should be rubbed into the infected area for improved penetration. Because most patients do not rub in sprays and powders, penetration of the epidermis is minimal, making them less effective than other formulations. Sprays and powders should be considered adjuvant therapy with a cream or lotion or as prophylactic therapy to prevent recurrence.[7] For OTC medications, in addition to formulation, it is important to identify the active ingredient desired. Even products with the same brand name may contain different active ingredients. Due to the severity of infection and inflammation,

tinea capitis does not adequately respond to topical agents; therefore, oral agents for 6 to 8 weeks are recommended. Griseofulvin has long been considered the treatment of choice due to its ability to achieve high levels within the stratum corneum.[23] Terbinafine and itraconazole have also demonstrated effectiveness.[23] Due to its lipophilicity, itraconazole achieves high dermal concentrations that are maintained for 4 weeks after discontinuation of therapy.[24]

Treatment of Onychomycosis

For onychomycosis, a chronic infection that rarely remits spontaneously, adequate treatment is essential to prevent spread to other sites, secondary bacterial infections, cellulitis, or gangrene.

Due to the chronic nature and impenetrability of nails, topical agents have low efficacy rates for treating onychomycosis. Oral agents that can penetrate the nail matrix and nail base, such as itraconazole and terbinafine, are more effective than ciclopirox lacquer, efinaconazole solution, or tavaborole solution. Itraconazole (200 mg twice daily for 1 week per month or 200 mg daily for 12 weeks) and terbinafine (250 mg daily for 12 weeks) demonstrate mycological cure rates of 71% and 77%, respectively, whereas the cure rate range from 29% to 36% for ciclopirox, approximately 55% for efinaconazole, and 35% for tavaborole.[25] For patients with liver disease or who are unable to use oral agents, ciclopirox lacquer, efinaconazole solution, and tavaborole solution remain reasonable alternatives, despite requiring 48 weeks of therapy. Due to low efficacy, griseofulvin should only be considered second-line therapy with therapy continued for 4 months for fingernail infections or 6 months for toenail infections.

There is a small risk of developing congestive heart failure with itraconazole therapy due to its negative inotropic effects.[26] Itraconazole should not be administered to patients with ventricular dysfunction such as congestive heart failure. The Food and Drug Administration (FDA) also released warnings that itraconazole and terbinafine are associated with serious hepatic toxicity, including liver failure and death. Liver failure associated with these medications has occurred in patients with no preexisting liver disease or serious underlying medical conditions. Treatment with itraconazole or terbinafine for prolonged periods requires laboratory monitoring of liver function tests before initiation of therapy and at monthly intervals.

Cultural Awareness When Treating Mycotic Infections

Awareness of cultural beliefs related to feet and hands is essential when treating patients with fungal infections. In Arab countries, showing the bottom of the foot is a grave insult. The foot is

Table 85–7

Dosing of Topical Agents for Tinea Infections and Onychomycosis

Agents	Topical Dosing Frequency
Butenafine	Once daily
Ciclopirox	Twice daily; at bedtime (lacquer)
Clotrimazole	Twice daily
Econazole	Once daily
Efinaconazole	Once daily (nail solution)
Haloprogin	Twice daily
Ketoconazole	Once daily
Miconazole	Twice daily
Naftifine	Once daily (cream); twice daily (gel)
Oxiconazole	Twice daily
Sertaconazole	Twice daily
Sulconazole	Twice daily
Tavaborole	Once daily (nail solution)
Terbinafine	Twice daily
Tolnaftate	Two to three times daily

Table 85–8

Dosing of Systemic Therapy for Tinea Infections

Medication	Adult Dosing	Pediatric Dosing
Fluconazole	150 mg/week	6 mg/kg/week
Griseofulvin	0.5–1 g/day	10–20 mg/kg/day
Itraconazole	200 mg twice daily	Not studied
Ketoconazole	200–400 mg/day	3.3–6.6 mg/kg/day
Terbinafine	250 mg/day	< 25 kg: 125 mg/day; 25–35 kg: 187.5 mg/day; > 35 kg: 250 mg/day

Patient Care Process: Mycotic Infections—1

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. If patient has experienced previous tinea infections, determine the location of that infection and what medications were utilized and were effective previously.
- Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Determine whether the patient is taking any substances that could interact with prescribed medications.
- Based on the medical history and lifestyle factors, determine whether the patient has compelling risk factors for tinea infections.
- Based on physical examination of affected area, determine whether the patient's signs and symptoms are consistent with a superficial fungal infection.
- Review relevant laboratory tests, if any are available.
- Assess the efficacy, safety, and patient adherence of current and planned pharmacotherapy.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- Select lifestyle modifications and antifungal therapy that are likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.

Implement the Care Plan:

- Educate the patient about lifestyle modifications, medication therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about the tinea infection and its management.
- Discuss importance of medication adherence and lifestyle modifications to cure tinea pedis, cruris, or corporis and prevent fungal infection recurrence.
- Determine whether the patient has insurance coverage or whether recommended agents are included on the formulary.

Follow-up: Monitor and Evaluate:

- No monitoring and evaluation is necessary for short-course therapy unless unresolved. For courses lasting longer than 6 weeks in children, baseline alanine aminotransferase (ALT) and aspartate aminotransferase (AST) measurements are recommended, along with complete blood count (CBC) at 6 weeks.
- If unresolved, review medication and lifestyle modification adherence, review physical examination, and consider diagnostic laboratory to evaluate for other types of infection.

Patient Care Process: Mycotic Infections—2

Collect Information:

- Assess the patient's symptoms to determine whether self-treatment with OTC antifungal therapy is appropriate. Exclusions for self-treatment include infection of nails or hair, unsuccessful initial treatment, worsening condition, signs of secondary bacterial or systemic infection, large infected areas, or chronic medical conditions such as diabetes, immunosuppression, or impaired circulation.
- Review any available diagnostic data, including cultures and KOH preps.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use.
- Any allergies?

Assess the Information:

- If the patient has had a mycotic infection previously, determine what treatments were helpful to the patient in the past.
- Determine whether long-term prophylactic therapy is necessary to prevent recurrence.
- Determine whether the patient has prescription coverage.

Develop a Care Plan:

- Evaluate the patient for the potential for adverse drug reactions, drug allergies, and drug interactions.
- Select lifestyle modifications and antifungal therapy that are likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.

Implement the Care Plan:

- Educate the patient on lifestyle modifications that will prevent recurrence, including keeping the area dry, wearing shower shoes, washing clothing in hot water, using drying powders, avoiding sharing towels or clothing, and wearing loose-fitting clothing.
- Provide the patient education pertaining to mycotic infections and antifungal therapy, including causes, medication application or administration, length of therapy, how to avoid spread of infection or recurrence, and potential adverse effects.
- Discuss dietary modifications that are necessary with oral agents.
- Discuss medications that may interact with antifungal therapy, particularly with oral agents used for nail infections.
- Discuss warning signs to report such as recurrent or difficult-to-cure infections, infections with malodorous discharge or bleeding.
- Stress the importance of adherence with the antifungal regimen.

Follow-up: Monitor and Evaluate:

- Follow-up if unresolved or worsens with treatment.

considered the dirtiest part of the body. As such, patients from these countries may be hesitant to show their feet to the practitioner. In other countries, the open palm "high five" gesture is considered insulting. When treating patients with infections on the hand, the practitioner should refrain from making this gesture while discussing the patient's hand infection.

OUTCOME EVALUATION

For infections of the skin, patients should notice relief of symptoms, including pruritus, scales, and inflammation, within 1 to 2 weeks. Therapy should be continued at least 1 week after complete resolution of symptoms. If the condition worsens on topical therapy, the patient should be treated with oral therapy.

For onychomycosis, relief of symptoms is slow. The infected nail will need months to grow out. The practitioner should advise the patient not to become frustrated by the slow resolution. Despite the slow progress, the antifungal agent is curing the infection. The practitioner should also advise the patient that even after the infection is cured, the nail may not look "normal."

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
CDC	Centers for Disease Control and Prevention
HIV	Human immunodeficiency virus
KOH	Potassium hydroxide
OPC	Oropharyngeal candidiasis
OTC	Over-the-counter
PAS	Periodic acid-Schiff test
VVC	Vulvovaginal candidiasis

Invasive Fungal Disease

Jeffrey M. Rybak

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Differentiate epidemiologic differences and host risk factors for acquisition of primary and opportunistic invasive fungal diseases.
2. Recommend appropriate empiric or targeted antifungal therapy for the treatment of invasive fungal diseases.
3. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for invasive fungal infections.
4. Evaluate the role of antifungal prophylaxis in the prevention of opportunistic fungal diseases.

INTRODUCTION

Invasive fungal infections or invasive mycoses are general terms for diseases caused by the invasion of living tissue by fungi. In contrast to superficial mycoses (see Chapter 85), invasive fungal infections are less common but are of greater medical concern because of their disproportionately higher severity and mortality. Approximately 1.5 million people die each year from the 10 most common invasive fungal infections, which is higher than World Health Organization mortality estimates for tuberculosis (1.4 million) or malaria (1.2 million).[1] However, these numbers likely underestimate the actual mortality burden of invasive fungal infections considering that the four most common infections (cryptococcosis, invasive candidiasis, invasive aspergillosis [IA], and *Pneumocystis jiroveci* pneumonia) are often underdiagnosed and not reportable diseases to public health agencies (Table 86–1).

Invasive fungal diseases are broadly categorized as either primary or opportunistic mycoses. **KEY CONCEPT** Primary invasive fungal diseases develop following exposure to fungal spores or conidia in the soil that, when disturbed, can become aerosolized and inhaled leading to infection, even in an immunocompetent patient exposed to a sufficient inoculum. Because these fungi are in specific soil types in select geographic areas, they are also referred to as endemic fungi. In the United States, three species (*Histoplasma capsulatum*, *Blastomyces dermatitidis*, and *Coccidioides immitis/Coccidioides posadasii*) account for most of these infections (see Table 86–1).

KEY CONCEPT In contrast, opportunistic fungal diseases are most frequently encountered in the setting of compromised host immune defenses and are caused by a wider spectrum of less virulent fungal species that rarely cause infection in healthy patients (see Table 86–1). Hence, the spectrum, severity, and outcome of opportunistic fungal diseases are strongly influenced by the degree, type, and severity of host immunosuppression. As a rule, opportunistic fungal diseases are difficult to diagnose, but often fatal if not diagnosed early and treated aggressively.

Occasionally, opportunistic fungal diseases may be associated with outbreaks in nonimmunocompromised patients if fungi are inadvertently inoculated into patients from contaminated drug solutions or medical devices. In 2012, an outbreak of fungal meningitis and joint infections ($n = 751$ cases) in 20 states was eventually traced by the Centers for Disease Control and Prevention and state health departments to contaminated preservative-free methylprednisolone solution compounded by a pharmacy that was distributed to multiple doctors' offices. These contaminated steroid solutions were administered as epidural and articular injections in patients with chronic back or joint pain. The dematiaceous mold eventually linked to the fungal meningitis cases, *Exserohilum rostratum*, had rarely been described as a human pathogen prior to the outbreak.[2]

PRIMARY (ENDEMIC) MYCOSES

EPIDEMIOLOGY AND ETIOLOGY

Endemic mycoses are capable of infecting otherwise healthy individuals. In immunocompromised patients, endemic fungal infections present with more severe manifestations or can reactivate with life-threatening consequences. Because initial symptoms of an endemic fungal infection are nonspecific and produce symptoms indistinguishable from other slowly progressing infections (tuberculosis), a careful patient history concerning travel and activities that may have resulted in exposure to endemic fungi is essential for early diagnosis.

Two of the most common endemic fungal infections (histoplasmosis and North American blastomycosis) are found in overlapping regions in the eastern and central river basins of the United States (Figure 86–1). *H. capsulatum* var. *capsulatum*, the causative fungus of histoplasmosis, grows heavily in soil contaminated with bird or bat excreta, which serves to enhance sporulation of the fungus.[3,4] Infections have been associated with activities that disturb soil contaminated with this excreta, including cave

Table 86–1

Invasive Mycoses

Primary (Endemic) Invasive Fungi
Histoplasma capsulatum[a]
Coccidioides immitis/Coccidioides posadasii[a]

[a]Most common.

Patient Encounter 1, Part 1: Endemic Fungal Infection

A 32-year-old man from Cincinnati, Ohio presents with influenza-like symptoms, including mild fever and persistent cough, 2 months after working on renovating a structure on his property. The patient has had persistent symptoms 3 weeks despite a recent 2-week course of amoxicillin/clavulanate. He is otherwise healthy and does not take any chronic medications. Chest computed tomography (CT) found mediastinal and hilar lymphadenopathy as well as multiple pulmonary nodules.

What information is suggestive that this patient may have an endemic fungal infection?

What is the most likely endemic fungal pathogen based on this patient's area of residence?

exploration (spelunking), working in or demolishing chicken coops or older buildings, or work in campsites in heavily wooded areas. For blastomycosis, decaying organic matter, warm humid conditions, and proximity to water or frequent rainfall support growth of this fungus. Outbreaks of blastomycosis have been most frequently associated with occupational or recreational activities around the major waterways such as the Great Lakes region, where soil concentrations of *B. dermatitidis* are elevated.[4]

Coccidioidomycosis differs from histoplasmosis and blastomycosis, as the fungus is associated with arid to semiarid climates, hot summers, low altitude, alkaline soil, and sparse flora. Hence the fungus is found in the Southwestern region of the United States stretching from Western Texas to Southern California (see Figure 86–1).[5] Epidemics of coccidioidomycosis have been reported in California following dust storms and earthquakes, including cycles of intense drought and rain, which favor the growth of the fungus and dispersal of its spores, called arthroconidia.

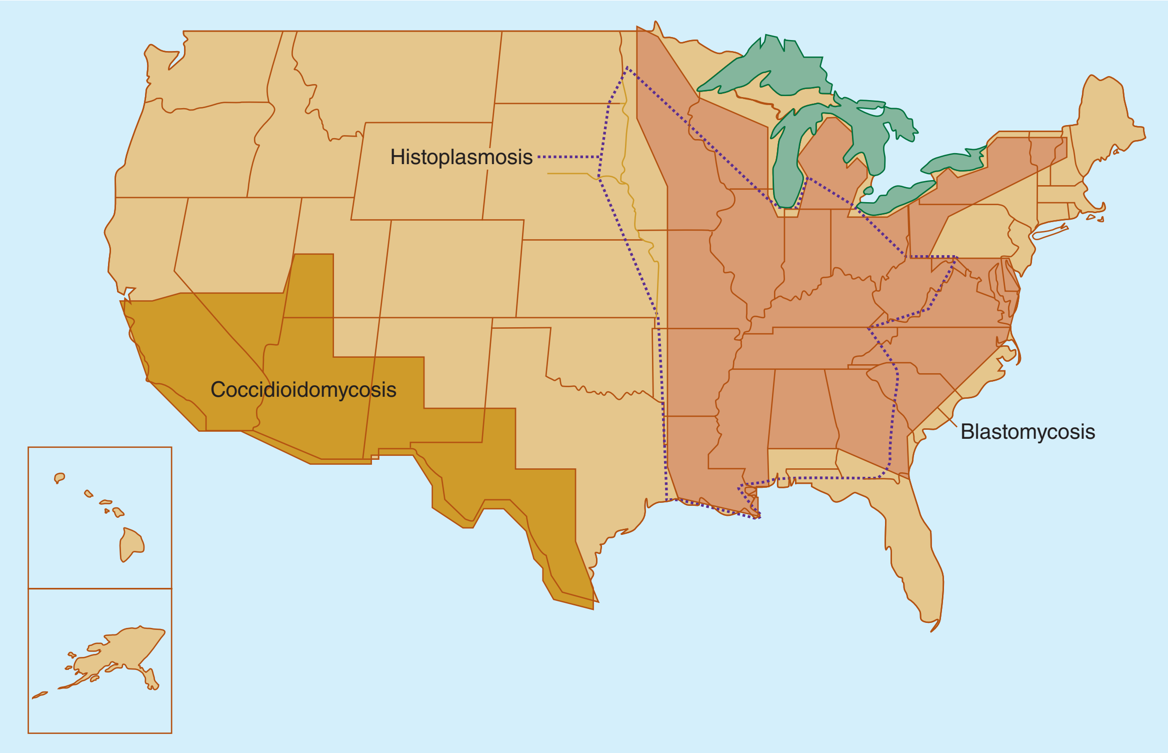

FIGURE 86–1. Geographic localization of primary (endemic) fungi in the United State.

PATHOPHYSIOLOGY

Endemic fungi share several characteristics that contribute to their pathogenicity in humans. All endemic fungi exhibit temperature-dependent dimorphism, meaning they can propagate as either yeast (single cells that reproduce by budding into daughter cells) or molds (multicellular filamentous fungi that reproduce through the production of conidia or spores). At environmental temperatures (25–30°C [77–86°F]), *H. capsulatum*, *B. dermatitidis*, and *C. immitis* grow in the mold form, producing 2- to 10-μm round- to oval-shaped (*Histoplasma* and *Blastomyces*) or barrel-shaped **conidia** (*Coccidioides*) that are dispersed throughout the environment and in air currents. At physiologic temperatures, the conidia germinate into yeast (*Histoplasma* and *Blastomyces*) or specialized cell forms called spherules (*Coccidioides*) that are resistant to killing by alveolar macrophages and neutrophils in the lung.

Control of infection by the host requires the development of antigen-specific T-lymphocyte response that enhances macrophage fungicidal activity and formation of a **granuloma** to contain the fungus.[6] Not surprisingly, patients with T-cell–mediated immune deficiency (eg, acquired immunodeficiency syndrome [AIDS] patients and transplant recipients requiring immunosuppressive therapy) or suppressed cellular immunity due to drug therapy (eg, chemotherapy, high-dose corticosteroids, or tumor necrosis–α blockers such as infliximab) are at higher risk for reactivation of fungal disease.

The most common route of infection for endemic fungi is the respiratory tract, where conidia aerosolized from contaminated soil are inhaled into the lung. Once in the lung, conidia are phagocytosed but not destroyed by macrophages and neutrophils in the alveoli and bronchioles. Within 2 to 3 days, conidia germinate into yeast resistant to phagocytosis and killing by macrophages and neutrophils (Figure 86–2A and B). For *C. immitis*, germination of the arthroconidia results in the formation of a sac-like structure called a spherule filled with endospores (Figure 86–2C). Spherules then rupture to release large numbers of endospores, which are the propagating form of the infection. Control of infection in the lungs requires the formation of a granuloma to contain the fungus. However, patients exposed to an overwhelming inoculum or a lower inoculum exposure in the setting of suppressed T-cell–mediated immunity can result in a potentially fatal infection that disseminates outside the lung to the skin and oral mucosa, adrenal glands, bone, spleen, thyroid, gastrointestinal (GI) tract, heart, and central nervous system (CNS).

CLINICAL PRESENTATION AND DIAGNOSIS

Histoplasmosis and coccidioidomycosis frequently present with mild self-limiting, influenza-like or mild lower respiratory tract–like illness 1 to 3 weeks after the inhalation of conidia. The clinical presentation of blastomycosis can range from asymptomatic infection to acute or chronic pneumonia that develops weeks after exposure, to a full-blown disseminated disease.

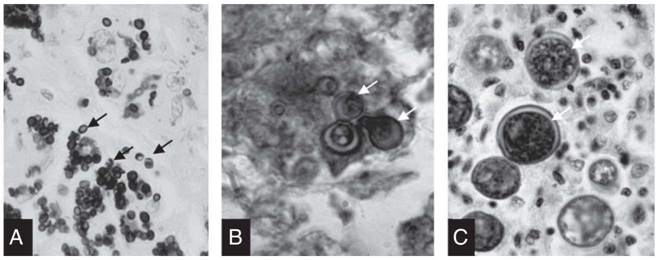

FIGURE 86–2. Histopathology of endemic mycoses in tissue. **A:** Histoplasmosis (yeast). **B:** Blastomycoses (broad-based budding yeast). **C:** Coccidioidomycoses (spherules with endospores).

Severe endemic fungal disease often presents with a clinical history of persistent pneumonia despite multiple courses of antibiotic therapy that is accompanied by fever, chills, cough, arthralgia, night sweats, and weight loss. This clinical presentation is often indistinguishable from other chronic infections such as pulmonary tuberculosis. Therefore, the diagnosis of endemic fungal infection is often prompted by a patient history of prolonged infectious symptoms, travel or residence in an endemic area, and/or participation in activities that result in exposures to soil contaminated by endemic fungi.

Radiological findings

- Chest radiographs often reveal either diffuse or nodular infiltrates in the lung, accompanied by enlargement of the hilar and/or mediastinal lymph nodes.
- Fulminant pneumonia may be seen with high-inoculum exposures, resulting in diffuse lung infiltrates that progress to **acute respiratory distress syndrome** (ARDS) and respiratory failure.

Signs and Symptoms

- Rheumatologic symptoms such as severe arthritis, **pericarditis**, and **erythema nodosum** may be seen in 10% to 30% of patients with endemic fungi.[3-5]
- Dissemination outside the lung is common in patients with suppressed cellular immunity and frequently produces signs of progressing infection.
- Ulcerative oral and cutaneous lesions may also arise with any endemic fungal infection.
- Verrucose (wart-like) skin lesions on sun-exposed areas on the face are particularly suggestive of progressing blastomycosis and frequently mistaken for skin cancer.
- Dissemination of the fungi to bone marrow may result in anemia or thrombocytopenia.
- Hepatomegaly, splenomegaly, and adrenal insufficiency can also occur with the dissemination of the endemic fungi to these internal organs.
- Seizures, meningeal signs, and **hydrocephalus** may occur with the dissemination of the infection to the CNS and signify a poor prognosis.

Definitive diagnosis of an endemic fungal infection requires growth of the fungus from body fluids or tissue, or evidence of cellular or tissue invasion in clinical samples by histopathology. However, cultures may only be positive in the setting of high-inoculum exposures, pneumonia, or disseminated disease. Serologic detection of antibodies is helpful in the diagnosis and management of patients with histoplasmosis or coccidioidomycosis but lacks specificity for the diagnosis of *B. dermatitidis*.[4] In general, a fourfold rise in antibody or complement fixation titers of *Histoplasma* or *Coccidioides*, or any titer greater than 1:16, suggests active infection. However, many clinicians still consider titers as low as 1:8 as evidence of active disease because undetectable titers may be present in one-third of all active infections. Enzyme-linked immunosorbent assays (ELISAs) have been developed for direct detection of *Histoplasma* antigens in serum and urine. Serial antigen testing can also provide a means for assessing response of histoplasmosis to antifungal therapy and detection of relapsing disease.[3]

TREATMENT

KEY CONCEPT The approach to antifungal therapy in patients with endemic fungal infections is determined by the severity of clinical presentation, the patient's underlying immunosuppression, and potential toxicities and drug interactions associated with antifungal treatment. Immunocompetent patients with mild disease following exposure to *H. capsulatum* or *C. immitis* often experience a benign course of infection that does not require antifungal therapy. Persons of Filipino or African descent have a higher risk for dissemination with *C. immitis*, and this may also be taken into consideration for more aggressive treatment.[5] Approximately 9% of patients exposed to coccidioidomycosis (defined by positive IgM or IgG serology) develop pneumonia requiring hospitalization, and 1% may develop infections of the CNS, which are difficult to treat if not incurable.[5]

Current guidelines suggest that patients with mild histoplasmosis or coccidioidomycosis may be initially followed in the outpatient setting with serial antigen or serologic studies to confirm resolving infection. Patients without clinical improvement within the first month can be treated with oral itraconazole for 6 to 12 weeks (Table 86–2).[3,5] Broader spectrum triazoles such as voriconazole and posaconazole, and possibly isavuconazole, appear to have clinically useful activity against endemic fungi but have limited data to recommend their routine first-line use. Fluconazole treatment (6–12 mg/kg/day; 400–800 mg/day) is associated with somewhat higher relapse rates than itraconazole but has fewer GI adverse effects and drug interactions compared to itraconazole. Echinocandins and flucytosine are not clinically useful agents for the treatment of endemic mycoses.

Patients with symptoms persisting longer than 2 weeks, greater than 10% weight loss, extensive pneumonia, or serologic titers greater than 1:8 of histoplasmosis or coccidioidomycosis are candidates for immediate antifungal therapy. Any patient with underlying immunosuppression should also receive immediate antifungal therapy. The following signs and symptoms are

Table 86–2

Common Treatment Regimens for Endemic Fungal Infections

Mycosis	Recommended Treatment Regimens	Comments
Histoplasmosis		
Mild to moderate	Observation or itraconazole 200 mg three times daily for 3 days, then two times daily for 6–12 weeks.	
	Fluconazole 12 mg/kg/day PO for 6–12 weeks adjusted for renal function.[a]	Fluconazole has a higher rate of relapse than itraconazole but is better tolerated by many patients than itraconazole. Echinocandins are not clinically effective against endemic mycoses.
Severe, including CNS disease or immunocompromised host	Amphotericin B 0.7 mg/kg/day IV or liposomal amphotericin B 3–5 mg/kg/day for 12 weeks or until clinically stable.	Liposomal amphotericin B better tolerated than conventional formulations, especially for CNS disease. Patients initially treated with amphotericin B–based regimens are transitioned to itraconazole or fluconazole once they are clinically stable. Corticosteroid therapy should be considered in hypoxic patients with acute pulmonary infection. Itraconazole is less effective for CNS infections.
Blastomycosis		
Mild to moderate	Itraconazole 200 mg three times daily for 3 days, then two times daily for 6–12 months.	
Severe, including CNS disease or immunocompromised host	Amphotericin B 0.7 mg/kg/day or liposomal amphotericin B 3–5 mg/kg/day IV until patient is clinically stable, then itraconazole (non-CNS) or fluconazole 12 mg/kg/day orally adjusted for renal function.[a]	
Coccidioidomycosis		
Mild to moderate, including noncomplicated pneumonia	Observation or itraconazole 200 mg three times daily for 3 days, then two times daily for 3–6 months. OR Fluconazole 6–12 mg/kg/day (400–800 mg daily) daily adjusted for renal function[a] for 3–6 months.	Itraconazole demonstrated trend toward superiority over fluconazole in a randomized controlled trial for progressive, nonmeningeal coccidioidomycosis; however, fluconazole is better tolerated than itraconazole.
Diffuse pneumonia or disseminated infection	Amphotericin B 1–1.5 mg/kg/day with dose and frequency decreased as improvement occurs. Patient then transitioned to triazole therapy. OR Liposomal amphotericin B formulation 3–5 mg/kg/day. Patient then transitioned to triazole therapy.	Fluconazole 800–1000 mg/day adjusted for renal function[a] is often recommended after initial amphotericin B therapy for meningitis.

[a] CrCl > 50–90 mL/min (0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl < 10 mL/min (0.17 mL/s) 50%.

Patient Encounter 1, Part 2: Endemic Fungal Infection

Patient Management

The patient's serum titer for histoplasmosis returns as greater than 1:16. Based on the information presented, select an appropriate treatment plan for the patient's infection.

Should the patient receive antifungal therapy now? What factors need to be considered?

indicators of severe disease that require hospitalization and initial treatment with systemic amphotericin B (see Table 86–2).

- Hypoxia indicated by a partial pressure of oxygen less than 80 mm Hg (10.6 kPa)
- Hypotension (systolic blood pressure < 90 mm Hg)
- Impaired mental status
- Anemia (hemoglobin < 10 g/dL [100 g/L or 6.2 mmol/L])
- Leukopenia (< 1×10^3/mm^3 [1×10^9/L])
- Elevated hepatic transaminases (> 5 times upper limit of normal) or bilirubin (> 2.5 times upper limit of normal)
- Coagulopathy (impaired clotting ability)
- Evidence of dissemination, including cutaneous manifestations
- Meningitis

All patients with blastomycosis require antifungal treatment, even though patients with mild disease can be managed as outpatients with oral itraconazole.[7] Patients with evidence of severe pulmonary disease or dissemination require initial treatment in the hospital with amphotericin B–based regimens until they are clinically stable. Subsequently, they can complete a 6- to 12-month treatment course as outpatients with oral triazoles.[4] Methylprednisolone (0.5–1 mg/kg daily IV) may be administered during the first 1 to 2 weeks of antifungal therapy if the patient develops hypoxemia or significant respiratory distress.

OUTCOME EVALUATION

Response to antifungal therapy may be slow in patients with a prolonged history of infection or severe manifestations. However, gradual improvements in symptoms and reduction in fever are indicators of response to treatment. For histoplasmosis and coccidioidomycosis, decreasing antigen titers or serology are indicative of response to antifungal therapy.[3,5]

Antifungals used for the treatment of endemic mycoses can be associated with many clinically significant drug interactions and toxicities, especially with the prolonged treatment courses required for endemic mycoses. Itraconazole is available as a capsule formulation that should be taken with food and a cyclodextrin-solubilized solution taken without food. The liquid formulation of itraconazole has several advantages over the capsule: it has a better oral bioavailability and does not require the low gastric pH that is required for dissolution and absorption of the capsule. However, the oral solution is somewhat dilute requiring large volume doses, has an unpalatable aftertaste (an issue when taking months of therapy), and has a much higher rate of GI intolerance. Therefore, the capsule formulation is often preferred, provided patients are not on acid suppression therapy (ie, proton pump inhibitors, histamine antagonists, or antacids). Acidic beverages, such as orange or apple juice, or cola can improve the absorption of itraconazole capsules.

Fluconazole is well tolerated and available in both IV and oral formulations that have good bioavailability. Posaconazole is formulated as a micronized suspension that is best absorbed when taken with high-fat meals and in divided doses up to 800 mg/day. A delayed-release tablet formulation of posaconazole with improved bioavailability (permitting substantially lower daily dosages) and fewer gastric pH-associated drug interactions is also available and is the preferred oral treatment formulation of posaconazole in most patients unless the patient cannot swallow the tablet.[8] An IV formulation of posaconazole is also available for patients who cannot take oral formulations. Absorption of voriconazole is not affected by gastric pH but is generally administered 1 hour prior to or 2 hours after eating. Isavuconazole is available in both an IV and oral prodrug formulation that is not affected by gastric pH or food.[9]

Drug interactions are an important concern in patients taking long-term triazole therapy. Itraconazole, voriconazole, and isavuconazole are substrates of the cytochrome P450 (CYP) 3A4 enzyme. Coadministration of itraconazole, voriconazole, and, to a lesser extent, fluconazole, posaconazole, and isavuconazole with inducers of this CYP 3A4 enzyme (eg, rifampin, phenytoin, and phenobarbital) increase drug clearance resulting in ineffective plasma and tissue concentrations of the drug.[10] In general, coadministration of the broader spectrum triazoles (itraconazole, voriconazole, posaconazole, and isavuconazole) with these inducers should be avoided. Itraconazole, voriconazole, posaconazole, and, to a lesser extent, isavuconazole are also potent inhibitors of CYP 3A4, which predisposes these agents to a large number (estimated > 2000) of clinically significant pharmacokinetic drug–drug interactions (such as those with calcineurin inhibitors, chemotherapeutics, antiretrovirals, and statins).[10]

All patients should have their medication profile carefully reviewed prior to initiating and stopping triazole antifungals, preferably with the aid of a computerized drug interaction database. Even in the absence of drug interactions, serum drug levels of triazoles can be unpredictable.[11] Serum drug concentration monitoring or therapeutic drug monitoring (TDM) has been recommended in patients receiving itraconazole, voriconazole, and posaconazole suspension for documented infections, or when inadequate serum concentrations are suspected because of altered absorption or drug interactions.[11] Suspected toxicities, especially CNS adverse effects (such as visual disturbances, dizziness, or hallucinations) during voriconazole therapy,[12] may also be indicative of excessive drug levels that can be detected with TDM (Table 86–3).

All triazole antifungals carry the potential for rash, photosensitivity, and hepatotoxicity. In general, hepatotoxicity is mild and reversible, presenting as asymptomatic increases in liver transaminases, and less frequent increases in total bilirubin. Fulminant hepatic failure is less common and typically mediated by immunologic mechanisms. Therefore, serial monitoring of liver function is recommended in all patients receiving triazole antifungals. Long-term therapy with itraconazole has also been associated with reversible adrenal suppression and cardiomyopathy due to negative inotropic effects of the drug. Long-term therapy with voriconazole can be associated with severe phototoxic reactions and cutaneous erythema in sun-exposed skin, which may not be preventable with sunscreen alone. This phototoxic reaction has been linked to a high risk for developing squamous cell carcinoma or melanoma.[13] Patients should be instructed to avoid sun exposure while on voriconazole therapy and have frequent

Table 86–3

Recommendations for Antifungal Therapeutic Drug Monitoring

Drug	Indication for Monitoring	Time of First Measurement (days)	Target Conc. for Efficacy (mcg/mL or mg/L)	Target Conc. for Safety (mcg/mL or mg/L)
Flucytosine	Routine during the first week of therapy, renal insufficiency, or poor clinical response	3–5	Peak > 20 (155 μmol/L)	Peak < 50 (387 μmol/L) to reduce risk of marrow toxicity
Itraconazole	Routine during first week of therapy, GI dysfunction, suspected drug interactions	4–7	Prophylaxis > 0.5 (0.7 μmol/L); therapy trough > 1–2 (1.4–2.8 μmol/L)	Some evidence to suggest trough > 4 (5.7 μmol/L) increased adverse effects
Voriconazole	Lacking response, GI dysfunction, suspected drug interactions, pediatrics,[a] IV to oral switch, unexplained neurological changes	4–7	Prophylaxis trough > 0.5 (0.7 μmol/L); therapy trough 1–2 (2.9–5.7 μmol/L)	Trough < 6 (17.2 μmol/L) to reduce risk of CNS toxicities
Posaconazole	Lacking response, GI dysfunction, potent acid suppression therapy (ie, proton pump inhibitor), suspected drug interactions	4–7	Prophylaxis trough > 0.5 (0.7 μmol/L); therapy trough 0.5–1.5 (0.7–2.1 μmol/L)	Not established Delayed-release tablet formulation preferred for most patients because of fewer pH drug interactions and improved bioavailability. IV formulation is available for patients who cannot take oral therapy
Isavuconazole	Lacking response, suspected drug interactions, mucormycosis	4–7	Not established, in clinical trials to the average trough concentration surpassed 2 (5.7 μmol/L)	Not established, in clinical trials the average trough concentration surpassed 2 (5.7 μmol/L)

[a] Pediatric patients display accelerated linear clearance of voriconazole. Therefore, higher daily voriconazole dosing (7 mg/kg every 12 hours) is recommended to achieve similar exposures to adults. Some children may require doses as high as 12 mg/kg every 12 hours to achieve similar serum drug exposures to adults. Therefore, therapeutic drug monitoring is recommended.

GI, gastrointestinal; IV, intravenous.

skin examinations by a dermatologist. Long-term voriconazole therapy may also predispose patients to periostitis, or inflammation of tissue surrounding bone due to fluoride toxicity from chronic voriconazole exposure, (fluoride toxicity) that present with nonspecific joint, shoulder, and limb pain that can be diagnosed by X-ray and serum analysis of fluoride levels.[14] Alopecia, chapped lips, brittle nails, and cognitive difficulties have also been reported with longer term voriconazole therapy, especially at higher doses.[15] Peripheral neuropathy may develop in 3% to 17% of patients on long-term triazole therapy and is most frequently reported with itraconazole and voriconazole.[16]

Amphotericin B remains the mainstay of treatment of patients with severe endemic fungal infections. The conventional deoxycholate formulation of the drug can be associated with substantial infusion-related adverse effects (chills, fever, nausea, rigors, and, in rare cases, hypotension, flushing, respiratory difficulty, and arrhythmias). As-needed premedications with low doses of acetaminophen and diphenhydramine, and less frequently nonsteroidal anti-inflammatory agents hydrocortisone or meperidine (if rigors are present), are used to reduce acute infusion-related reactions. Venous irritation associated with the drug can also lead to thrombophlebitis; hence, central venous catheters are the preferred route of administration in patients receiving more than a week of therapy.

The most severe adverse effect associated with amphotericin B therapy is nephrotoxicity, which occurs through direct effects on glomerular filtration (constriction of the afferent arterioles in the kidney tubule) and damage of the distal tubular membrane.[17] Generally, nephrotoxicity with amphotericin B is reversible, provided the drug is stopped. However, treatment interruptions can be problematic in patients with severe infections. Precipitous decreases in glomerular filtration may occur in patients with marked dehydration or during aggressive diuresis. Infusion of normal saline before and after amphotericin B, a practice known as “sodium loading,” can blunt precipitous decreases in renal perfusion pressure and slow the rate of decline in the glomerular filtration rate but may not be tolerated in patients with poor cardiac function. Administration of amphotericin B by continuous infusion reduces the glomerular but not distal tubular toxicity and is generally not advocated because of unproven efficacy. Amphotericin B–associated nephrotoxicity can be delayed by avoiding the use of other drugs with known tubular toxicity such as aminoglycosides, calcineurin inhibitors, cisplatin, or foscarnet. The initial manifestation of tubular toxicity is in patients with severe wasting of potassium and magnesium in the urine. Therefore, patient electrolytes must be carefully monitored, and potassium and magnesium supplementation is always necessary. Hypokalemia and hypomagnesaemia frequently precede decreases in glomerular filtration (increased serum creatinine), especially in patients who are adequately hydrated.[17] Continued tubular damage eventually results in decreases in renal blood flow and glomerular filtration through tubuloglomerular feedback mechanisms that further constrict the afferent arteriole.

During the 1990s, amphotericin B was reformulated into three different lipid-based formulations (Abelcet, AmBisome, and Amphotec) that have reduced rates of nephrotoxicity compared with the conventional deoxycholate formulation (Fungizone). Two of the formulations that are currently available (Abelcet and AmBisome) have lower rates of infusion-related reactions. Although these lipid formulations are generally considered to be as effective as conventional amphotericin B deoxycholate, they are not dosed equivalently to the standard formulation (see Table 86–2).

PROPHYLAXIS

Primary **prophylaxis**, before development of infection, is generally not recommended for endemic fungi. Antifungal prophylaxis is generally recommended in specific situations, including the following:

1. Patients with HIV infection [and with $CD4^+$ cell counts less than 150 cells/mm^3 (150×10^6/L) (histoplasmosis)] living in regions with high endemic case rates (> 10 cases per 100 patient-years), or any patient with positive IgM or IgG antibodies. The recommended regimen is itraconazole 200 mg daily.
2. Secondary prophylaxis or suppressive therapy with itraconazole 200 mg daily is recommended to prevent the recurrence of blastomycosis in immunosuppressed patients if immunosuppression cannot be reversed.[4]
3. In patients with prior CNS disease, fluconazole or voriconazole are preferred over itraconazole and posaconazole due to the lower penetration of itraconazole and posaconazole into the CNS.[5]

OPPORTUNISTIC MYCOSES

KEY CONCEPT Commensal or environmental fungi that are typically harmless can become invasive mycoses when the host immune defenses are impaired. Host immune suppression and risk of opportunistic mycoses can be broadly classified into three categories:

1. A reduction in the number or quality of neutrophils
2. Deficits in **cell-mediated immunity**
3. Disruption of the skin, gut, and/or microbiologic barriers

A reduction in the number of neutrophils (neutropenia) resulting from neoplastic diseases, cytotoxic chemotherapy, marrow transplantation, or bone marrow aplasia is among the most common risk factors for opportunistic mycoses. Functional neutrophil defects may be seen in certain disease states (eg, advanced diabetes mellitus and chronic granulomatous disease) or with high-dose corticosteroid therapy. Deficits in T-cell–mediated immunity associated with HIV infection, high-dose corticosteroid therapy, calcineurin inhibitors, other immunosuppressive drugs, chemotherapy, transplantation, bone marrow failure, and other immunodeficiencies are increasingly prevalent with the prolonged survival of transplant patients or other chronically immunosuppressed populations.

Immune deficits arising from the disruption of the skin GI/genitourinary barriers can also predispose patients to fungal diseases. The most common types of barrier disruptions include surgery or infections/perforations of the abdominal viscus, use of central venous and urinary catheters, parenteral nutrition, and mucositis associated with cytotoxic chemotherapy and antibiotic therapy. Broad-spectrum antibacterial therapy, which is common in high-risk hematology patients and the critically ill patient in the ICU, disrupts the protective microbiologic flora of the gut allowing overgrowth of *Candida* species that can translocate to the bloodstream and invade internal organs.

In general, opportunistic mycoses are difficult to diagnose and are frequently treated empirically before diagnosis is proven. **KEY CONCEPT** Deciding when to initiate antifungal therapy and what opportunistic pathogens to cover is a decision governed largely by the immune deficits of the host, local epidemiology and experience, or clinical or diagnostic clues suggestive of incipient infection.

INVASIVE CANDIDIASIS

EPIDEMIOLOGY AND ETIOLOGY

Candida species are the most common opportunistic fungal pathogens encountered in hospitals, ranking as the third to fourth most common cause of nosocomial bloodstream infections in **ICUs** in the United States and the eighth most common cause of bloodstream infections overall.[18] The incidence of nosocomial candidiasis has increased steadily since the early 1980s, with the widespread use of central venous catheters, broad-spectrum antimicrobials, and other advancements in the supportive care of critically ill patients. In the 1980s, *C. albicans* accounted for more than 80% of all bloodstream yeast isolates cultured from patients. By the late 2000s, this relative frequency of *C. albicans* had decreased to less than 50% in national surveys of bloodstream infections with increasing proportion of infections caused by non-*albicans* species.[19] Because of the inherent resistance (eg, *C. glabrata, C. krusei*, and more recently *C. auris*) of many of the non-*albicans* species, the introduction of fluconazole in the early 1990s is often cited as the key element driving the shift in the microbiology of invasive candidiasis. **KEY CONCEPT** Familiarity with the local epidemiology and frequency of non-albicans *Candida* species in the institution or intensive care unit (ICU) is essential before selecting **empiric** antifungal therapy for invasive candidiasis, as fluconazole is not recommended for the treatment of *C. glabrata* and *C. krusei infections*, and echinocandin resistance among *C. glabrata* is increasing in some centers. *C. auris* is an emerging, multidrug-resistant fungal pathogen for which therapeutic options are limited.

CLINICAL PRESENTATION AND DIAGNOSIS

Invasive candidiasis encompasses several infectious syndromes broadly categorized as candidemia or deep-seated infections, which most frequently affect the kidney, eye, or bones but may also affect heart valves, the CNS, and other organs, including the spleen and liver.[20] A major difficulty in the diagnosis of invasive candidiasis in high-risk patients is distinguishing colonization from true infection. *Candida* frequently colonizes the urine, sputum, and skin and wounds, especially in patients receiving broad-spectrum antibacterial therapy. However, isolation of *Candida* from these sites frequently does not indicate true infection. For example, *Candida* in the urine can be an indication of renal candidiasis or an obstructing fungus ball; however, it must be distinguished from more common benign colonization of the urinary tract, especially in patients with chronic indwelling urinary catheters. Similarly, *Candida* species isolated for respiratory samples (sputum, bronchoalveolar lavage) are nearly always indicative of colonization and not true *Candida* pneumonia, which is a rare clinical entity.

Approximately one-third of all patients with true invasive candidiasis fall within three groups at the time of diagnosis: (a) patients with uncomplicated candidemia in the absence of deep-seated candidiasis, most frequently arising from an infected catheter; (b) candidemia associated with deep-seated candidiasis, most frequently arising from the GI tract or secondary seeding from a separate infection site; and (c) deep-seated candidiasis without candidemia.[21]

Invasive candidiasis is most frequently diagnosed by growth of yeast in blood cultures. Blood cultures successfully detect infection in most patients with candidemia alone, fewer patients with mixed deep-seated disease and intermittent candidemia, and virtually no patients who have infection limited to deep tissues at the time of culture. As a result, it is estimated that half of all episodes of invasive candidiasis are not detected by blood cultures alone. Therefore, a blood culture positive for *Candida* is always considered strong evidence of infection, but a negative blood culture cannot rule out the possibility of invasive candidiasis, especially in patients with multiple underlying risk factors. The development of new diagnostic tools that do not exclusively rely on microbiological isolation of *Candida* has become a major research focus for improving the diagnosis of the infection, especially deep-seated disease.[20]

Serodiagnostic tests have been developed for the detection of *Candida* cell wall antigens, or nucleic acids of *Candida* species, in the hope of improving the detection of invasive disease missed by blood cultures. Currently, the most frequently used test is the Fungitell (1→3)-β-D-glucan test, Associates of Cape Cod, Inc. False-positive results may occur, however, in patients with Gram-negative bacteremia, certain gauze dressing or dialysis membranes, or patients heavily colonized with *Candida* species. Additionally, the presence of other fungal pathogens that produce (1→3)-β-D-glucan as a cell wall component, such as *Aspergillus*, may also lead to a positive Fungitell (1→3)-β-D-glucan test result. More recently the development and Food and Drug Administration (FDA) approval of the T2 Magnetic Resonance–based T2Candida Panel has made possible the rapid, direct, and culture-independent detection of *Candida* species, although this test is not available in all institutions.[22]

Laboratory identification of *Candida* in clinical samples must be performed to the species level whenever possible, as *Candida* species differ considerably in their susceptibility to antifungal agents (Figure 86–3A). Rapid discrimination of *C. albicans* from common non-albicans *Candida* species can be accomplished by the germ tube test, which presumptively identifies *C. albicans* by the early formation (< 4 hours) of a hyphae-like structure when the yeast is incubated in serum at 37°C (98.6°F). Definitive species identification, however, may require an additional 48 to 72 hours after the organism is isolated on agar but can be accelerated with fluorescent in situ hybridization (FISH) of *Candida* species–specific DNA sequences. Matrix-assisted laser desorption/ionization time of flight (MALDI-TOF), polymerase chain reaction (PCR)–based methodologies, and magnetic resonance–based technologies have shown some promise in the early identification of *Candida* species in whole blood specimens in as little as 1 hour, which could shorten the time to earlier diagnosis.

C. albicans remains the most common cause of invasive candidiasis and is the most virulent of *Candida* species but is most susceptible to commonly used antifungals, including fluconazole.[23] Like *C. albicans*, *C. tropicalis* is a relatively virulent species associated with the highest mortality rates but has similar susceptibility profiles as *C. albicans*. *C. parapsilosis* is a less virulent species seen frequently in neonates and adults with central venous catheters. However, many *C. parapsilosis* isolates form thick biofilms on prosthetic materials and catheters that make the organism difficult to eradicate. *C. parapsilosis* is generally susceptible to most antifungals, including fluconazole, although mean inhibitory concentrations (MICs) for echinocandins are higher for other *Candida* species. *C. krusei* is uniformly resistant to fluconazole, although most isolates retain susceptibility to voriconazole and posaconazole. *C. auris* is an emerging highly virulent, multidrug-resistant pathogen that has been associated with infection outbreaks in hospitals and nursing homes.[24] Almost all *C. auris* isolates are resistant to fluconazole, 50% are resistant to voriconazole, 30% are resistant to amphotericin B, and 5% are resistant to echinocandins.[25] Additionally, a major problem with *C. auris* is frequent misidentification by automated systems used by many clinical microbiological laboratories, potentially resulting in the patient getting the wrong treatment. Therefore, specialized methods have been proposed for the detection and identification of *C. auris* in healthcare facilities.[24]

C. glabrata may present as a breakthrough infection on fluconazole prophylaxis and is becoming increasingly resistant to echinocandins.[18] Although *C. glabrata* is generally less virulent than other *C. albicans*, infections with this organism are typically seen

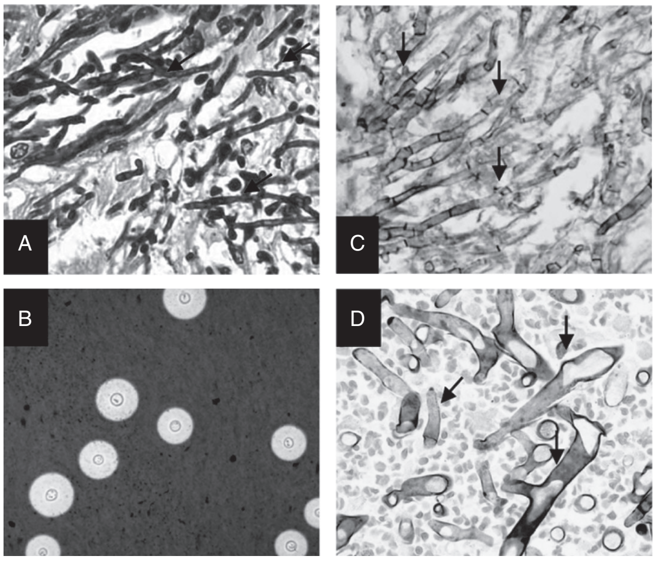

FIGURE 86–3. Opportunistic mycoses in clinical samples. **A:** Candidiasis (tissue). **B:** Cryptococcosis (India ink stain of CSF). **C:** Aspergillosis (tissue). **D:** Mucormycosis (tissue).

Patient Encounter 2, Part 1: Invasive Candidiasis

A 65-year-old man with chronic liver disease is recovering in the ICU after becoming septic secondary to a severe case of spontaneous bacterial peritonitis and develops fever while receiving broad-spectrum antibacterial therapy (meropenem 2 g every 8 hours and vancomycin 1 g every 12 hours). The patient has a central venous catheter and a Foley catheter. Blood cultures are negative at the time, but the patient has yeast growing in the sputum and urine. A serum (1→3)-β-D-glucan test is positive at 80 pg/mL (80 ng/L). Laboratory studies reveal a white blood cell count of 17,500 cells/mm^3 $(17.5 \times 10^9/L)$.

What are this patient's risk factors for developing an invasive fungal infection?

What evidence suggests this patient has an invasive fungal infection despite negative blood cultures?

If antifungal therapy is empirically started in this patient, what information should be considered?

in older patients with poor performance status, and therefore mortality remains high. The marginal dose-dependent susceptibility of *C. glabrata* to fluconazole and increasing echinocandin resistance[26,27] has fueled a growing clinical need for susceptibility testing of this species, as some isolates may demonstrate resistance to multiple antifungal classes. Generally, fluconazole-resistant strains of *C. glabrata* should be assumed to be cross-resistant to other triazoles.

TREATMENT

Seven antifungals (amphotericin B, fluconazole, voriconazole, isavuconazole, caspofungin, micafungin, and anidulafungin) have been studied as monotherapy in prospective, randomized comparative clinical trials for the treatment of invasive candidiasis. In a patient-level meta-analysis of several of these trials, increased patient age, elevated APACHE II score, use of immunosuppressive therapy, and infection with *Candida tropicalis* were independent risk factors for mortality[28] (see Table 86–4). On the other hand, removal of central venous catheters in patients with candidemia and treatment with an echinocandin were variables associated with reduced patient mortality. It is also recommended that all patients with candidemia should undergo an eye examination to rule out *Candida* endophthalmitis, which can be sight threatening if not recognized early and may require direct installation of antifungal therapy for adequate treatment.[21] **KEY CONCEPT** Based on these findings and treatment guidelines endorsed by the Infectious Diseases Society of America, echinocandins are recommended as the preferred initial treatment for invasive bloodstream candidiasis, even in less "critically-ill" patients.[21] Timely initiation of antifungal therapy for invasive candidiasis is critical, as any delay in the initiation of antifungal therapy once a patient has a positive blood culture increases the potential for metastatic seeding of organs and mortality. Clinically stable patients can be transitioned to oral fluconazole or other triazoles once the infecting isolate has been identified and susceptibility is known.[29]

The efficacy of echinocandins for deep-tissue candidiasis is less well established compared to bloodstream infections, and higher failure rates were reported for infections located in anatomical sites where echinocandin penetration is limited (ie, meninges, endophthalmitis, urine).[30] For other forms of deep-tissue candidiasis, triazoles or lipid amphotericin B formulation may be preferable as initial therapy until diagnosis and culture results are available, depending on the suspected organs involved and the clinical severity of illness.[21] Frequently patients are transitioned to oral triazole therapy once stable because of the long-treatment courses that are often required (4–6 weeks minimum) for deep-seated infections.

An important caveat for echinocandin treatment is that cryptococcosis, endemic fungi, or other rare yeast (eg, *Trichosporon* species) occasionally produce fungemia in lymphopenic patients that may initially be mistakenly assumed to be *Candida*. Therefore, initial treatment with a lipid amphotericin B formulation may be judicious in profoundly lymphopenic patients (ie, $CD4^+$ < 250/mm^3 [250 × 10^6/L]) with yeast in blood cultures until fungal identification is confirmed, as echinocandins have poor activity against non-*Candida* yeast.

Echinocandins (ie, caspofungin, micafungin, or anidulafungin), voriconazole, or lipid amphotericin B formulation are often administered as empiric treatment for *Candida* spp. in patients with prolonged neutropenia (ie, absolute neutrophil count < 500 PMN/mm^3 [500 × 10^6/L] for > 7 days) with fever[21] (See Table 86–4). Fluconazole may be an acceptable option in patients expected to have short duration of neutropenia (< 2 weeks) not receiving systemic antifungal prophylaxis with a triazole. Lipid amphotericin B formulations, an echinocandin, or voriconazole are preferred if the patient has or is expected to have prolonged neutropenia (ie, > 2 weeks) because of the increased risk of mold infections. If patients are receiving fluconazole prophylaxis, breakthrough infections with *C. glabrata,* and less frequently *C. krusei*, are possible and should be initially treatable with an echinocandin or amphotericin B.

Urinary candidiasis is a term for group of syndromes that can range from benign colonization (candiduria) in the bladder to invasive disease of the renal parenchyma. Isolation of *Candida* in the urine from nonneutropenic patients does not require antifungal therapy, as transient clearance of *Candida* from the urine has no demonstrable clinical benefit.[21] Patients should receive 7 to 14 days of antifungal therapy for urinary candidiasis if they are (a) symptomatic, (b) have clinical or laboratory evidence of infection, (c) are neutropenic, (d) are low-birth-weight infants; (e) will undergo urologic manipulations, or (f) have renal allografts. Removal of urinary tract instruments, including Foley catheters and stents, is essential to prevent relapse. The preferred therapy is fluconazole 200 mg daily, although IV amphotericin B deoxycholate 0.3 to 1 mg/kg/day is also effective. Other antifungal agents (except for flucytosine) do not achieve appreciable concentrations in the urine and therefore should not be considered first-line treatments for urinary candidiasis.[30] Irrigation with amphotericin B is not effective for infections above the bladder and should not be used in higher risk patients except for its use as a diagnostic tool for confirming a localized infection of the bladder. *Candida* infections of the renal parenchyma secondary to metastatic seeding from the bloodstream are treated in a similar fashion to candidemia.

Oral candidiasis (thrush) is not an invasive disease and can be treated with topical azoles (clotrimazole troches), oral fluconazole, or oral polyenes (such as nystatin or oral amphotericin B). Orally administered and absorbed azoles (fluconazole, voriconazole, or itraconazole solution), amphotericin B suspension, IV echinocandins, or IV amphotericin B are recommended for refractory or recurrent infections.

Although more severe than mucocutaneous candidiasis, esophageal candidiasis typically does not evolve into a life-threatening infection unless the esophagus is ruptured. However, topical

Patient Encounter 2, Part 2: Invasive Candidiasis

The patient was started on caspofungin 50 mg/day following a 70 mg loading dose but 4 days later has persistent fever and develops hypotension. Blood cultures are now growing a germ tube–negative yeast. Laboratory studies revealed a white blood cell count of 16,300/mm^3 (16.3 × 10^9/L), aspartate aminotransferase 147 IU/L (2.44 μkat/L), alanine aminotransferase 72 IU/L (1.2 μkat/L), alkaline phosphatase 303 IU/L (5.05 μkat/L), and normal bilirubin. Serum creatinine is currently stable at 1.2 mg/dL (106 μmol/L).

What factors suggest empiric antifungal therapy should be changed in this patient?

What other procedures should be recommended in this patient to improve management and response to antifungal therapy?

Table 86–4

Therapeutic Approach to Opportunistic Invasive Fungal Infections

Mycoses	Recommended Treatment Regimens	Comments
Candidiasis		
Catheter-related and acute hematogenous	Echinocandin[a] **OR** Fluconazole 12 mg/kg loading dose, then 6–12 mg/kg/day IV every 24 hours (400–800 mg/day) adjusted for renal function[b] **OR** Voriconazole 6 mg/kg every 12 hours IV for 1 day, then 3 mg/kg every 12 hours IV *Second line:* Lipid amphotericin B formulation 3–5 mg/kg /day IV[c] **OR** Amphotericin B 0.7 mg/kg/day IV **OR** Amphotericin B + fluconazole	Treat for 14 days after the last positive blood culture and resolution of signs and symptoms; catheter should be removed whenever possible. Patients can be switched to oral fluconazole when clinically stable if isolate is susceptible. Echinocandins and amphotericin B are preferred agents for fluconazole-resistant species. Voriconazole appears to be effective against fluconazole-resistant *C. krusei*.
Empirical therapy in neutropenic patient	Fluconazole 6–12 mg/kg/day (low risk) adjusted for renal function[b] **OR** Liposomal amphotericin B 3 mg/kg IV every 24 hours **OR** Echinocandin **OR** Amphotericin B 0.7 mg/kg IV every 24 hours	Antifungals with coverage of *Aspergillus* spp. should be used in higher risk patients or prolonged neutropenia (ie, > 2 weeks).
Urinary candidiasis	Fluconazole 200 mg IV or orally for 7–14 days **OR** Amphotericin B 0.3 mg/kg/day IV for 1–7 days	Asymptomatic candiduria does not require therapy.
Cryptococcosis		
Pulmonary Isolated	Fluconazole 6 mg/kg/day IV or PO for 6–12 months adjusted for renal function[b]	
Severe Pulmonary Infection and Meningitis	*Induction:* Amphotericin B 1 mg/kg/day IV + flucytosine 100 mg/kg/day orally divided every 6 hours for 2 weeks adjusted for renal function[c] *Consolidation:* Fluconazole 6–12 mg/kg/day for 10 weeks adjusted for renal function[b] *Second line:* Fluconazole + flucytosine for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[b,c] **OR** Amphotericin + fluconazole for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[b] **OR** Liposomal amphotericin B 5 mg/kg/day IV for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[a]	Therapeutic drug monitoring is required for safe use of flucytosine, see Table 84–3. Echinocandins have no activity against cryptococci. Use of flucytosine–amphotericin B combination therapy was associated with faster CSF sterilization and improved survival. Similar benefits were not observed with combination fluconazole–amphotericin B regimens.
Aspergillosis	Voriconazole 6 mg/kg IV every 12 hours × 2 doses, then 4 mg/kg IV every 12 hours Voriconazole 4 mg/kg oral every 12 hours **OR** Isavuconazole 200 mg (372 mg of isavuconazonium prodrug) every 8 hours for two days, then 200 (372 mg isavuconazonium prodrug) daily ***ALTERNATIVES*** Lipid formulations of amphotericin B **OR** Echinocandin[a] **OR** Posaconazole 300 mg every 12 hours IV day 1, then 300 mg IV daily Posaconazole delayed-release tablet 300 mg twice daily, day 1, then 300 mg daily Posaconazole suspension 200 mg by mouth four times daily for 14 days, then 400 mg PO twice daily **OR** Combination therapy, typically echinocandin plus triazole	Voriconazole can be administered as oral therapy in patients taking oral medications. However, patients with suspected aspergillosis should initially be started on IV therapy. Therapeutic drug monitoring should be considered in patients receiving voriconazole (any formulation) or posaconazole suspension, see Table 84–3. Posaconazole tablets and IV formulations have less pharmacokinetic variability but some patients may still benefit from TDM. Combination therapy with triazole and echinocandin associated with improved survival in patients with galactomannan-diagnosed infection. *A. terreus* and *A. flavus* should be considered resistant to amphotericin B.

[a] Anidulafungin 200 mg loading dose day 1, then 100 mg daily, caspofungin 70 mg loading dose day 1, then 50 mg daily; or micafungin 100 mg daily.

[b] Fluconazole renal dosing adjustments: CrCl > 50–90 mL/min (0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl < 10 mL/min (0.17 mL/s) 50%.

[c] Flucytosine renal dosing adjustments: CrCl > 50–90 mL/min (0.83–1.50 mL/s), 25 mg/kg every 12 hours; CrCl 10–50 mL/min (0.17–0.83 mL/s), 25 mg/kg every 12–24 hours; CrCl < 10 mL/min (0.17 mL/s) 25 mg/kg every 24 hours. Therapeutic drug monitoring is required for safe use of flucytosine (see Table 84–3).

CSF, cerebrospinal fluid; IV, intravenous; PO, oral; TDM, therapeutic drug monitoring.

therapy is ineffective. Triazole antifungals (fluconazole, itraconazole solution, or voriconazole), echinocandins, or IV amphotericin B (in cases of unresponsive infections because of antifungal resistance, most commonly to fluconazole) are effective treatment options. Parenteral therapy should be used in patients who are unable to take oral medications.

OUTCOME EVALUATION

The outcome of invasive candidiasis is influenced by the timely administration of appropriately dosed antifungal therapy appropriate for the *Candida* species isolated, as well as early source control (eg, removal of infected catheters) that reduces the risk of progression to sepsis. To ensure appropriate and cost-effective use of diagnostics and treatments for invasive candidiasis, some institutions have devised "*Candida* treatment bundles" to ensure logical evidence-based interventions in the management of invasive candidiasis and support antifungal stewardship. Examples of elements of treatment bundles for invasive candidiasis are highlighted at the end of the chapter (see Patient Care Process section).

PROPHYLAXIS

Prophylaxis for invasive candida infections has been evaluated in high-risk populations such as those with neutropenia, hematopoietic stem cell transplant, or nonneutropenic patients requiring hospitalization in an intensive care unit. Fluconazole (400 mg/day) has been studied as a prophylactic regimen to prevent invasive candidiasis in patients with prolonged (> 2 weeks) neutropenia.[21] Placebo-controlled, prospective randomized trials performed in the 1990s demonstrated that fluconazole was effective in reducing the frequency, morbidity, and, in some trials, mortality due to invasive candidiasis in neutropenic patients if administered until marrow recovery. However, the major limitation with fluconazole is its lack of mold coverage needed for high-risk patients with prolonged (ie, > 3 weeks) neutropenia. Itraconazole, voriconazole, posaconazole, and the echinocandin micafungin have demonstrated a benefit in reducing the incidence of invasive candidiasis when used for prophylaxis in hematopoietic cell transplant recipients until engraftment; however, all of the drugs have limitations with respect to prolonged administration in high-risk patients. Therefore, the approach toward antifungal prophylaxis is often institution-specific depending on the patient population, epidemiology of invasive fungal infections, and options for outpatient IV drug therapy.

Use of antifungal prophylaxis for invasive candidiasis in nonneutropenic patients remains an area of controversy. Fluconazole prophylaxis has been shown to reduce the incidence but not necessarily mortality associated with invasive candidiasis in select high-risk transplant populations (eg, liver, pancreatic, or small-bowel transplantation) or subsets of ICU patients at high risk of infection (ie, neonatal intensive care).[21] Because prophylaxis can result in excessive antifungal use in lower risk patients, many experts have advocated **preemptive** (ie, starting therapy based on biomarkers of infection such as serum β-glucan) or empirical (symptoms of infection) treatment approaches in this population instead of routine prophylaxis.

A multiinstitutional prospective randomized trial of administering empirical fluconazole (800 mg/day versus placebo) in ICU patients with persistent fever failed to demonstrate significant benefits in reducing the incidence or mortality associated with invasive candidiasis.[31] Similarly, recent multiinstitutional studies that focused on ICU patients identified as "high risk" for invasive candidiasis that administered either caspofungin[32] or micafungin[33] failed to demonstrate any mortality benefit. Therefore, many questions persist regarding the optimal approach for preventing or preemptive treating invasive candidiasis in nonneutropenic ICU patients.

CRYPTOCOCCOSIS

EPIDEMIOLOGY

Cryptococcus neoformans is an encapsulated yeast that can infect normal hosts but has historically been associated with severe infections in immunocompromised patients. *C. neoformans* is divided into two varieties based on serotype: *C. neoformans* var. *neoformans* (serotypes a and d) that is associated with infections in immunocompromised patients, and *C. neoformans* var. *gattii* (serotypes b and c) that is associated with infections in healthy hosts. *C. neoformans* var. *gattii* is found predominantly in tropical and subtropical climates with eucalyptus trees and has been linked to infectious outbreaks around Vancouver Island and the US Pacific Northwest. *C. neoformans* var. *neoformans* is found worldwide and is associated with pigeon droppings and other avian excreta. Before the AIDS pandemic, cryptococcosis was a relatively uncommon disease but became a leading cause of meningitis among HIV-infected patients. Although the incidence of cryptococcal meningitis has declined in developed countries with the widespread use of highly active antiretroviral therapy (HAART), *C. neoformans* remains an important pathogen in the developing regions with high rates of AIDS and in immunocompromised patients, including transplant and cancer patients, who may present with initially indolent pulmonary forms of the infection.

CLINICAL PRESENTATION AND DIAGNOSIS

C. neoformans is acquired primarily through inhalation of the desiccated yeast particles found in the environment. Inhaled cells reach distal alveolar spaces where they gradually rehydrate and form a polysaccharide capsule that is resistant to phagocytosis. Defects in cellular immunity allow reconstitution of the protective capsule and multiplication of yeast in the lungs. Although alveolar macrophages phagocytose the yeast, containment and killing require a coordinated response between innate and adaptive humoral (complement and anticryptococcal antibodies) and T-cell–mediated host responses.[6] Deficiencies in host cell–mediated immunity allow the yeast to survive as a **facultative** intracellular pathogen in macrophages as they migrate from the lung to draining lymph nodes, leading to dissemination via the bloodstream to the meninges.

Unlike most opportunistic fungi, true virulence factors have been identified for *C. neoformans*. The capsules, including the soluble polysaccharides released from the yeast cells during infection, impair phagocytosis and binding of anticryptococcal antibodies. Primary cryptococcal infection begins in the lung, presenting as a mildly symptomatic or asymptomatic infection that resolves spontaneously or undergoes encapsulation in noncalcified lung nodules. These isolated nodules may be detected on chest X-rays during routine workup and aspirated or removed because of concerns for lung cancer.

In the immunocompromised host, infection of the lung may present with more diffuse, bilateral, and interstitial disease that mimics the presentation of *P. jiroveci (carinii)* pneumonia (PCP). Dissemination to other organs, particularly the CNS, eye, and possibly the skin, is more likely to occur in patients with severe deficits in cell-mediated immunity. Fever, cough, dyspnea, and pleural pain are common at presentation, with accompanying hypoxemia that can rapidly evolve to acute respiratory failure.

Because the features of diffuse pulmonary cryptococcosis overlap with other opportunistic pathogens, early diagnosis requires bronchoalveolar lavage or transbronchial biopsy, which can effectively diagnose 80% to 100% of cases.[34] The clinical course of diffuse cryptococcal pneumonia can be as severe as PCP, with mortality rates approaching 100% in untreated patients by 48 hours.

C. neoformans readily disseminates from the lung to the CNS, specifically the leptomeninges, and occasionally the parenchyma of the brain. The clinical characteristics of cryptococcal meningitis differ somewhat, however, between patients with and without underlying AIDS. In patients without AIDS, disease presentation is more insidious, and symptoms such as dizziness, irritability, decreased comprehension, and unstable gait may present many weeks to months before the diagnosis is established. Patients with AIDS generally present much later in the course of disease with severe meningoencephalitis.[34] The most common signs and symptoms on presentation are fever, headache, **meningismus**, photophobia, mental status changes, and seizures. CT or more tissue-sensitive imaging techniques such as magnetic resonance imaging (MRI) may reveal cerebral edema, multiple areas of enhanced nodules, or a single mass lesion (cryptococcoma). Examination of the cerebrospinal fluid (CSF) often reveals increased opening pressure upon lumbar puncture, but glucose, protein, and leukocyte levels can be normal.[34]

LABORATORY DIAGNOSIS

Clinical diagnosis is confirmed by cultures from the blood, CSF, or other clinically relevant fluids or tissue. *C. neoformans* can be directly visualized in the CSF when stained with India Ink, which is excluded by the yeast capsule (Figure 86–3B). However, infection is most frequently diagnosed by the detection of cryptococcal antigen in either serum or CSF, which has high sensitivity and specificity (> 95%) and correlates with fungal burden.[34] A positive serum antigen test of greater than 1:4 strongly suggests cryptococcal infection, and greater than or equal to 1:8 is indicative of active disease. Antigen titers in serum are positive in 99% of patients with cryptococcal meningitis and often exceed 1:2048 in patients with AIDS.[34] However, the time course of cryptococcal antigen elimination is unknown, and a positive test result can persist for many years. Changes in the CSF cryptococcal antigen titers have limited value in the monitoring of drug therapy for cryptococcal meningitis, although it is expected that a decrease should be seen after 2 or more weeks of antifungal therapy.[34]

TREATMENT

Cryptococcal meningitis is fatal if left untreated. Because pneumonia frequently precedes dissemination of disease and subsequent meningitis, all patients with culture-, histopathology-, or serology-proven disease should receive antifungal therapy. In patients with isolated pulmonary cryptococcosis, fluconazole is generally considered to be the therapy of choice (see Table 86–2).[34] Alternatively, itraconazole, voriconazole, or combination therapy (fluconazole plus flucytosine) has also been used with some success, but these regimens are generally considered inferior to amphotericin B and are recommended only for persons unable to tolerate or unresponsive to standard treatment. Echinocandins do not have activity against *C. neoformans*.

Disseminated or CNS cryptococcosis requires a more aggressive treatment approach. Pretreatment predictors of a poor prognosis include the following:

- Progressive underlying disease or immune dysfunction
- Abnormal mental status at the time of presentation
- Increased opening pressure on lumbar puncture (> 260 mm H_2O [2.55 kPa])
- High fungal burden as reflected by a CSF antigen titer (in AIDS patients) of greater than 1:2048

Clinical trials performed by the National Institute of Allergy and Infectious Diseases (NIAID) and Mycoses Study Group have defined the standard treatment regimen for cryptococcal meningitis consisting of 2 weeks of induction antifungal therapy with combination amphotericin B (0.7 mg/kg/day) plus flucytosine (100 mg/kg/day) for cryptococcal meningitis, followed by consolidation therapy with fluconazole (400 mg daily) for 8 weeks (see Table 86–2).[34] However, other combinations of either fluconazole plus flucytosine or fluconazole plus amphotericin B were sometimes recommended due to difficulties in obtaining flucytosine (especially in developing countries) due to both the high cost of the medication and toxicity (such as myelosuppression, hepatic dysfunction, renal dysfunction, and cardiac toxicity) (see Table 86–2).

KEY CONCEPT In a landmark study addressing which combination is best for cryptococcal meningitis, significantly fewer deaths were observed in patients receiving amphotericin B plus flucytosine compared to patients receiving amphotericin B alone, or a combination of amphotericin B plus fluconazole.[35] Notably, the amphotericin B–flucytosine combination was associated with more rapid clearance of yeast from the CSF versus other regimens.

PROPHYLAXIS

Fluconazole (200 mg/day) is recommended as maintenance therapy for life in patients with persistent underlying immune dysfunction to prevent recurrent cryptococcal meningitis.[34] Available data suggest it is safe to discontinue maintenance therapy in AIDS patients who have had a sustained immunologic response on effective antiretroviral therapy (ie, $CD4^+$ count greater than 100 cells/microliter [100×10^6/L] with undetectable or very low viral RNA) if they have received at least 12 months of antifungal therapy.[34] Occasionally, initiation of HAART can result in the reactivation of a subclinical, immunologic manifestation of cryptococcal infection (or other opportunistic infections). Manifestations of this **immune reconstitution inflammatory syndrome (IRIS)** may include exacerbations of meningitis or necrotizing pneumonia. Antifungal therapy plus a nonsteroidal anti-inflammatory agent or prednisone has been used successfully in patients with cryptococcal-associated IRIS.[36] However, there are few studies that have evaluated treatment options for the control of IRIS. To avoid this potential complication, initiation of HAART is typically delayed by 2 to 10 weeks.

INVASIVE ASPERGILLOSIS

EPIDEMIOLOGY

KEY CONCEPT Invasive mold infections, most frequently due to *Aspergillus* species but occasionally caused by *Fusarium* spp. or Mucorales, may cause infection in patients undergoing intensive cancer chemotherapy required for hematologic malignancies, and prolonged immunosuppression following hematopoietic and solid organ transplantation.[37] The four most common *Aspergillus* species that cause invasive infection in humans are *Aspergillus fumigatus*, *Aspergillus flavus*, *Aspergillus terreus*, and *Aspergillus niger*. Of these four species, *A. fumigatus* accounts for most infections. However, identification of *Aspergillus* mold in culture to the species level when cultures are available is still important because *Aspergillus terreus* and *Aspergillus flavus* display relatively higher MICs

(resistance) to amphotericin B. Additionally, less common mold infections such as fusariosis and mucormycosis often present with similar clinical and radiographic features as aspergillosis but require different treatment approaches due to their inherent resistance to many antifungal agents. Early and accurate diagnosis of IA improves the outcome of infection, reducing mortality rates by 30% to 50% with the timely administration of effective antifungal therapy.[37]

CLINICAL PRESENTATION AND DIAGNOSIS

The pathogenesis of IA is defined largely by the underlying immune dysfunction of the host. The most common route of acquisition for *Aspergillus* is through the respiratory tract. Conidia dispersed in air currents are continuously inhaled through the sinuses and mouth and penetrate down to distal alveolar spaces (see Figure 86–4). Most conidia are rapidly phagocytosed and removed by resident macrophages and neutrophils in the upper and lower respiratory tract.[6] However, macrophage function may be suppressed following transplantation, cytotoxic chemotherapy, or in patients who have received high-dose corticosteroid therapy. Conidia that escape phagocytosis begin to germinate into hyphal forms that invade blood vessels or contiguous tissues or bone (in sinuses), resulting in hemorrhage and/or infarction and coagulative necrosis. Once in the bloodstream, viable hyphal fragments can break off and disseminate to distal organs, including the brain. Control of the infection at this stage requires development of an adaptive T-helper cell type 1 (TH1) or type 17 (TH17) response to enhance the fungicidal activity of neutrophils against hyphal elements.[6] Patients with dysregulated, suppressed T-cell–mediated immunity, or prolonged neutropenia are unable to control fungal growth and are at high risk for dissemination of the infection to other organs, including the brain. Without early diagnosis and antifungal therapy, IA in persistently immunosuppressed patients is uniformly fatal.

Signs and symptoms of IA are often subtle in the immunocompromised host. Fever is common but nonspecific for infection and may be accompanied by pleuritic chest pain, cough, hemoptysis, and/or friction rub.[37] Neurologic signs, including seizures, hemiparesis, and stupor, may be present in patients with dissemination to the brain. Cutaneous plaques or papules characterized by a central necrotic ulcer or eschar occur in up to 10% of patients with disseminated disease; however, concomitant blood cultures are often negative. Chest radiographs cannot detect early forms of disease and may remain negative in up to 10% of patients within 1 week of death. Nodular lesions detected by high-resolution computed tomography (HRCT), along with fever, are often the first indication of invasive pulmonary aspergillosis in severely immunocompromised patients. CT images of the lung often reveal wedge-shaped or nodular lesions, surrounded by intermediate attenuation called the "halo sign" (Figure 86–5). These early lesions on CT scans represent hemorrhage and

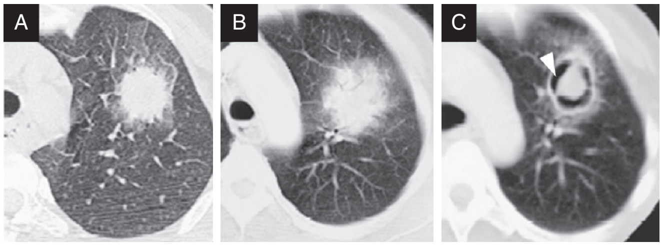

FIGURE 86–5. Radiographic evolution of invasive pulmonary aspergillosis in a neutropenic patient. **A:** Early halo sign of ground glass opacity surrounding nodular lesions. **B:** Nonspecific infiltrate of increased diameter. **C:** Air-crescent sign observed with neutrophil recovery, cavitation of infected lung in walled off cavity with air (*arrowhead*).

Patient Encounter 3: Invasive Aspergillosis

A 37-year-old woman with acute myeloid leukemia who received autologous hematopoietic stem cell transplantation presents to the clinic 36 days after transplant with complaints of fever. On laboratory examination, she is noted to have an alanine aminotransferase of 153 IU/L (2.54 μkat/L), aspartate aminotransferase 127 IU/L (2.11 μkat/L), and total bilirubin of 1.8 mg/dL (31 μmol/L). The patient has an absolute neutrophil count of 770 (770×10^6/L). Her current medications include tacrolimus 5 mg twice daily (most recent level: 15 ng/mL [15 mcg/L; 18.3 nmol/L]), prednisone 10 mg daily, levofloxacin 500 mg daily, fluconazole 200 mg/day, and valacyclovir 500 mg twice daily. A CT scan of the chest reveals a single dense pleural-based lung nodule in the left lung. A serum galactomannan test is reported to be positive (index 0.8, positive when > 0.5). The primary service wishes to start isavuconazole.

What are the patient's risk factors and signs that suggest she has an invasive fungal infection?

What potential advantages are there to choosing isavuconazole as opposed to voriconazole?

If the patient's infection appears to resolve and he continues to take isavuconazole for months while tapering immunosuppression, what are some of the toxicities potentially associated with prolonged isavuconazole therapy?

edema surrounding an infarcted blood vessel. Despite "effective" antifungal therapy, lesions on CT scan may continue to increase in size in neutropenic patients until neutrophil counts recover, at which time they begin to cavitate, forming the "air-crescent sign" on chest radiographs, indicative of resolving infection. Immunocompromised patients on fluconazole with progressive sinus or pulmonary disease by radiography should be considered to have a possible mold infection and receive antifungal therapy directed (at minimum) against *Aspergillus* species.

LABORATORY DIAGNOSIS

Like other invasive mycoses, definitive diagnosis of aspergillosis requires histopathologic evidence of hyphal invasion in tissue (see Figure 86–3C and D). However, procedures needed to establish a definitive diagnosis by sampling of suspicious lesions (eg, fine needle aspiration or open-lung thoracoscopic biopsy) are not feasible in many patients with underlying thrombocytopenia secondary to hematologic malignancies or chemotherapy. Even if **hyphae** are observed in tissue, histopathology alone cannot distinguish *Aspergillus* from other angioinvasive septate molds, such as *Fusarium*, which have different patterns of antifungal susceptibility (see Table 86–1). Therefore, respiratory and/or wound cultures (if cutaneous or sinus/hard palate lesions are present) are important factors in the modification of empiric antifungal therapy.

Respiratory cultures, including sputum, bronchial washings, or bronchoalveolar lavage, have a low sensitivity for diagnosis of IA but a higher positive predictive value in severely immunocompromised patients. Therefore, a negative bronchoalveolar lavage culture does not rule out invasive pulmonary aspergillosis, but a positive culture in a high-risk patient (eg, allogeneic hematopoietic cell transplant patients) indicates pulmonary aspergillosis in at least 60% to 80% of such patients. Blood cultures have little diagnostic value for IA but may reflect true disease with *A. terreus*. Patients with limited lung involvement or on prophylactic or empiric antifungal therapy may continue to be culture negative for *Aspergillus* species, despite the appearance of progressing disease. Therefore, negative cultures are never the sole indication for stopping antifungal therapy in patients with suspected or proven aspergillosis.

Considerable effort has been focused in the last decade to develop non–culture-based laboratory methods (antigen detection, PCR) for the diagnosis of IA. The hope is that these surrogate tests could detect early evidence of *Aspergillus* infection before significant target organ damage eventually detected by CT scans occurs. Currently, most centers use an ELISA-based assay for the detection of a polysaccharide component of the *Aspergillus* cell wall called galactomannan. Although several large prospective studies have found that the sensitivity and specificity of the assay approaches 90% in neutropenic patients with hematologic malignancies, the median time span between galactomannan detection and clinical signs and symptoms of IA averages less than 6 days. The sensitivity of the galactomannan may be enhanced if the test is performed on bronchial lavage fluid collected during bronchoscopy. Other factors such as patient immune status (higher sensitivity in neutropenic versus nonneutropenic patients) antibacterial therapy, antifungal prophylaxis, and diet may affect the sensitivity and specificity of the galactomannan test.[37] For example, false-positive results are reported more frequently in pediatrics, following the ingestion of certain cereals, pastas, nutritional supplements, or soy sauce. Piperacillin–tazobactam therapy was also associated with false-positive galactomannan tests in the past, but more recent studies have suggested that galactomannan contamination of the antibiotic is now uncommon.[39]

Increasing galactomannan levels are a harbinger of breakthrough infection, and declining galactomannan concentrations are an early indicator of response to treatment. However, antifungal therapy is rarely stopped in patients once the serum galactomannan becomes negative, especially in persistently immunosuppressed patients. Hence, the galactomannan test and other non–culture-based strategies, such as serum β-glucan, which can also be detected during *Aspergillus* infection, serve as complementary methods to confirm results from microbiologic, histopathologic, and radiographic investigations directed toward diagnosing IA.[40]

In the past, antifungal susceptibility testing was not routinely recommended for *Aspergillus* spp. in treatment guidelines because of limited data to support the recommendation. *Aspergillus terreus* and *A. flavus* were the major concerns because of their intrinsic resistance to amphotericin B. However, more recently multi-triazole-resistant *Aspergillus fumigatus* spp. have been reported in China, Canada, the United States, and several European countries, with especially high levels in the Netherlands and the United Kingdom.[38] These trends suggest that MIC testing (when isolates can be grown from patient) may be increasingly necessary to confirm susceptibility to first-line antifungal treatments.

TREATMENT

Four comparative randomized controlled clinical trials have evaluated antifungal therapies for the treatment of diagnosis-proven IA. Voriconazole or isavuconazole are considered in consensus treatment guidelines to be the first-line antifungal for IA (see Table 86–2), as voriconazole has been shown to be associated with improved patient survival as compared to amphotericin B.[36] However, patients who are intolerant to triazoles, have ongoing hepatotoxicity issues, or have received voriconazole or posaconazole prophylaxis in the recent past may initially be treated with a liposomal amphotericin B formulation. Lipid amphotericin B formulations are recommended over echinocandins because of their better coverage of Mucorales molds, which sometimes break through on *Aspergillus*-active therapy because of their intrinsically higher resistance to voriconazole and other antifungals. Echinocandins are not typically recommended as a frontline monotherapy regimen for invasive aspergillosis due to poorer responses rates in nonrandomized trials compared to triazoles.[41] Once the infection has stabilized and diagnosis is clarified, patients can be transitioned back to an intravenous or oral triazole for the completion of therapy.

Isavuconazole is a newer triazole unique from other agents because it is administered as a prodrug, isavuconazonium, which is rapidly cleaved in vivo to the active drug (isavuconazole) and an inactive prodrug cleavage product (BAL8728). In a phase 3 trial, patients with proven or probable aspergillosis treated with isavuconazole achieved similar clinical response rates as a standard voriconazole regimen, but with significantly fewer hepatic, skin, and visual adverse effects.[9] Isavuconazole has also been reported to be as effective as amphotericin B–based treatment for mucormycosis. Therefore, isavuconazole appears to be a promising alternative to voriconazole for the treatment of IA.

Multiple studies in vitro and in animal models, as well as small clinical studies, have suggested that administration of an echinocandin with a triazole such as voriconazole may be synergistic and improve survival in IA over monotherapy, but prospective clinical studies, until recently, have been lacking. A multicenter, randomized clinical trial comparing voriconazole–anidulafungin combination therapy to voriconazole monotherapy for proven or probable aspergillosis reported a trend in improved 6-week survival for patients randomized to combination therapy, that was significant among a post hoc analyzed group of patients whose disease was diagnosed with galactomannan antigen but not culture (reflecting patients with earlier diagnosed disease).[39] Nevertheless, the failure of the study to meet its primary endpoint objective raises lingering questions about the efficacy of combination therapy, and many clinicians reserve the use of combination regimens for patients with extensive disease (ie, multifocal or bilateral pneumonia, disseminated infection) or in cases of suspected breakthrough infection.

PROPHYLAXIS

Primary antifungal prophylaxis against *Aspergillus* is recommended in guidelines for some groups of patients with baseline risk of IA that approaches or exceeds 10%. These subgroups typically include patients with acute myeloid leukemia undergoing remission induction chemotherapy, or allogeneic hematopoietic stem cell transplants with graft-versus-host disease. Depending on the institution and local epidemiology, other groups of patients may also be considered candidates for prophylaxis. **KEY CONCEPT** Posaconazole was shown in two prospective randomized trials to reduce Aspergillus-associated death in patients with acute high-risk leukemia and reduce mold infections in patients with graft-versus-host disease following hematopoietic stem cell transplantation. Similar data are available for voriconazole, HSCT, but no significant advantage was observed compared to standard fluconazole prophylaxis plus intensive galactomannan monitoring in the hematopoietic stem cell transplant patients.[42]

Patient Care Process

Collect Information:

- Review the medical history, physical assessment findings, and recent laboratory results of the patient to assess current immunological status and organ function.
- Perform a medication history for use of prescription and nonprescription medications. Identify allergies to medications and other substances.

Assess the Information:

- Analyze patient's medication profile for potential drug interactions with triazole antifungals using an updated computerized drug interaction database.
- Confirm prescribed antifungal therapy is the appropriate spectrum for likely fungal pathogen(s).
- Review whether modifiable risk factors affecting treatment outcome (eg, timely administration of antifungal therapy, catheter removal in patients with invasive candidiasis) have been addressed.
- Ensure prescribed antifungal dose is appropriate for patient age, weight, renal, and/or hepatic function.

Develop a Care Plan:

- Confirm prescribed antifungal therapy is the appropriate spectrum for likely fungal pathogen(s).
- Ensure prescribed antifungal dose is appropriate for patient age, weight, renal, and/or hepatic function.
- Prepare a strategy for therapeutic drug monitoring (TDM) for antifungals with unpredictable pharmacokinetics (eg, itraconazole, voriconazole, and posaconazole suspension).
- Anticipate how antifungal therapy can be modified when culture results become available, intolerance to the drug of first choice, or if there is consideration of switching from IV to oral therapy.

Implement the Care Plan:

- Educate the patient about potential for medication adverse effects, importance of taking medications correctly, and potential for drug interactions.
- Review TDM results, microbiology and susceptibility information if available, and treatment response parameters to ensure patient is on correct antifungal at the best dose.
- Streamline antifungal therapy if possible and/or switch to oral therapy if patient is clinically stable.

Follow-up: Monitor and Evaluate:

- Monitor patient clinical, laboratory, and radiographic parameters to assess effectiveness and safety of therapy.
- Reevaluate potential for serious drug interactions.
- Consider TDM if patient has changes to medication profile, change in clinical status, or new-onset toxicity.

OUTCOME EVALUATION

Response to antifungal therapy in invasive molds is slow and difficult to judge by clinical signs alone. Resolution of fever and eventual clearing of CT scans (in the case of lung infections) are indications of response to antifungal therapy. Toxicity associated with antifungal therapy is similar in these patients as in those described earlier. Patients who develop breakthrough infections on voriconazole should also undergo a careful clinical workup for other invasive mold pathogens such as mucormycosis (see Table 86–1), which are not susceptible to voriconazole. In most cases, antifungal therapy may be continued until immunosuppression has resolved.

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
ARDS	Acute respiratory distress syndrome
CNS	Central nervous system
CrCl	Estimated creatinine clearance
CSF	Cerebrospinal fluid
CT	Computed tomography
CYP	Cytochrome P450 isoenzyme
ELISA	Enzyme-linked immunosorbent assay
FISH	Fluorescent in situ hybridization
HAART	Highly active antiretroviral therapy
HRCT	High-resolution computed tomography
IA	Invasive aspergillosis
ICU	Intensive care unit
IRIS	Immune reconstitution inflammatory syndrome
IV	Intravenous
MALDI-TOF	Matrix-assisted laser desorption/ionization time of flight
MIC	Minimum inhibitory concentration
NIAID	National Institute of Allergy and Infectious Diseases
PCP	*Pneumocystis jiroveci (carinii)* pneumonia
PCR	Polymerase chain reaction
PMN	Polymorphonuclear cell
TDM	Therapeutic drug monitoring

Human Immunodeficiency Virus Infection

Mary F. Banoub, Jennifer L. Bailey,
and Fidelia Bernice

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the routes of transmission for human immunodeficiency virus (HIV) and its natural disease progression.
2. Identify typical and atypical signs and symptoms of acute and chronic HIV infection.
3. Identify the desired therapeutic outcomes for patients living with HIV.
4. Recommend appropriate first-line pharmacotherapy interventions for patients with HIV infection.
5. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for HIV infection.
6. Educate patients about the disease state, appropriate lifestyle modifications, and drug therapy required for effective treatment.

INTRODUCTION

Human immunodeficiency virus (HIV) is the virus that causes acquired immunodeficiency syndrome (AIDS). HIV primarily targets CD4$^+$ T-lymphocytes, which are critical to proper immune system function. If left untreated, most patients experience a prolonged asymptomatic period followed by rapid, progressive immunodeficiency. AIDS is defined by a CD4$^+$ cell count below 200 cells/mm^3 (200 × 10^6/L), a CD4$^+$ cell percentage of total lymphocytes less than 14% (0.14), or the presence of one of the Centers for Disease Control and Prevention (CDC) AIDS-defining conditions, such as pneumocystis pneumonia, and Kaposi sarcoma, and HIV-related encephalopathy.[1]

Fortunately, significant progress in research and drug development over the past several decades has drastically improved both the length and quality of life of persons living with HIV (PLWHIV), transforming HIV into a chronic, manageable disease state. Current efforts can now focus on care connection and retention, long-acting therapies and regimen simplification strategies, and novel prevention strategies.

EPIDEMIOLOGY

As of 2019, approximately 38 million people globally are living with HIV, of which 1.7 million were newly infected and an estimated 7.1 million unaware of their infection. Approximately 70% of these cases are in sub-Saharan Africa and globally, women and girls accounted for 48% of all new HIV infections in 2019. In 2019, approximately 690,000 people worldwide died from AIDS-related illnesses, which is a 39% decrease since 2010.[2]

In the United States, at the end of 2018, an estimated 1 million adults and adolescents (persons aged 13 years and older) were living with diagnosed HIV infection. From 2014 to 2018, the number of diagnoses among male and female adults and adolescents decreased, while diagnoses for transgender male-to-female and transgender female-to-male increased. The highest rate of diagnoses per age-group was in those aged 25 to 29 years; the highest rate by race/ethnicity was in Blacks and African Americans. Male-to-male sexual contact accounted for the highest percentage of diagnoses by transmission category.[3]

ETIOLOGY, TRANSMISSION, AND PATHOPHYSIOLOGY

Etiology

HIV is a retrovirus and member of the genus *Lentivirus*. Human infection is believed to have originated from a type of chimpanzee in Central Africa. There are two molecularly and serologically distinct but related types of HIV: HIV-1 and HIV-2. HIV-1 is the most widespread, whereas HIV-2 is found predominantly in West Africa. This distinction is important as certain antiretrovirals cannot be used to treat HIV-2.

Transmission

HIV is primarily transmitted by sexual contact, by contact with blood or blood products, and from mother to child during gestation, delivery, or breastfeeding. Specifically, HIV is transmitted through certain body fluids—blood, semen, preseminal fluid, rectal fluids, vaginal fluids, and breast milk—which requires contact with a mucous membrane, damaged tissue, or be directly injected into the bloodstream. The risk of acquiring HIV varies depending on the type and frequency of exposure or behavior, such as injection drug use (needle or equipment sharing), unprotected sexual intercourse with high-risk individuals, and the presence of other sexually transmitted infections (STIs) (eg, *chlamydia*, *gonorrhea, and syphilis*).

The most common method for transmission of HIV is receptive anal and vaginal intercourse, with the highest probability of transmission being with receptive anal intercourse (138 infections per 10,000 exposures).[4] Parenteral transmission of HIV primarily occurs through injection drug use by sharing contaminated needles or injection-related supplies and accounts for about 1 in 15 diagnoses in the United States.[3] Less than 1% of all cases of HIV infection occur as a result of transfusions of contaminated blood,

blood products, or infected transplant organs.[3] Occupational HIV transmission is extremely rare, with the average risk of infection after a needle stick of cut exposure estimated at 0.23%.[5] Across all of the aforementioned modes, the probability of transmission increases when the infected partner (or source) has a high level of viral replication and subsequent high viral load. Transmission risk is also heightened when the uninfected partner has ulcerative disease, compromised mucosal surfaces, or (in men) has not been circumcised.

Perinatal infection (also known as vertical transmission or mother-to-child transmission [MTCT]) can occur during gestation, at or near delivery, and during breastfeeding. In the absence of specific interventions, the risk of MTCT up to and including delivery ranges from 15% to 30%. Breastfeeding can further increase the risk by 5% to 15%.[6] Risk increases significantly with increasing maternal viral load. It is important to treat women living with HIV during pregnancy regardless of the clinical stage of disease or CD4 count and to retain them for postpartum care.

Pathophysiology

Understanding the life cycle of the virus is important to recognize how antiretroviral drugs are combined for optimal therapy (**Figure 87–1**). Once HIV enters the body, a surface envelope glycoprotein, gp120, binds to CD4 receptors found on the surface of dendritic cells, T-lymphocytes, monocytes, and macrophages. This binding triggers a conformational change that allows further binding to other chemokine receptors on the cell surface (C-C chemokine receptor type 5 (CCR5) and/or C-X-C chemokine receptor type 4 (CXCR4)). Greater than 95% of newly infected patients have viruses that preferentially use CCR5 to enter the cell, and most patients with advanced disease have viruses that preferentially use CXCR4 to enter the cell.

After the virus has attached to CD4 and chemokine receptors, another viral glycoprotein, gp41, assists with viral fusion to the cell and internalization of the viral contents. The viral contents include single-stranded ribonucleic acid (RNA), an RNA-dependent deoxyribonucleic acid (DNA) polymerase (also known as **reverse transcriptase**), and other enzymes. Using the single-stranded viral RNA as a template, reverse transcriptase synthesizes a complementary strand of DNA. The single-stranded viral RNA is removed from the newly formed DNA strand by ribonuclease H, and reverse transcriptase completes the synthesis of double-stranded DNA. The viral reverse transcriptase enzyme is highly error-prone and many mutations occur in the conversion of RNA to DNA, allowing HIV to rapidly develop drug resistance under selective pressure.

Chronic infection is established when the double-stranded DNA migrates to the host cell nucleus and is integrated into the host cell DNA by the viral enzyme **integrase**. Viral replication begins when the host CD4 cell becomes activated in the presence of antigens or cytokines. Host RNA polymerase transcribes viral DNA into genomic RNA and messenger RNA. After exiting the nucleus, the messenger RNA is translated into viral proteins using the host cell's ribosomes. The HIV **protease** enzyme cleaves large polypeptides into smaller functional proteins which, along with the viral genome, are assembled into immature virions along the

Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill; 2014; with permission.)

internal side of the cell's lipid bilayer. As the virion buds from the cell, it acquires a lipid envelope and surface proteins from the host cell. After budding, the virus continues final assembly and maturation, which then goes on to infect new CD4 cells. During the early stages of infection, approximately 10 billion virions can be produced each day. Most of the cells containing these viruses will be lysed as a result of budding virions, cytotoxic T-lymphocyte destruction, or apoptosis. However, HIV will be protected within some cells (macrophages, T cells in lymph nodes), which can stay dormant for years.

The initial immune response against HIV is relatively effective; however, it is unable to completely clear the infection, and the patient enters a latent, asymptomatic, or mildly symptomatic stage lasting 5 to 15 years. During this time, a high rate of viral replication can be seen in the lymph nodes but ultimately can occur in all sites of the body including protected sites such as the central nervous system (CNS) and genitalia. Replication is evident by a rise in circulating, detectable viral RNA, or viremia. It should be noted that this is a vulnerable period, whereby the infected, asymptomatic individual is often at high risk for transmitting the virus. Eventually, immune deficiency occurs when the body is no longer able to replenish helper T cells at a rate equal to that at which HIV is destroying them resulting in a progressive decline in the number of circulating CD4 lymphocytes.

KEY CONCEPT The goal of therapy is to maximally and durably suppress HIV replication to restore and preserve immune system function and minimize morbidity and mortality.

CLINICAL PRESENTATION AND DIAGNOSIS

HIV testing may involve blood draws, finger pricks, or oral swabs. Certain modalities are used only for screening, while others are required for confirmatory diagnosis. Accuracy of the tests is contingent upon both the specimen type and the target for detection. Antigen tests detect a HIV capsid protein called p24, which is highly specific and typically the first marker to rise following infection. As antibodies develop, typically 3 to 12 weeks after infection, p24 antigen concentrations wane. Nucleic acid tests detect viral RNA and provide a quantifiable result but are less routinely used for diagnosis due to cost.

Patients who are newly infected with HIV may be asymptomatic or present with nonspecific, or "flu-like" signs and symptoms such as fever, myalgias, arthralgias, lymphadenopathy, pharyngitis, and rash. This phase is known as acute, or primary, HIV infection and occurs as the body's natural response to infection. Symptoms last for an average of 14 days following transmission. Providers should consider the possibility of HIV infection in any patient with these findings and inquire about recent high-risk sexual encounters or other high-risk exposures. In acute infection, HIV RNA concentrations in blood and the genital tract are very high, increasing the risk of transmission to others. These patients will generally have plasma HIV RNA concentrations greater than 10^6 copies/mL (10^9 copies/L) in the absence of detectable anti-HIV antibodies. Therefore, both rapid and antibody-only based HIV tests may render a false negative result during acute infection. Increased infectiousness coupled with undiagnosed HIV infection in these patients may account for a substantial proportion of sexual HIV transmission.

If patients are not identified during acute infection, most people with HIV will recover from the initial symptoms and enter a phase of chronic, asymptomatic infection. During this period of clinical latency, the virus is active but reproduces at low levels. Over time, the virus will overwhelm the immune system and patients may progress to AIDS. If not diagnosed in the acute infection phase, patients may present later in the infectious course with nonspecific symptoms such as myalgias, fatigue, unexplained weight loss, thrush, or symptoms associated with opportunistic infections.

Diagnosis of HIV begins with a fourth generation combination immunoassay that detects HIV-1 and HIV-2 antibodies and HIV-1 p24 antigen. No further testing is required for specimens that are nonreactive. Specimens that are reactive on the initial immunoassay should be tested with an antibody immunoassay that differentiates HIV-1 from HIV-2 antibodies. Positive results of both the fourth generation immunoassay and differentiation tests confirm the diagnosis of HIV. Nonreactive or indeterminate specimens on the HIV-1/HIV-2 antibody differentiation immunoassay should be tested with an HIV-1 nucleic acid test (NAT). Positive testing results indicate the need for HIV medical care that includes additional testing such as HIV viral load and CD4 count to stage the disease and establish baseline values around which treatment goals are centered. At-home, HIV-1 test kits (eg, Home Access HIV-1 Test System, OraQuick) allow patients to self-collect blood or oral swab samples and obtain confidential results in the privacy of their home. Individuals with positive tests should contact a healthcare provider for follow-up testing. In the United States, 1 in 7 patients living with HIV are not aware of their status, thus identifying infected patients and providing referral into HIV care is critical for preventing HIV transmission.[7] Accordingly, the US CDC recommends that patients aged 13 to 64 years in all healthcare settings undergo opt-out HIV testing, meaning a separate consent form for testing is not needed after the patient has been informed that testing will be completed, at least once as part of routine care. For patients in the high-risk groups mentioned previously, HIV testing should be performed on an annual basis, and pregnant women should be tested with each pregnancy.[8]

KEY CONCEPT HIV treatment response and disease progression are determined by the following: (a) the CD4 T-lymphocyte count (CD4 count) and percentage and (b) plasma HIV RNA (viral load). The CD4 percentage is followed because the absolute count may fluctuate and does not necessarily indicate a change in the patient's condition.

TREATMENT

KEY CONCEPT The goals of treatment are to maximally and durably suppress viral replication, restore and preserve immune function, reduce HIV-associated morbidity and prolong the duration and quality of survival, and prevent disease transmission. Elimination or cure of HIV is not possible with currently available therapies. Instead, maximal suppression of viral replication (defined as plasma HIV RNA concentrations undetectable by the most sensitive assay available) is the most important indicator of response to drug therapy and serves to prevent transmission to others. After the initiation of combination antiretroviral therapy (ART) (cART), a rapid decline to undetectable plasma HIV RNA in 12 to 24 weeks is a predictor of improved clinical outcomes.[9] Routine viral load testing is recommended to ensure a sustained response.

KEY CONCEPT Degree of immune function preservation is also correlated with decreased viral replication and is measured by CD4 T-cell counts. The CD4 count is the best predictor of progression to AIDS and helps clinicians determine when to initiate opportunistic infection prophylaxis. At CD4 T-cell counts of 200 cells/mm^3 (200×10^6/L) and lower, patients require chemoprophylaxis

Clinical Presentation and Diagnosis of HIV

Patients with acute HIV infection may display nonspecific, flu-like symptoms. Patients with chronic HIV infection may present with these same nonspecific symptoms and/or opportunistic infections.

Signs and Symptoms of Acute or Primary HIV

Patients may present with fever, fatigue, lymphadenopathy, pharyngitis, myalgias, arthralgias, diarrhea and/or rash. These symptoms typically subside within days to weeks. Some patients may remain asymptomatic.

Signs and Symptoms of AIDS

Patients may experience signs and symptoms similar to acute HIV but may seem exaggerated and prolonged. They may also experience weight loss, recurring fever or night sweats, hepatosplenomegaly, thrush, or neurologic symptoms (such as meningoencephalitis, aseptic meningitis, peripheral neuropathy, facial palsy, cognitive impairment, or psychosis).

Opportunistic Infections

Depending on the severity of immunosuppression (the CD4 count), patients may present with the following opportunistic infections (grouped by CD4 count):

- _Any CD4 count_
  - _Mycobacterium tuberculosis_ disease*
  - Bacterial pneumonia (commonly _Streptococcus pneumoniae, Haemophilus influenzae_)**
  - Herpes simplex virus disease**
  - Varicella zoster virus disease
  - Bacterial enteric disease (most commonly _Salmonella, Campylobacter_, and _Shigella_)**
  - Syphilis
  - Bartonellosis
- _Less than 200 cells/mm^3 (200×10^6/L)_
  - Coccidioidomycosis**
  - _Pneumocystis jiroveci_ pneumonia (PCP or PJP)*
  - Oropharyngeal and esophageal* candidiasis
  - Kaposi sarcoma* or human herpesvirus-8 disease
- _Less than 150 cells/mm^3 (150×10^6/L)_
  - Disseminated histoplasmosis*
- _Less than 100 cells/mm^3 (100×10^6/L)_
  - _Toxoplasma gondii_ encephalitis*
  - Cryptosporidiosis**
- _Less than 50 cells/mm^3 (50×10^6/L)_
  - Disseminated _Mycobacterium avium_ complex disease*
  - Cytomegalovirus disease (CMV)**
  - Cryptococcosis**

*AIDS-defining condition.
**AIDS-defining condition if certain criteria are met.

for opportunistic infections. Table 87–1 details the monitoring points of HIV treatment for plasma HIV RNA and CD4 T-cell counts. In addition to these parameters, basic blood chemistry tests, liver function tests (LFTs), complete blood counts, and lipid profiles should be monitored every 3 to 12 months in patients receiving ART.[9]

Eight classes of drugs are available to treat HIV infection: nucleoside/nucleotide reverse transcriptase inhibitors (NRTI), nonnucleoside reverse transcriptase inhibitors (NNRTI), integrase strand transfer inhibitors (INSTI), protease inhibitors (PIs), a fusion inhibitor, a CCR5 antagonist, a CD4 post-attachment inhibitor, and a gp120 attachment inhibitor. Pharmacokinetic enhancers or "boosters" including ritonavir and cobicistat may be added to a regimen in order to slow the metabolism and thus enhance efficacy of certain antiretroviral agents. **KEY CONCEPT** Generally, cART consists of three or more active drugs at any CD4

Table 87–1

Monitoring End Points for CD4 T-Cell Counts and HIV RNA

CD4$^+$ T Cell Count		Plasma HIV-1 RNA	
When to Monitor?	**Why?**	**When to Monitor?**	**Why?**
Initial diagnosis	Assess immune function and urgency to initiate cART Assess need for OI prophylaxis	Entry to care or before initiating cART	Establish baseline Provide prognostic information May impact treatment selection
3 months after cART initiation	Assess degree of immune reconstitution	2–8 weeks after starting or modifying cART due to treatment failure	Confirm adequate initial response to regimen
Every 3–6 months	Monitor success of treatment and need for OI prophylaxis in patients receiving cART Assess urgency to initiated cART and need for OI prophylaxis in untreated patients	4–8 weeks after modifying cART in virally suppressed patients	Confirm effectiveness of switch therapy
		Every 3–6 months	Confirm continuous viral suppression in patients receiving cART

Patient Encounter 1, Part 1: Treatment Initiation

A 23-year-old African American man presents to your clinic with complaints of weight loss, nausea and vomiting, fatigue, and rash. During a detailed social history, you learn that for the past 5 years, he has had many unprotected sexual encounters with men and women. His last HIV test was 2 years ago which was negative. He does not use IV drugs but does smoke marijuana. Based on his presentation and risk factors today, you decide to perform general STI as well as HIV testing.

PMH: Seizure disorder and previously treated for gonorrhea 3 years ago

FH: Mother—coronary artery disease, lung cancer; Father—HTN, type II diabetes

SH: Full-time college student, part-time retail store clerk; sexual history as above with no condom use. He reports moderate (three to four times weekly) marijuana use.

Meds: Multivitamin daily, carbamazepine 400 mg twice daily

Allergies: Latex (rash)

ROS: Positive for weight loss, decreased appetite; Negative for shortness of breath, cough, chest pain, nausea, vomiting, diarrhea

PE:

Within normal limits

VS: BP 120/65 mm Hg, P 75 beats/min, RR 18 breaths/min, T 37.5°C

HEENT: Thrush, lymph nodes (+) lymphadenopathy

CV: RRR, normal S1, S2; no murmurs, rubs, gallops

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly

Rectal: Deferred

Labs: Sodium 140 mEq/L (140 mmol/L), potassium 4.0 mEq/L (4.0 mmol/L), chloride 102 mEq/L (102 mmol/L), bicarbonate 25 mEq/L (25 mmol/L), blood urea nitrogen 10 mg/dL (3.57 mmol/L), creatinine 0.7 mg/dL (62.9 μmol/L), WBC $8 \times 10^3/\text{mm}^3$ (8×10^9/L), hemoglobin 11.4 g/dL (114 g/L or 7.07 mmol/L), hematocrit 32% (0.32), platelets $79 \times 10^3/\text{mm}^3$ (79×10^9/L), neutrophils 45% (0.45), bands 9% (0.09), lymphocytes 20% (0.20), monocytes 1% (0.01), eosinophils 1% (0.01), basophils 0% (0.00)

count, which increases the durability of viral suppression and decreases the potential for the development of resistance. Traditional treatment regimens include at least three drugs: two NRTIs given with an INSTI, a PI (plus a pharmacokinetic enhancer), or an NNRTI. Data now also support the use of select two-drug regimens for initial or consolidation therapy under certain circumstances. Combination regimens suppress HIV viral loads in 80% to 90% of patients in clinical trials.[9] Therefore, monotherapy with any agent or the use of NRTIs without another drug class are not recommended treatment options. Enfuvirtide, a fusion inhibitor, and ibalizumab, a post-attachment inhibitor, are only Food and Drug Administration (FDA)-approved for use in treatment-experienced patients when other options are not available due to drug resistance. Figure 87–1 details the mechanisms of action of the drug classes within the life cycle of HIV.

KEY CONCEPT Patient adherence is a key component to treatment success. In patients living with HIV, drug therapy is required indefinitely, as the virus begins to replicate at high levels when medications are stopped. Combination therapy used in the past for HIV was exceedingly complicated for patients with multiple daily doses, varying food restrictions, and large pill burdens. Advances in delivery and formulations now make possible once- or twice-daily dosing with fewer pills per day. Refer to Table 87–2 for a list of single-tablet HIV regimens. These advances, however, do not replace the need for patient counseling by a trained pharmacist and a multidisciplinary approach to promoting adherence.

Nonpharmacologic Interventions

All patients should be counseled initially and repeatedly on ways to prevent viral transmission. In 2016, only 51% of people living with HIV in the United States had maximally suppressed viral loads.[9] Nonsuppressed individuals can still transmit the virus to sexual partners or those with whom they share needles or other drug equipment. In contrast, patients with an undetectable viral load nearly eliminate the risk of sexual transmission to their partners. In instances where both partners are living with HIV, safe sex and needle practices reduce the risk of superinfection with differing strains of HIV and the transmission of other sexually transmitted infections (STIs). General guidelines for preventing viral transmission include using condoms with a water-based lubricant for vaginal or anal intercourse, using condoms without lubricant or dental dams for oral sex, and avoiding the use of shared, nonsterile equipment used to prepare, inject, or inhale

Table 87–2

Complete Single Pill Regimens

Atripla	Efavirenz + tenofovir disoproxil fumarate + emtricitabine
Biktarvy	Bictegravir + tenofovir alafenamide + emtricitabine
Complera	Rilpivirine + tenofovir disoproxil fumarate + emtricitabine
Delstrigo	Doravirine + tenofovir disoproxil fumarate + lamivudine
Dovato	Dolutegravir + lamivudine
Genvoya	Elvitegravir + cobicistat + tenofovir alafenamide + emtricitabine
Juluca	Dolutegravir + rilpivirine
Odefsey	Rilpivirine + tenofovir alafenamide + emtricitabine
Stribild	Elvitegravir + cobicistat + tenofovir disoproxil fumarate + emtricitabine
Symfi/Symfi Lo	Efavirenz + tenofovir disoproxil fumarate + lamivudine
Symtuza	Darunavir + cobicistat + tenofovir alafenamide + emtricitabine
Triumeq	Dolutegravir + abacavir + lamivudine

drugs. Treating other STIs in patients living with HIV may also help to prevent HIV transmission. The presence of STIs increases genital tract HIV viral load and, correspondingly, the risk of HIV transmission to sexual partners.

KEY CONCEPT Nutrition and dietary counseling should also be included in the care of the HIV patient, as poor nutrition leads to poorer outcomes and complicates treatment. ART itself may introduce nutritional considerations, including drug–food interactions, gastrointestinal (GI) adverse effects that may affect appetite and limit dietary intake, weight gain, lipid abnormalities, and fat redistribution. The American Dietetic Association currently recommends assessing HIV-infected patients for their level of nutritional risk and involving a registered dietician as part of the clinical team for optimal nutrition care.[10]

Further, the coordination of care and management of mental and psychosocial determinants of health, such as active substance abuse, depression, and anxiety, are paramount in the success of HIV control.

Pharmacologic Therapy for Antiretroviral-Naïve Patients

Two expert panels publish guidelines for the treatment of HIV-infected individuals. Although the recommendations are quite similar, slight differences do exist between the Department of Health and Human Services (DHHS) Guidelines[9] and the International Antiviral Society—USA (IAS-USA) Panel Recommendations.[11] The DHHS Guidelines are updated frequently, and current and archived versions are available online at www.aidsinfo.nih.gov. Due to the intense research and constant modifications to therapeutic approaches in the treatment of HIV, the majority of the treatment algorithms and recommendations presented herein follow the most up-to-date information found in the June 2021 DHHS recommendations.

KEY CONCEPT ART is recommended in all patients living with HIV (regardless of CD4 count), as soon as possible following diagnosis, in order to reduce the morbidity and mortality associated with HIV infection and prevent HIV transmission. This recommendation, updated in 2015, supercedes previous stipulations that were based on CD4+ cutoffs, and now reflect the proven benefit of ART in all patients, irrespective of disease severity. Patients should understand the importance of adherence and commit to ART indefinitely. Urgency is heightened in patients with AIDS-defining conditions, acute or recent HIV infection, and who are pregnant.[9] Once the decision is made to initiate treatment, the regimen is selected based on patient-specific factors such as baseline viral load and CD4 count, comorbidities, individual preferences, anticipated adherence, and medication accessibility. **KEY CONCEPT** Currently, based on high their potency and strong safety profiles, all of the preferred regimens for initial treatment contain an INSTI in combination with one or two NRTIs. The recommended agents are shown in Table 87–3.

Drug resistance testing should be performed at diagnosis and again prior to initiating treatment if treatment is deferred (see "Pharmacologic Therapy for Antiretroviral-Experienced Patients" section for further discussion of drug resistance testing). The results of resistance testing may dictate which drugs or drug classes are preferred, as approximately 10% to 17% of ART-naive patients will have drug-resistant virus.[9] This initial resistance pattern often involves the NRTIs or NNRTIs but may involve other drug classes. In general, INSTI-based regimens have the advantage of avoiding many complex drug–drug interactions and toxicities seen with NNRTIs and PIs. If transmitted INSTI resistance is a concern, integrase resistance testing must be specified as standard HIV genotyping only includes the protease and reverse transcriptase genes.

Table 87–3

Recommended Initial ART Regimen Options for Most Patients Living with HIV, Regardless of Pre-ART Viral Load or CD4 Cell Count[8]

INSTI-Based Regimen:

Bictegravir/tenofovir alafenamide/emtricitabine (AI)

Dolutegravir/abacavir/lamivudine *(Only for patients who are HLA-B*5701 negative)* (AI)

Dolutegravir + tenofovir alafenamide OR tenofovir disoproxil fumarate + emtricitabine OR lamivudine (AI)

Dolutegravir/lamivudine (*except for patients with HIV RNA >500,000 copies/mL, HBV coinfection, or are pending HIV genotypic resistance testing for reverse transcriptase or HBV testing)* (AI)

ART, Antiretroviral therapy; HIV, human immunodeficiency virus.

Rating of Recommendations: A = Strong; B = Moderate.

Rating of Evidence: I = data from randomized controlled trials; II = Data from well-designed nonrandomized trials, observations cohort studies with long-term clinical outcomes, relative bioavailability/bioequivalence studies, or regimen comparisons from randomized switch studies.

If abacavir is included in a regimen, patients should undergo human leukocyte antigen (HLA)-B*5701 testing prior to initiation to assess the risk of abacavir hypersensitivity, a multiorgan clinical syndrome that often presents soon after treatment initiation. Studies suggest a slightly higher risk in White patients (5%–8%) in comparison to Black patients (2%–3%).[9] Patients who test positive for the allele are at high risk of developing this reaction and should not be prescribed abacavir.[9] An abacavir allergy should also be documented in the patient's medical record to prevent future administration. Those patients with a negative test may receive abacavir but should still be counseled and monitored for the development of hypersensitivity. Tenofovir alafenamide (TAF) is a new prodrug formulation of tenofovir that achieves high intracellular conentations and significantly lower plasma exposure. This pharmacokinetic difference presumably explains why TAF is associated with less nephrotoxicity and impact on bone mineral density than its predecessor tenofovir disoproxil fumarate (TDF) and may be preferable from a toxicity standpoint.

In patients who cannot tolerate the recommended initial regimens for most patients living with HIV, or have a compelling reason to choose a different agent, the following alternative regimens are recommended (Table 87–4).[9]

PI-based regimens, particularly containing darunavir, may be preferable in patients in whom adherence is a concern or drug resistance results are pending given the high overall resistance barrier of this class, though drug interactions, the need for boosting agents, and toxicities must also be considered. NNRTI-based regimens are associated with lower pill burden and decreased incidence of long-term adverse effects (eg, dyslipidemia) in comparison with some PI-based regimens. However, this class also has a low threshold for drug resistance (the K103N mutation causes high-level cross-class resistance), and patient adherence is a critical consideration. Regimens with demonstrated efficacy but limited by other factors such as toxicities or pill burden are also provided in the guidelines. One of these regimens should only be selected if a first-line or alternate regimen is intolerable or the patient has a compelling reason to avoid drugs in a first-line or alternate regimen. The guidelines also include a list of therapies *not recommended* for initial treatment due

Table 87–4

Recommended Initial cART Regimen Options in Certain Clinical Situations

PI-Based Regimens:

Darunavir/cobicistat OR darunavir/ritonavir + tenofovir alafenamide OR tenofovir disoproxil fumarate + emtricitabine OR lamivudine (AI)

Atazanavir/cobicistat OR atazanavir/ritonavir + tenofovir alafenamide OR tenofovir disoproxil fumarate + emtricitabine OR lamivudine (BI)

Darunavir/cobicistat OR Darunavir/ritonavir + abacavir/lamivudine *(Only for patients who are HLA-B*5701 negative)* (BII)

NNRTI-Based Regimens:

Doravirine/tenofovir disoproxil fumarate/lamivudine (BI) or doravirine/tenofovir alafenamide/emtricitabine (BIII)

Efavirenz 600 mg + tenofovir disoproxil fumarate + emtricitabine OR lamivudine (BI)

Efavirenz 400 mg/tenofovir disoproxil fumarate/lamivudine (BI)

Efavirenz 600 mg + tenofovir alafenamide/emtricitabine (BII)

Rilpivirine/(tenofovir alafenamide OR tenofovir disoproxil fumarate)/emtricitabine (If HIV RNA < 100,000 copies/mL and CD4 > 200 cells/mm^3) (BI for TDF, BII for TAF)

INSTI-Based Regimen:

Elvitegravir/cobicistat/(tenofovir alafenamide OR tenofovir disoproxil fumarate)/emtricitabine (BI) Raltegravir + tenofovir alafenamide OR tenofovir disoproxil fumarate + emtricitabine OR lamivudine (BI for TDF, BII for TAF/FTC)

cART, combination antiretroviral therapy; HIV, human immunodeficiency virus; RNA, ribonucleic acid.

Rating of Recommendations: A = Strong; B = Moderate.

Rating of Evidence: I = data from randomized controlled trials; II = Data from well-designed nonrandomized trials, observations cohort studies with long-term clinical outcomes, relative bioavailability/bioequivalence studies, or regimen comparisons from randomized switch studies; III Expert opinion.

to suboptimal potency, significant toxicity, or other pharmacological concerns. It is also noteworthy that certain drug combinations may require dosage adjustments due to pharmacokinetic changes. Drug formulations, commonly prescribed doses, and other considerations for single agent and combination tablets are provided in Tables 87–5 and 87–6.

Pharmacologic Therapy for Antiretroviral-Experienced Patients

KEY CONCEPT Ongoing viral replication, whether at low levels (plasma HIV RNA < 200 copies/mL) in the face of adequate drug concentrations or at higher levels due to inconsistent systemic concentrations (or low concentrations in sanctuary sites, eg, male and female genital fluids, cerebrospinal fluid, or lymph nodes), will eventually lead to resistance to the prescribed medications. To avoid further progression of resistant mutations, drug resistance testing should be performed and then a failing regimen should be discontinued as soon as possible.[9] The goal of therapy for patients with antiretroviral resistance is to reestablish virologic suppression or plasma HIV RNA lower than the limit of detection of the assay (typically < 40 copies/mL [40 × 10^3 copies/L]).

Treatment considerations for antiretroviral-experienced patients are much more complex than for patients who are naïve to therapy. Prior to changing therapy, the reasons for treatment failure should be identified. A comprehensive review should be performed of the patient's severity of disease, antiretroviral treatment history, adherence to therapy, intolerance or toxicity, concomitant drug therapies, comorbidities, and results of current and past HIV resistance testing. If patients fail therapy due to poor adherence, the underlying reasons must be determined and addressed prior to initiation of a new regimen. Reasons for poor adherence may include problems with medication access, active substance abuse, depression and/or denial of the disease, and a lack of education on the importance of 100% adherence to therapy. Medication intolerance or toxicity can be remedied with therapy for the adverse event, exchanging the drug causing the toxicity with another in the same class, or changing the entire regimen. Pharmacokinetics or systemic drug exposure can be optimized by ensuring maximal drug absorption (taking the drug with or without food can alter exposure by up to 30%) and avoiding interactions with concomitant prescription or nonprescription medications and dietary supplements.

Patient Encounter 1, Part 2

After receiving the diagnosis of HIV and assessing his laboratory values and willingness to initiate therapy, the patient from Part 1 and his medical team decide to start antiretroviral therapy.

What is the guidance for when to start therapy in a treatment-naïve patient?

What are the recommended regimens according to the DHHS Guidelines?

What is the potential for drug interactions with each of the recommended regimens?

Which concomitant medication complicates initiating therapy in this patient and what are possible ways to manage such drug interactions?

What adverse effects does the patient need to be counseled on with each of the recommended regimens?

Drug interactions between different antiretroviral agents and between antiretrovirals and concomitant medications should be evaluated for each patient to avoid under- and/or overexposure of either therapy. KEY CONCEPT NNRTIs, PIs, certain INSTIs, and maraviroc are metabolized by CYP-450 enzymes. In addition, NNRTIs, PIs, and cobicistat are inhibitors and/or inducers of this enzyme system. Some of the antiretrovirals are substrates, inhibitors, and/or inducers of transporters such as P-glycoprotein (P-gp) and, therefore, may lead to drug interactions. Information provided in Table 87–7 describes the drug interaction potential of each antiretroviral. Due to ever-changing drug interactions, the regularly updated DHHS Guidelines for the Use of Antiretroviral Agents in HIV-1–Infected Adults and Adolescents are a recommended source of specific drug interactions.[9]

It is reasonable to expect maximal viral suppression in patients with limited drug exposure. However, this may not be feasible for patients with prior exposure to multiple medications. In antiretroviral-experienced patients, a reasonable goal is to minimize toxicity, preserve immune function and prevent clinical progression.

Several issues need to be considered in choosing a salvage regimen for HIV infection. Knowing prior medication exposure can assist in identifying which drugs to avoid. However, direct HIV resistance testing can better identify the resistance and susceptibility patterns of the major viral strains. Two types of HIV

Table 87–5

Summary of Currently Available, Commonly Used Antiretroviral Products[a]

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events
Nucleoside (Tide) Reverse Transcriptase Inhibitors					
Abacavir (Ziagen)	300-mg tablet; 20-mg/mL oral solution	300 mg twice daily or 600 mg once daily	Child Pugh Class A: 200 mg twice daily Child Pugh Class B or C: contraindicated	None (alcohol increases abacavir conc. by 41%)	Potentially fatal hypersensitivity reaction (rash, fever, malaise, nausea, vomiting, shortness of breath, sore throat, loss of appetite)—HLA B*5701 test before treatment
Emtricitabine (Emtriva)	200-mg capsule; 10-mg/mL oral solution	200 mg daily; 240 mg oral solution daily	**CrCl (mL/min [mL/s]):** **Capsule:** **Solution:** 30–49 [0.50–0.82] 200 mg every 48 hours 120 mg every 24 hours 15–29 [0.25–0.49] 200 mg every 72 hours 80 mg every 24 hours < 15/HD [0.25/HD] 200 mg every 96 hours 60 mg every 24 hours Dose after dialysis on dialysis days	None	Minimal
Lamivudine (Epivir)	150- and 300-mg tablets, 10-mg/mL oral solution	150 mg twice daily or 300 mg once daily	**CrCl (mL/min [mL/s]):** **Dose:** 30–49 [0.50–0.82] 150 mg every day 15–29 [0.25–0.49] 150 mg, then 100 mg every day 5–14 [0.08–0.24] 150 mg, then 50 mg every day < 5/HD [0.08/HD] 50 mg, then 25 mg every day	None	Minimal
Tenofovir disoproxil fumarate (Viread)	150-, 200-, 250-, 300-mg tablet; 40 mg per 1 g powder	300 mg once daily	**CrCl (mL/min [mL/s]):** **Dose:** 30–49 [0.50–0.82] 300 mg every 48 hours 10–29 [0.17–0.49] 300 mg twice weekly ESRD/HD 300 mg every 7 days	Powder taken with food	Asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density
Tenofovir alafenamide (Vemlidy) *Of note, only FDA labeled for HBV infection, not HIV*	25-mg tablet	25 mg once daily	Do not use with CrCl < 15 mL/min (0.25 mL/s)	With food	Headache
Zidovudine (Retrovir)[b]	100-mg capsule, 300-mg tablet, 10-mg/mL IV solution, 10-mg/mL oral solution	300 mg twice daily	100 mg three times daily or 300 mg once daily in severe renal impairment (CrCl < 15 mL/min [0.25 mL/s]) or HD	None	Bone marrow suppression: macrocytic anemia or neutropenia; GI intolerance, headache, insomnia, asthenia

Nonnucleoside Reverse Transcriptase Inhibitors					
Doravirine (Pifeltro)	100-mg tablets	100 mg once daily If taken with rifabutin: Increase doravirine to 100 mg twice daily (every 12 hours) while on rifabutin	No dosage adjustments recommended	None	Rash; Sleep disorders, dizziness, altered sensorium, depression, suicidality; weight gain
Efavirenz (Sustiva)	50-, 200-mg capsules or 600-mg tablet	600 mg daily at or before bedtime	Use with caution in patients with hepatic impairment	Take on an empty stomach high-fat/calorie meals increases C_{max} of capsule 39% and C_{max} of tablet 79%	Rash; CNS symptoms (insomnia, irritability, lethargy, dizziness, vivid dreams) usually resolve in 2 weeks; increased LFTs; false-positive cannabinoid test; teratogenic in monkeys
Etravirine (Intelence)	25-, 100-, 200-mg tablets	200 mg twice daily following a meal	No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C	Take following a meal. Fasting decreases systemic exposure by 50%.	Rash, nausea
Nevirapine (Viramune, Viramune XR)[b]	200-mg tablet, 100 and 400-mg XR tablet or 50-mg/5-mL oral suspension	200 mg once daily for 14 days; then 200 mg twice daily. For XR tablet, lead-in with 200 mg once daily of IR tablet followed by 400 mg daily XR tab not recommended for initiation in the following groups unless benefit outweighs the risk: 1) adult females with CD4 cell counts > 250 cells/mm^3 2) adult males with CD4 cell counts > 400 cells/mm^3	Use with caution in patients with hepatic impairment; avoid use with moderate to severe hepatic impairment	No food restrictions	Rash including Stevens–Johnson syndrome; symptomatic hepatitis, including fatal hepatic necrosis
Rilpivirine (Edurant)	25-mg tablet	25 mg daily	No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C; use with caution in severe or end-stage renal impairment	Take with food (a normal- to high-calorie meal) Absorption dependent on gastric pH-special considerations needed when coadministered with antacids	Rash; depressive disorders
Protease Inhibitors					
Atazanavir (Reyataz)	150-, 200-, 300-mg capsules, 50-mg oral packet	Atazanavir 300 mg + ritonavir 100 mg or cobicistat 150 mg OR atazanavir 400 mg daily If taken with efavirenz in treatment of naïve patients only: atazanavir 400 mg daily + ritonavir 100 mg daily (do not use with	Child-Pugh Class C: Not recommended Treatment-naïve patients on hemodialysis: atazanavir 300 mg + ritonavir	Take with food (AUC increases 30%); pH-sensitive dissolution—special considerations needed when coadministered with antacids	Indirect hyperbilirubinemia; prolonged PR interval (asymptomatic first-degree AV block); use with caution in patients with underlying conduction defects or on concomitant medications that can cause PR prolongation; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia

(*Continued*)

Table 87–5

Summary of Currently Available, Commonly Used Antiretroviral Products[a] (*Continued*)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events
		efavirenz in treatment of experienced patients)	100 mg daily; treatment-experienced patients on hemodialysis: Not recommended		
Darunavir (Prezista)	75-g, 150-mg, 600-mg, 800-mg tablets, 100-mg/mL oral suspension	Darunavir 600 mg twice daily + ritonavir 100 mg twice daily in treatment experienced patients with at least one darunavir resistance-associated substitution OR if genotypic testing is not possible Darunavir 800 mg daily + ritonavir 100 mg or cobicistat 150 mg daily in treatment naïve patients	Use with caution in patients with hepatic impairment	Take with food	Skin rash (has a sulfonamide moiety, Stevens–Johnson and erythema multiforme have been reported); diarrhea, nausea; headache; hyperlipidemia; transaminase elevation; hyperglycemia; fat maldistribution; possible increased bleeding episodes in patients with hemophilia
Ritonavir (Norvir)	100-mg tablet or capsule, 80-mg/mL solution (contains 43% alcohol)	100–200 mg/dose when used as pharmacokinetic enhancer	No dosage adjustment in mild hepatic impairment No data for moderate-to-severe impairment; use with caution	Take with food to improve tolerability	GI intolerance, nausea, diarrhea; paresthesias; hyperlipidemia; hepatitis; asthenia; taste perversion; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs
Fusion Inhibitors					
Enfuvirtide (Fuzeon)	Injectable, in lyophilized powder Each single-use vial contains 108 mg of enfuvirtide to be reconstituted with 1.1 mL of sterile water for injection for delivery of approximately 90 mg/1 mL	90 mg (1 mL) subcutaneously twice daily	No dosage recommendation	N/A	Local injection site reaction (pain, erythema, induration, nodules and cysts, pruritus, ecchymosis) in most patients; increased rate of bacterial pneumonia; < 1% hypersensitivity reaction (rash, fever, nausea, vomiting, chills, rigors, hypotension, or elevated serum transaminases); do not rechallenge

CD4 Post-attachment Inhibitor						
Ibalizumab (Trogarzo)	200 mg/1.33 mL (150 mg/mL) in a single dose vial	2 g IV as a single dose over 30 minutes followed by a maintenance dose of 800 mg IV over 15 minutes every 14 days thereafter	No renal or hepatic dose adjustments (has not been studied)	N/A	Scr abnormalities; rash; diarrhea	
Fostemsavir (Rukobia)	600-mg extended release tablet	600 mg twice daily	No renal or hepatic dose adjustments (has not been studied)	None	Increased AST/ALT; Increased serum creatinine	
Chemokine Receptor Antagonists (CCR5 Antagonists)						
Maraviroc (Selzentry)	25-, 75-, 150-, 300-mg tablets; 20 mg/mL oral solution	150 mg twice daily when given with strong CYP3A inhibitors (with or without CYP3A inducers) including PIs (except tipranavir/ritonavir) 300 mg twice daily when given with NRTIs, enfuvirtide, tipranavir/ritonavir, nevirapine and other drugs that are not potent P450 inhibitors 600 mg twice daily when given with CYP3A inducers, including efavirenz, rifampin, etc. (without a CYP3A inhibitor)	Patients with CrCl < 30 mL/min (0.83 mL/s) with a CYP3A inhibitor: Use contraindicated		No food restrictions	Abdominal pain; cough; dizziness; musculoskeletal symptoms; pyrexia; rash; upper RTI; hepatotoxicity; orthostatic hypotension
Integrase Inhibitors						
Dolutegravir (Tivicay)	10-,25-50 mg tablet; 5 mg soluble tablet (Tivicay PD)	50 mg daily if treatment naïve 50 mg twice daily if coadministered with efavirenz, fosamprenavir, tipranavir/ritonavir, rifampin OR if INSTI-experienced with known or suspected INSTI resistance If coadministered with etravirine, must add lopinavir/ritonavir, atazanavir/ritonavir or darunavir/ritonavir	Use with caution if CrCl < 30 mL/min (0.83 mL/s) No dosage adjustment for Child Pugh Class A or B Not recommended in Class C/has not been studied		Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn) OR may coadminster dolutegravir with calcium or iron supplements when taken together with food	Insomnia, depression, suicidality (primarily in patients with preexisting psychiatric conditions), headache; increased serum creatinine; increased CPK/rhabdomyolysis; hepatotoxicity in person coinfected with HBV or HCV; weight gain

---

[a]Note, this is not a comprehensive list of all available antiretroviral agents but represents the agents most commonly used based on guideline recommendations.

[b]Agents that may be utilized less commonly, still noteworthy at the time of publication.

ART, antiretroviral therapy; AUC, area under the time-concentration curve; AV, atrioventricular; C_{max}, maximum concentration; CrCl, creatinine clearance; ESRD, end-stage renal disease; HD, hemodialysis; INSTI, integrase strand transfer inhibitor; LFT, liver function test; NRTI, nucleoside/nucleotide reverse transcriptase inhibitor; UGT, uridine diphosphate-glucuronsyltransferase.

Adapted from Panel on Antiretroviral Guidelines for Adults and Adolescents. Guidelines for the Use of Antiretroviral Agents in HIV-1-Infected Adults and Adolescents [online]. Department of Health and Human Services. June 3, 2021. Available from: https://files.aidsinfo.nih.gov/contentfiles/lvguidelines/AdultandAdolescentGL.pdf.

Table 87–6

Summary of Currently Available, Commonly Used Combination Tablet Antiretroviral Agents[a]

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events
Nucleoside (Tide) Reverse Transcriptase Inhibitor Combination Tablets					
Zidovudine + lamivudine (Combivir)[b]	Zidovudine 300 mg + lamivudine 150-mg tablet	One tablet twice daily	Do not use with CrCl < 50 mL/min (0.83 mL/s)	None	Bone marrow suppression: macrocytic anemia or neutropenia; GI intolerance, headache, insomnia, asthenia
Abacavir + lamivudine + zidovudine (Trizivir)[b]	Abacavir 300 mg + lamivudine 150 mg + zidovudine 300-mg tablet	One tablet twice daily	Do not use with CrCl < 50 mL/min (0.83 mL/s)	None	Bone marrow suppression: macrocytic anemia or neutropenia; GI intolerance, headache, insomnia, asthenia Potentially fatal hypersensitivity reaction (rash, fever, malaise, nausea, vomiting, shortness of breath, sore throat, loss of appetite)—HLA B*5701 test before treatment
Abacavir + lamivudine (Epzicom)	Abacavir 600 mg + lamivudine 300-mg tablet	One tablet daily	Do not use with CrCl < 50 mL/min (0.83 mL/s)	None	Potentially fatal hypersensitivity reaction (rash, fever, malaise, nausea, vomiting, shortness of breath, sore throat, loss of appetite)—HLA B*5701 test before treatment
Tenofovir disoproxil fumarate + lamivudine (Cimduo)	Tenofovir disoproxil fumarate 300 mg + lamivudine 300 mg	One tablet daily	Do not use with CrCl < 50 mL/min (0.83 mL/s)	None	Asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density
Tenofovir disoproxil fumarate + emtricitabine (Truvada)	Tenofovir disoproxil fumarate 300 mg + emtricitabine 200 mg	One tablet daily	**CrCl (mL/min [mL/s]):** **Dose**: 30–49 [0.50–0.82] One tablet every 48 hours 10–29 [0.17–0.49], ESRD/HD Not recommended	None	Asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density
Tenofovir alafenamide + emtricitabine (Descovy)	Tenofovir alafenamide 25 mg + emtricitabine 200 mg	One tablet daily	**CrCl (mL/min [mL/s]):** **Dose**: <30 [0.5] Not recommended ESRD on HD One tablet once daily after HD	None	Headache
Nonnucleoside Reverse Transcriptase Inhibitor Combination Tablets					
Tenofovir disoproxil fumarate + emtricitabine + efavirenz (Atripla)[b]	Tenofovir disoproxil fumarate 300 mg Emtricitabine 200 mg Efavirenz 600 mg	One tablet daily	Do not use in patients with CrCl < 50 mL/min (0.83 mL/s)	High-fat/high-caloric meals increase peak plasma concentrations of efavirenz capsules by 39% and efavirenz tablets by 79%; take on empty stomach	Rash; CNS symptoms (insomnia, irritability, lethargy, dizziness, vivid dreams) usually resolve in 2 weeks; increased LFTs; false-positive cannabinoid test; teratogenic in monkeys, asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density
Tenofovir disoproxil fumarate + emtricitabine + rilpivirine (Complera)[b]	Tenofovir disoproxil fumarate 300 mg Emtricitabine 200 mg Rilpivirine 25 mg	One tablet daily with a meal	Do not use in patients with CrCl < 50 mL/min (0.83 mL/s)	Take with food (preferably high-fat meal), avoid acid suppression	Rash; depressive disorders, asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density

Tenofovir alafenamide + emtricitabine + rilpivirine (Odefsey)	Tenofovir alafenamide 300 mg Emtricitabine 200 mg Rilpivirine 25 mg	One tablet daily with a meal	Do not use in patients with CrCl < 30 mL/min (0.5 mL/s)	Take with food (preferably high-fat meal), avoid acid suppression	Rash; depressive disorders, headache
Tenofovir disoproxil fumarate + lamivudine + doravirine (Delstrigo)	Tenofovir disoproxil fumarate 300 mg Lamivudine 300 mg Doravirine 100 mg	One tablet daily If taken with rifabutin: One tablet once daily plus additional 1 tablet doravirine 100 mg 12 hours later while on rifabutin	Use not recommended in patients with CrCl < 30 mL/min (0.5 mL/s) Child-Pugh Class C: No dose adjustments provided (has not been studied)	None	Rash; Sleep disorders, dizziness, altered sensorium, depression, suicidality; weight gain, asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density
Tenofovir disoproxil fumarate + lamivudine + efavirenz (Symfi, Symfi Lo)	Tenofovir disoproxil fumarate 300 mg Lamivudine 300 mg Efavirenz 400 mg (Symfi Lo) or 600 mg (Symfi)	Once tablet daily	Do not use in patients with CrCl < 50 mL/min (0.83 mL/s) or ESRD on HD	Take on an empty stomach, (preferably at bedtime)	Rash; CNS symptoms (insomnia, irritability, lethargy, dizziness, vivid dreams) usually resolve in 2 weeks; increased LFTs; false-positive cannabinoid test; teratogenic in monkeys, asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density
Protease Inhibitor Combination Tablets					
Atazanavir + cobicistat (Evotaz)	Evotaz: 300 mg atazanavir plus 150-mg cobicistat tablet	One tablet daily Do not use with abacavir and lamivudine if pre-antiretroviral therapy HIV RNA ≥ 100,000 copies/mL	Use is not recommended in hepatic impairment Hemodialysis: Not recommended	Take with food (AUC increases 30%); pH-sensitive dissolution—special considerations needed when coadministered with antacids	Indirect hyperbilirubinemia; prolonged PR interval (asymptomatic first-degree AV block); use with caution in patients with underlying conduction defects or on concomitant medications that can cause PR prolongation; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia
Darunavir + Cobicistat (Prezcobix)	Prezcobix: 800 mg darunavir + 150 mg cobicistat tablet	One tablet daily Do not use with abacavir and lamivudine if pre-antiretroviral therapy HIV RNA ≥ 100,000 copies/mL	Use with caution in patients with hepatic impairment	Take with food	Skin rash (has a sulfonamide moiety, Stevens–Johnson and erythema multiforme have been reported); diarrhea, nausea; headache; hyperlipidemia; transaminase elevation; hyperglycemia; fat maldistribution; possible increased bleeding episodes in patients with hemophilia
Darunavir + cobicistat + emtricitabine + tenofovir alafenamide (Symtuza)	Darunavir 800 mg + cobicistat 150 mg + emtricitabine 200 mg + tenofovir alafenamide 10 mg	One tablet once daily	Do not use in patients with CrCl < 30 mL/min (0.5 mL/s) ESRD on HD: One tablet once daily after HD on HD days Child-Pugh Class C: Not recommended	Take with food	As above, additionally asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density

(*Continued*)

Table 87–6

Summary of Currently Available, Commonly Used Combination Tablet Antiretroviral Agents[a] (*Continued*)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events
Lopinavir + ritonavir (Kaletra)[b]	Lopinavir 100 mg + ritonavir 25-mg tablet, Lopinavir 200 mg + ritonavir 50-mg tablet, lopinavir 400 mg + ritonavir 100-mg/5-mL oral solution (contains 42% alcohol)	Two 200/50-mg tablets or 5 mL twice daily, four 200/50-mg tablets once daily; with efavirenz or nevirapine: three tablets or 6.5 mL twice daily	Use with caution in patients with hepatic impairment Avoid once-daily dosing in HD	Take with food (AUC increases 48%–80%)	Nausea, vomiting, diarrhea; asthenia; hyperlipidemia; LFT elevation; hyperglycemia; fat maldistribution; increased bleeding episodes in hemophiliacs
Integrase Inhibitor Combination Tablets					
Dolutegravir + rilpivirine (Juluca)	Dolutegravir 50 mg + rilpivirine 25 mg	One tablet once daily in patient virologically suppressed on a stable antiretroviral regimen for ≥ 6 months with no history of treatment failure and no resistance to dolutegravir or rilpivirine If taken with rifabutin: One tablet once daily plus additional rilpivirine 25-mg tablet once daily while on rifampin	Use with caution if CrCl < 30 mL/min (0.83 mL/s) No dose adjustments for Child Pugh Class C	Administer with a normal-to-high calorie meal. Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn) OR may coadminster Juluca with calcium or iron supplements when taken together with food	Insomnia, depression, suicidality (primarily in patients with preexisting psychiatric conditions), headache; increased serum creatinine; increased CPK/rhabdomyolysis; hepatoxicity in person coinfected with HBV or HCV; weight gain, rash
Dolutegravir + Lamivudine (Dovato)	Dolutegravir 50 mg + lamivudine 300 mg	One tablet once daily	Do not use in patients with CrCl < 50 mL/min (0.83 mL/s) Not recommended in Child-Pugh Class C (has not been studied)	Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn) OR may coadminster Dovato with calcium or iron supplements when taken together with food	Insomnia, depression, suicidality (primarily in patients with preexisting psychiatric conditions), headache; increased serum creatinine; increased CPK/rhabdomyolysis; hepatoxicity in person coinfected with HBV or HCV; weight gain

Bictegravir + emtricitabine + tenofovir alafenamide (Biktarvy)	Bictegravir 50 mg + emtricitabine 200 mg + tenofovir alafenamide 25 mg	One tablet daily	Use not recommended if CrCl < 30 mL/min (0.83 mL/s)	Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn) OR may coadminster Biktarvy with calcium or iron supplements when taken together with food	Increased serum creatinine; weight gain; diarrhea, nausea; insomnia, depression, suicidality (primarily in patients with preexisting psychiatric conditions)
Elvitegravir + cobicistat + tenofovir disoproxil fumarate + emtricitabine (Stribild)[b]	Elvitegravir 150 mg + cobicistat 150 mg + tenofovir disoproxil fumarate 300 mg + emtricitabine 200-mg tablet	One tablet daily	CrCl < 70 mL/min (1.17 mL/s) at initiation of therapy: Not recommended CrCl < 50 mL/min (0.83 mL/s) during therapy: Continued use is not recommended	Take with food; separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn)	Nausea; diarrhea; proteinuria; increased serum creatinine, dyslipidemia, weight gain, insomnia, depression, suicidality
Elvitegravir + cobicistat + tenofovir alafenamide + emtricitabine (Genvoya)	Elvitegravir 150 mg + cobicistat 150 mg + tenofovir alafenamide 25 mg + emtricitabine 200-mg tablet	One tablet daily	Do not use if CrCl < 30 mL/min (0.5 mL/s) ESRD on HD: One tablet once daily, administer after HD on HD days	Take with food	Nausea; diarrhea; proteinuria; increased serum creatinine, dyslipidemia, weight gain, insomnia, depression, suicidality
Abacavir + lamivudine + Dolutegravir (Triumeq)	Abacavir 600 mg Lamivudine 300 mg Dolutegravir 50 mg	One tablet daily	Do not use if CrCl < 50 mL/min (0.83 mL/s) No dosage adjustment for Child Pugh Class A or B Not recommended in Class C/has not been studied		Insomnia, depression, suicidality (primarily in patients with preexisting psychiatric conditions), headache; increased serum creatinine; increased CPK/rhabdomyolysis; hepatoxicity in person coinfected with HBV or HCV; weight gain, HLA B*5701 test before treatment

[a]Note, this is not a comprehensive list of all available antiretroviral agents but represents the agents most commonly used based on guideline recommendations.

[b]Agents that may be utilized less commonly, still noteworthy at the time of publication.

ART, antiretroviral therapy; AUC, area under the time-concentration curve; AV, atrioventricular; C_{max}, maximum concentration; CrCl, creatinine clearance; ESRD, end-stage renal disease; HD, hemodialysis; INSTI, integrase strand transfer inhibitor; LFT, liver function test; NRTI, nucleoside/nucleotide reverse transcriptase inhibitor; UGT, uridine diphosphate-glucuronsyltransferase.

Table 87–7

Notable Drug–Drug Interaction Potential

Antiretroviral Agent	Mechanism of Drug Interaction
Nucleoside (tide) reverse transcriptase inhibitors	
Abacavir	UGT1A1 Substrate
Tenofovir alafenamide	P-gp substrate
Tenofovir disoproxil fumarate	P-gp substrate
Non-nucleoside reverse transcriptase inhibitors	
Doravirine	CYP3A4 and 3A5 substrate
Efavirenz	CYP 2B6, 2A6, 3A4 substrate; CYP3A4 inhibitor, CYP3A4, 2B6, 2C19 inducer
Etravirine	CYP3A4, 2C9, 2C19 substrate; CYP2C9, 2C19 inhibitor, CYP3A4 inducer
Nevirapine	CYP3A4, 2B6 substrate; CYP3A4, 2B6 inducer
Rilpivirine	Concentration decreased with increased gastric pH; CYP3A4 substrate
Protease inhibitors	
Atazanavir, atazanavir/cobicistat	Concentration decreased with increased gastric pH, P-gP substrate and inhibitor (atazanavir alone is also inducer); CYP3A4 substrate; CYP3A4, 2C8 inhibitor; UGT1A1 inhibitor
Atazanavir/ritonavir	Concentration decreased with increased gastric pH; P-gP substrate and inhibitor; CYP3A4, 2D6 substrate; CYP3A4, 2D6, 2C8 inhibitor; CYP1A2, 2B6, 2C8, 2C9, 2C19 inducer; atazanavir inhibits UGT1A1, ritonavir induces UGT1A1
Darunavir/cobicistat	CYP3A4 substrate; CYP3A4, 2D6 inhibitor
Darunavir/ritonavir	CYP3A4 and 2D6 substrate; CYP3A4, 2D6 inhibitor; CYP 1A2, 2B6, 2C8, 2C9, 2C19 inducer; UGT1A1 inducer
Lopinavir/ritonavir	P-gp substrate; CYP3A4, 2D6 substrate; CYP3A4 inhibitor; CYP 1A2, 2B6, 2C8, 2C9, 2C19 inducer; UGT1A1 inducer
CD4 Post-attachment Inhibitors	
Fostemsavir	CYP3A4 substrate, BCRP/ABCG2, and P-glycoprotein/ABCB1 substrate
Chemokine receptor antagonist	
Maraviroc	P-gp substrate; CYP3A4 substrate
Integrase Inhibitors	
Bictegravir	Concentration decreased by polyvalent cations (Ca, Mg, Al, Fe, Zn); P-gp substrate; CYP3A4 substrate; UGT1A1 substrate
Dolutegravir	Concentration decreased by polyvalent cations (Ca, Mg, Al, Fe, Zn); P-gp substrate; CYP3A4 substrate; UGT1A1 substrate
Elvitegravir/cobicistat	Concentration decreased by polyvalent cations (Ca, Mg, Al, Fe, Zn); P-gp inhibitor; CYP3A4 substrate; CYP3A4, 2D6 inhibitor; CYP2C9 inducer; UGT1A1 substrate
Raltegravir	Concentration decreased by polyvalent cations (Ca, Mg, Al, Fe, Zn); UGT1A1 substrate

resistance testing are available, an HIV genotype and an HIV phenotype. Genotyping involves detecting mutations by genetically sequencing the virus, whereas phenotyping determines the ability of the virus to replicate in the presence of varying antiretroviral concentrations. Phenotyping involves exposing a sample of a patient's HIV to antiretroviral drugs and directly measuring the ability of HIV to grow in the presence of these drugs to determine which drugs will have activity. Genotyping is more rapid and less costly than phenotyping but results in a list of mutations that may be more difficult to interpret than phenotyping. An HIV virtual phenotype report may also be obtained when genotypes are ordered.[9] This compares the patient's viral sequence to a database of matched genotypes and drug susceptibilities to estimate the patient's phenotype (the likely susceptibility of the patient's virus to different antiretrovirals). Web-based tools are available to assist with interpretation of resistance mutations (eg, Stanford University's HIV Drug Resistance Database; http://hivdb.stanford.edu/index.html). However, interpretation of genotype and phenotype reports is recommended in conjunction with practitioners with advanced infectious diseases training.

Resistance testing should be obtained when all patients enter into care, in patients with virologic failure on an antiretroviral regimen, or with suboptimal suppression after initiation of ART. Testing is generally preferred for antiretroviral naïve patients. For resistance testing to be useful, the patient should ideally have a plasma HIV RNA of at least 1000 copies/mL (1×10^6 copies/L) (testing can be considered down to a HIV RNA level of 500 copies/mL) and should be currently taking their antiretroviral medications (or be within 4 weeks of discontinuing ART). Generally, this viral concentration is necessary to yield reliable amplification of the virus, and the antiretroviral medications are needed because the dominant viral species reverts to wild-type within 4 to 6 weeks after medications are stopped.

Management of antiretroviral-experienced patients is complex, and expert opinion is advised before selecting therapy. KEY CONCEPT As with antiretroviral-naïve patients, at least two, and preferably three, fully active drugs should be prescribed.[9] Since considerable cross-resistance can occur between medications within an antiretroviral class, using drugs to which the patient has not been exposed may be insufficient. Complete cross-resistance occurs within the first generation of NNRTIs (nevirapine, delavirdine, and efavirenz), whereas the NRTIs and PIs have variable overlapping resistance patterns. For this reason, HIV resistance assays are important tools for choosing effective therapies. The use of antiretrovirals with unique mechanisms of action such as enfuvirtide (fusion inhibitor) or maraviroc (CCR5 antagonist) may be warranted as salvage therapy. If maraviroc is chosen, a tropism assay is a test that should be performed to determine if the patient's virus utilizes the CCR5 co-receptor to enter host cells (as opposed to CXCR4 co-receptors). Resistance testing for enfuvirtide can also be performed.

In heavily treatment-experienced patients with multidrug-resistant HIV infection failing treatment, two newer options that can be considered in combination with other antiretrovirals include ibalizumab (post-attachment inhibitor) or fostemsavir (gp120 attachment inhibitor). Ibalizumab is deferred for last-line therapy due to the need for IV therapy, higher cost, and currently limited data assessing safety and efficacy. Fostemsavir is the latest novel antiretroviral approved in July 2020, and serves an oral option that can be added to a failing regimen. Notably, drug resistance testing is not available for these two agents. If HIV suppression is not achieved with currently approved agents, consideration should be given to enrolling patients in clinical trials or expanded access programs utilizing investigational antiretroviral therapies. In all patients failing therapy with resistance to one or more drugs, expert consultation is needed as well as continued strong adherence support.

The above information details the management of antiretroviral-experienced patients who experience ongoing viral replication and treatment failure. However, treatment-experienced patients who achieve and maintain HIV virologic suppression may be switched to different regimens in an attempt to further optimize their regimen in terms of adverse effect profile, dosing frequency, and pill burden to name a few examples. Options include other three-drug regimens that are within- or between-classes, select two-drug regimens, and more recently, long-acting antiretroviral therapy. The first long-acting complete regimen is Cabenuva (cabotegravir and rilpivirine), a once-monthly injection FDA approved in January 2021. More information about Cabenuva and other strategies utilized for the optimization of ART in the setting of viral suppression can be found in the 2021 DHSS guidelines.

Given the complexity of selecting appropriate cART therapy and the ability of the virus to rapidly develop resistance, the concept of antiretroviral stewardship is important. Antiretroviral Stewardship encompasses practices aimed at improving antiretroviral medication use with the goal of minimizing medication errors related to cART and optimizing HIV treatment outcomes. Such efforts may entail routine review of patients admitted to an institution on antiretrovirals and provider education in order to ensure an appropriate and complete cART regimen is selected (with regards to drug, dose, formulation, administration considerations) and drug–drug interactions are minimized. Antiretroviral stewardship can have a significant impact on cART medication error prevention, with a medication error rate reduction rate of 12% to 35% demonstrated in studies, depending on the type of intervention implemented.[12,13]

Treatment Considerations in Special Populations

▶ *Acute HIV Infection*

Diagnosis of acute HIV infection is difficult, since many patients are asymptomatic or have nonspecific clinical symptoms similar to other common respiratory infections. The fourth generation antigen/antibody test increases the ability to detect acute HIV-1 infection, but no laboratory assay can detect HIV immediately after it is acquired.

Treatment of acute infection can decrease the severity of acute disease and decrease the viral set point; this may decrease progression rates and reduce the rate of viral transmission.[9] Limitations include an increased risk of chronic drug-induced toxicities and the development of viral resistance. Resistance testing should be performed prior to initiation of therapy due to an increase in transmitted resistance in antiretroviral naïve patients.[9]

Patients should be quickly engaged in care after HIV diagnosis and, in general, be initiated on cART as soon as possible. Data from the Ward 86 Rapid ART Program for Individuals with an HIV Diagnosis (RAPID) ART program at the University of California, San Francisco assessed 225 patients referred to immediate ART at diagnosis and showed that viral suppression rates were 92.1% over a median of 1.09 years at last recorded viral load.[14] While early cART can improve the rate of virological suppression, a short delay may be necessary in patients with some opportunistic infections to prevent a paradoxical worsening of a known infection or manifestation of a new infection, known as the immune reconstitution inflammatory syndrome (IRIS). Additionally, there is limited data on initiation of ART in a small subset of PLWHIV who maintain viral loads below detectable levels without initiation of cART, known as elite controllers.

▶ *Adolescent and Young Adult Patients*

Adolescents infected after puberty acquire HIV in similar ways to adults and are thus treated as adults. In this population, dosing of antiretroviral drugs should not be based on age, but on the Tanner stage (which considers external primary and secondary sexual characteristics).[9] Adolescents in early puberty should be dosed according to pediatric guidelines, whereas those in late puberty should be dosed as adults. During growth spurts, adolescents should be monitored closely for drug efficacy and toxicity, since rapid changes in weight can lead to altered drug concentrations. Adherence is of concern in this population due to denial of the disease, misinformation, distrust of healthcare professionals, low self-esteem, and a lack of family and/or social support. Additionally, asymptomatic patients this age find it more difficult to adhere to therapy while feeling well.

▶ *Pediatric Patients*

There are unique considerations in the treatment of HIV-infected children. Specific treatment guidelines exist,[15] but a thorough review is outside the scope of this chapter. Most children acquire HIV infection through perinatal transmission either in utero, intrapartum, or postpartum through breastfeeding, although antiretroviral interventions have dramatically reduced transmission rates.[9] ART research is limited in pediatric patients, as some drugs have no dosing recommendations for this population or are not available in a formulation that can be easily administered to children. Additionally, drug exposures can change dramatically during early childhood development due to altered drug-metabolizing enzyme and drug transporter activities.

▶ *Pregnancy, Women of Reproductive Potential, and Breastfeeding*

The goals of ART for women of reproductive age and pregnant women are the same as for other adult patients. Specific guidelines for pregnant women living with HIV are available.[16] For women trying to conceive, preferred regimens include dolutegravir, raltegravir, atazanavir/ritonavir, or darunavir/ritonavir plus TDF/emtricitabine, TDF/lamivudine, or abacavir/lamivudine. Whereas previous data showed a higher prevalence of neural tube defects in infants born to women receiving dolutegravir, updated data indicates that this difference is minimal and not statistically significant. This data from Botswana showed a difference in prevalence of neural tube defects between pregnant women receiving dolutegravir and those receiving non-dolutegravir based regimens of 0.09% (95% CI, –0.03, 0.30). (reference 17) Although dolutegravir is considered a preferred antiretroviral drug for women of childbearing potential, the risks and benefits should be discussed prior to administration of a dolutegravir-based regimen in this patient population.

If a woman is already virally suppressed on an antiretroviral regimen at the time she becomes pregnant, it is recommended that she remain on that regimen. Exceptions include women on two-drug regimens; such patients should switch regimens or add additional ART agents to these regimens. Other agents to consider switching include cobicistat-boosted elvitegravir, darunavir, or atazanavir due to pharmacokinetic changes in the second and third trimesters of pregnancy. If not already on ART, preferred therapies in pregnancy include atazanavir + ritonavir, darunavir + ritonavir, raltegravir, or dolutegravir all administered with a two-NRTI backbone (abacavir/lamivudine or TDF/emtricitabine or TDF/lamivudine). Alternate regimens include efavirenz or rilpivirine administered with a two-NRTI backbone. A dual nucleoside/nucleotide reverse transcriptase inhibitor (NRTI) backbone that includes one or more NRTIs with high levels of transplacental passage, if possible, is recommended. The goal of therapy is to reduce plasma HIV RNA below detectable levels and prevent MTCT of HIV. Limited data are available on some antiretroviral pharmacokinetics in pregnancy, with close plasma HIV RNA and CD4 monitoring warranted in the third trimester of pregnancy. Standard doses are currently recommended for most antiretroviral drugs, although higher doses of some PIs may be indicated depending on the trimester of pregnancy.

Efavirenz, nevirapine, and many ritonavir- or cobicistat-boosted PIs decrease the concentrations of different estrogens and/or progestins in oral contraceptives, which could lead to treatment failure.[9] For patients prescribed these drugs, barrier forms of contraception are preferred to prevent pregnancy. Atazanavir may be taken with oral contraceptives with extreme caution, as it can increase or decrease the exposure to estrogen and progesterone, depending on whether it is used in combination with ritonavir. Depo-Provera (medroxyprogesterone) is likely the safest alternative, as studies have shown no significant interactions between depot medroxyprogesterone acetate and antiretrovirals.[18] Maraviroc, raltegravir, elvitegravir/cobicistat, dolutegravir, and bictegravir have not shown clinically significant effects when used with oral contraceptives.

After delivery, mothers are strongly recommended not to breastfeed if safe alternatives are available. Due to widespread availability of formula feeding options in the United States, breastfeeding should be avoided.[19] In resource-limited settings, breastfeeding may be encouraged with concomitant use of ART.

▶ *Hepatitis B Coinfection*

Patients living with HIV coinfected with the hepatitis B virus (HBV) have higher concentrations of DNA and hepatitis B early antigen (HBeAg) and higher rates of HBV-associated liver disease than in patients with chronic HBV infection without HIV. Indications to initiate therapy for HBV/HIV coinfected patients are the same as in HIV-negative patients and are based on the HBV DNA level, serum alanine aminotransferase (ALT), and severity of liver disease. One option to treat HBV is nucleoside/tide analogs. Nucleoside/tide analogs that treat HBV but not HIV are adefovir and entecavir. Entecavir, however, exhibits minimal antiviral activity against HIV and should never be administered to coinfected patients who are not concurrently receiving fully suppressive HIV therapy. If given without suppressive antiretrovirals, entecavir can select for M184 resistance, leading to HIV resistance to emtricitabine and lamivudine. Nucleoside/tide analogs that are used to treat HBV and HIV are lamivudine, emtricitabine, and tenofovir. Combinations of TDF + emtricitabine, tenofovir alafenamide + emtricitabine or TDF + lamivudine should comprise the NRTI backbone of a fully suppressive regimen.[20] When changing HIV therapy in a patient with HBV viral suppression, the new regimen should also treat HBV; the lamivudine, emtricitabine, or tenofovir formulation should be continued for treatment of HBV in addition to the new HIV regimen.[9] Abrupt discontinuation of these antiretrovirals may result in significant hepatic injury due to the exacerbation of hepatitis B. Of note, HBV infection should not be treated if a patient is not being treated for HIV. Additionally, two-drug ART regimens are not recommended for person with active HBV infection.

Vaccination against HBV can effectively prevent transmission. If there is no record of vaccination, or immunization history is unknown, patients living with HIV should be vaccinated.

▶ *Hepatitis C Coinfection*

All patients living with HIV should be screened for hepatitis C virus (HCV) infection. Patients coinfected with HCV and HIV have an increased rate of progression to cirrhosis, decompensated liver disease, hepatocellular carcinoma, and death compared with monoinfected HCV alone.[20] All HCV/HIV coinfected patients should be considered for therapy. Comprehensive treatment guidelines for HIV/HCV-coinfected patients are available and reflect the rapidly evolving treatment options for HCV.[9,21] It is important to consider the potential for clinically significant drug–drug interactions when selecting an HCV regimen for a patient living with HIV on ART.

Patient Encounter 2

A 30-year-old Caucasian woman presents to your clinic requesting medication to prevent the transmission of HIV. She has seen commercials for two drugs but cannot remember the difference between them. She has entered with a new relationship with her partner who has disclosed that he is HIV positive. She is interested in PrEP and wants additional information regarding HIV transmission prevention. Her and he partner have not engaged in sexual activities but plan to in the future.

What additional information do you need to know before creating a treatment plan for this patient?

What laboratory tests do you recommend?

What pharmacologic and nonpharmacologic options are available for this patient to protect herself from acquiring HIV?

What monitoring assessments and follow-up would you recommend?

Patient Encounter 3

A 45-year-old woman with HIV and Hepatitis B (virologically suppressed) presents to your clinic for follow-up after initiating Reyataz (atazanavir) + Norvir (ritonavir) + Truvada (emtricitabine/tenofovir disoproxil fumarate) 8 months ago (baseline HIV viral load: 325,000 copies/mL (325 × 10^6 copies/L), CD4+ T cell count = 475 cells/mm^3 (475 × 10^6/L).

At her last appointment 1 month ago, her HIV viral load was < 20 copies/mL and CD4+ T-cell count = 780 cells/mm^3 (780 × 10^6/L). Today, her HIV viral load is 12,000 copies/mL (12 × 10^6 copies/L). Today, she complains of GERD and has been taking omeprazole for the past month. She also complains of noticeable yellowing of her eyes which she states is really bothering her.

Was this patient initiated on a first-line guideline-recommended treatment regimen for HIV?

What factors should be considered when trying to determine causes of virologic failure?

You decide to switch the patient's regimen due to side effects and her inability to take the medication as prescribed.

What additional laboratory tests should be obtained at this visit?

Given the patient's comorbidity, what agents should you try to include in this new regimen?

What are some important general counseling points for this patient?

What monitoring assessments and follow-up would you recommend?

Preexposure Prophylaxis (PrEP)

Multiple large-scale clinical trials in populations at highest risk for acquiring HIV have demonstrated that antiretrovirals, particularly TDF + emtricitabine, in combination with effective risk-reduction services (eg, counseling, access to condoms, and treatment of STI), reduce the rate of HIV transmission. Data from these trials have led to the FDA approval of Truvada (fixed-dose combination of TDF 300 mg and emtricitabine 200 mg), as preexposure prophylaxis (PrEP), to reduce the risk of acquiring HIV-1 in adult men who have sex with men (MSM), heterosexually active men and women, and injection drug users who are at substantial risk of HIV acquisition.[20,22] Patients must be tested for HIV at baseline and minimally every 3 months while taking PrEP. STI testing should occur every 3 to 6 months for patients taking PrEP. Additionally, due to the potential toxicities associated with TDF, renal function must be assessed at baseline and at 6-month intervals in patients taking (Truvada) as PrEP. Patient counseling including stressing the importance of medication adherence should be routinely provided as medication adherence has been linked to PrEP efficacy.[22] In 2019, the FDA approved Tenofovir alafenamide + emtricitabine (Descovy) is for PrEP in at-risk adults and adolescents weighing at least 35 kg, except in individuals at risk from receptive vaginal sex.

OUTCOME EVALUATION

KEY CONCEPT The success of ART is measured by the degree to which the therapy (a) restores and preserves immunologic function, (b) maximally and durably suppresses plasma HIV RNA, (c) improves quality of life, (d) reduces HIV-related morbidity and mortality, and (e) prevents opportunistic infections. **KEY CONCEPT** The major outcome parameters are plasma HIV RNA, CD4 T-lymphocyte absolute count, and percentage. Adequate virologic response in antiretroviral naïve patients is a 1-log decrease in plasma HIV RNA by 2 to 8 weeks after starting medications, followed by concentrations less than 50 copies/mL (50 × 10^3 copies/L) by 12 to 16 weeks based upon the assay available (if plasma HIV RNA < 100,000/mL [100 × 10^6/L] or by 16–24 weeks if plasma HIV RNA > 100,000/mL [100 × 10^6/L]). An immunologic response in antiretroviral naïve patients consists of an increase in CD4 cell count that averages 50 to 150 cells/mm^3 (50 × 10^6–150 × 10^6/L) during the first year of cART (with a faster response in the first 3 months). Virologic failure is defined as the inability to obtain or maintain a plasma HIV RNA less than 200 copies/mL (200 × 103 copies/L), whereas incomplete virologic response is defined as two consecutive plasma HIV RNA greater than 200 copies/mL (200 × 103 copies/L) after 24 weeks of therapy.

Upon initiating or changing ART, plasma HIV RNA should be measured after 2 to 8 weeks and every 4 to 8 weeks until undetectable. Once the viral load is stable (eg, undetectable), plasma HIV RNA is monitored generally every 3 to 6 months. In highly treatment-experienced patients, adequate immunologic response may be only a stable, or slightly increased, CD4$^+$ count and a stable HIV RNA. This may be enough to prevent clinical progression. However, with new agents available for treatment-experienced patients, the goal of treatment should be to reestablish maximal viral suppression to less than 20 to 75 plasma HIV RNA copies/mL (20–75 × 10^3 copies/L), depending on the assay used.[9]

There should be a plan for each patient to assess the effectiveness of ART after initiation. Patients should have follow-up within the first week after initiating a new drug regimen. At each clinic visit, patients should be evaluated for the presence of adverse drug reactions, drug allergies, medication adherence, and potential drug interactions. Antiretrovirals have both class-associated and drug-specific adverse effects (see Tables 87–5 and Table 87–6). If the patient experiences any of the serious, life-threatening effects (Table 87–8), the offending agent should be discontinued promptly, and in most cases, the patient cannot be rechallenged. Potential long-term complications that may reduce the quality of life are listed in Table 87–9. If the patient does not tolerate a medication despite efforts to minimize or eliminate barriers to adherence, consider changing the drug.[9]

KEY CONCEPT Treatment of HIV is lifelong. Unplanned short-term treatment interruptions may be necessary due to illness that precludes administration of oral therapy. If a patient must interrupt therapy due to illness, all drugs of the regimen should be stopped at the same time, regardless of half-life. The strategy of scheduling elective treatment interruptions (where patients stop and start ART based on CD4$^+$ T-cell count criteria) has been evaluated in several clinical trials. Viral rebound occurs quickly after stopping therapy and worsens immune function, causes clinical progression, and may even result in death. More information about treatment interruption can be found in the 2021 DHHS Guidelines.[9]

Table 87–8

Serious Adverse Effects and Management

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Hepatotoxicity	Efavirenz, nevirapine, PIs, most NRTIs, dolutegravir in patients with HBC/HCV coinfection and MVC	**Onset:** NNRTI—60% within first 12 weeks PI—weeks to months NRTI—months to years **Symptoms:** NNRTI—asymptomatic to nonspecific symptoms, such as anorexia, weight loss, or fatigue PI—generally asymptomatic, some with anorexia, weight loss, jaundice NRTI—zidovudine, didanosine, stavudine may cause hepatotoxicity associated with lactic acidosis; lamivudine, emtricitabine, or tenofovir may cause HBV flare when these drugs are withdrawn Dolutegravir: asymptomatic, some with jaundice	HBV or HCV coinfection Alcoholism Concomitant hepatotoxic drugs	Monitor LFTs at least every 3–4 months	Rule out other causes. For symptomatic patients: D/C all antiretrovirals and other potential hepatotoxic agents; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents). For asymptomatic patients: If ALT > 5–10 × ULN, may consider D/C antiretrovirals or continue with close monitoring; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents)
Lactic acidosis/hepatic steatosis ± pancreatitis	NRTIs (esp. stavudine, didanosine, zidovudine)	**Onset:** Months after initiation **Symptoms:** Nonspecific GI (nausea, anorexia, abdominal pain, vomiting, weight loss, fatigue) Laboratory values: ↑ lactate, ↓ arterial pH, ↓ serum bicarbonate, ↑ AST/ALT, ↑ PT, ↑ T.bili, ↓ serum albumin, ↑ amylase/lipase (with pancreatitis)	Stavudine + didanosine Female sex Obesity Pregnancy Didanosine + hydroxyurea or ribavirin ↑ Duration of NRTI use	None unless symptoms present Consider lactate concentrations in patients with ↓ serum bicarbonate or ↑ anion gap	D/C all antiretrovirals; symptomatic support with fluids; some patients require IV bicarbonate, hemodialysis, parenteral nutrition, or mechanical ventilation; once syndrome resolves, consider using NRTIs with ↓ mitochondrial toxicity (abacavir, tenofovir, lamivudine, or emtricitabine); monitor lactate after restarting NRTIs; some clinicians use NRTI-sparing regimens
Stevens–Johnson syndrome/toxic epidermal necrosis	Nevirapine > efavirenz, delavirdine, etravirine; also, amprenavir, abacavir, zidovudine, didanosine, indinavir lopinavir/r, atazanavir, darunavir, rilpivirine, raltegravir	**Onset:** First day–weeks after therapy start **Symptoms:** Skin eruption with mucosal ulcerations; fever, tachycardia, malaise, myalgia, arthralgia; for nevirapine may also have hepatic toxicity	Nevirapine—female, Black, Asian, Hispanic	Nevirapine: use 2-week lead in 200 mg daily, then 200 mg twice a day Avoid corticosteroid use during dose escalation—may increase rash incidence Educate patients to report symptoms as soon as they appear	D/C all antiretrovirals as well as any other possible cause; aggressive symptom support; do not rechallenge patient with offending agent; if caused by nevirapine, avoid NNRTI class, if possible

Hypersensitivity reaction (HSR)	Abacavir	**Onset:** Median = 9 days; 90% within first 6 weeks **Symptoms:** Acute onset of symptoms (most frequent to least): high fever, diffuse skin rash, malaise, nausea, headache, myalgia, chills, diarrhea, vomiting, abdominal pain, dyspnea, arthralgia, respiratory symptoms	HLA-B*5701, HLA-DR7, HLA-DQ3 Antiretroviral-naïve patients Higher incidence with 600 mg every day compared with twice a day dosing	HLA-B*5701 screening prior to abacavir if (+), label as abacavir allergic in medical chart Educate patients about signs and symptoms of HSR and the need of a prompt report	D/C abacavir and other antiretrovirals; rule out other causes of symptoms, most signs and symptoms resolve 48 hours after abacavir/D/C; do not rechallenge with abacavir after suspected HSR
Bone marrow suppression	Zidovudine	**Onset:** Few weeks–months **Symptoms:** Fatigue, risk of ↑ bacterial infections due to neutropenia; anemia, neutropenia	Advanced HIV High-dose zidovudine Preexisting anemia or neutropenia Concomitant use of bone marrow suppressants	Avoid in patients at high risk for bone marrow suppression; avoid other suppressing agents; monitor CBC with differential at least every 3 months	Switch to another NRTI; D/C concomitant bone marrow suppressant, if possible; for anemia: identify and treat other causes; consider erythropoietin treatment or blood transfusion, if indicated; for neutropenia: Identify and treat other causes; consider filgrastim treatment, if indicated
Nephrotoxicity	Tenofovir disoproxil fumarate. Switching from TDF to TAF is associated with improvement in proteinuria and renal biomarkers	**Onset:** Tenofovir—weeks to months after therapy **Symptoms:** Tenofovir disoproxil fumarate—asymptomatic to symptoms of nephrogenic diabetes insipidus, Fanconi syndrome; ↑ serum creatinine, proteinuria, hypophosphatemia, glycosuria, hypokalemia, nonanion gap metabolic acidosis	History of renal disease Concomitant use of nephrotoxic drugs	Avoid use of other nephrotoxic drugs; adequate hydration if on indinavir; monitor creatinine, urinalysis, serum potassium and phosphorus in patients at risk	D/C offending agent, generally reversible; supportive care; electrolyte replacement as indicated

ALT, alanine aminotransferase; AST, aspartate aminotransferase; CBC, complete blood cell count; CPK, creatine phosphokinase; D/C, discontinue; HBV, hepatitis B virus; HCV, hepatitis C virus; LFT, liver function tests; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside/nucleotide reverse transcriptase inhibitor; PI, protease inhibitor; PT, prothrombin time; T.bili, total bilirubin; ULN, upper limit of normal.

Table 87–9

Other Adverse Effects and Management

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Potential Long-Term Complications					
Cardiovascular	Potentially all PIs and other antiretrovirals (efavirenz, stavudine—unfavorable lipid effect; abacavir, didanosine—unknown)	**Onset:** months to years after therapy initiation **Symptoms:** premature CVD	Other risk factors for CVD	Consider non–PI-based regimen; lifestyle modification, counseling	Early diagnosis, prevention, and pharmacologic therapy for hyperlipidemia, HTN, insulin-resistance/diabetes mellitus; assess cardiac risk factors; switch to NNRTI- or atazanavir-based regimen; avoid stavudine
Hyperlipidemia	All PIs (except atazanavir); stavudine; efavirenz (to a lesser extent) Tenofovir alafenamide	**Onset:** weeks to months after therapy initiation **Symptoms:** all PIs except atazanavir—↑ LDL and total cholesterol (TC), ↑↓ HDL; lopinavir/ritonavir and ritonavir—disproportionate ↑ TG; stavudine—↑ TG; may also ↑ LDL and TC; efavirenz or nevirapine—↑ HDL, slight ↑ TG Tenofovir alafenamide: ↑ TG, ↑ LDL, ↑ HDL	Underlying hyperlipidemia PI: Tipranavir/r > lopinavir/r and ritonavir > nelfinavir and amprenavir > indinavir and saquinavir > atazanavir NNRTI: < PIs; efavirenz > nevirapine, etravirine, or rilpivirine NRTI: stavudine > zidovudine and tenofovir most common	Use non-PI, non–stavudine-based regimens; use atazanavir-based regimen; monitor fasting lipid profile at baseline, 3–6 months after new regimen, then at least annually	Assess cardiac risk factor; lifestyle modification; switch to antiretrovirals with fewer lipid effects; consider statin therapy
Insulin resistance/ diabetes mellitus	All PIs	**Onset:** weeks to months after therapy initiation **Symptoms:** polyuria, polydipsia, polyphagia, fatigue, weakness; exacerbation of hyperglycemia in patients with underlying diabetes	Underlying hyperglycemia, family history of diabetes mellitus	Use PI-sparing regimens; monitor fasting blood glucose 1–3 months after starting new regimen, then at least every 3–6 months	Diet and exercise; consider switching to an NNRTI-based regimen; if need for pharmacologic therapy, consider metformin, sulfonylurea, "glitazones," or insulin, where indicated
Osteoporosis/ Osteonecrosis	All ARTs, Tenofovir disoproxil fumarate. TDF has been shown to lead to 1%–3% greater bone mineral density loss compared to other NRTIs	**Onset:** insidious **Symptoms:** mild-to-moderate periarticular pain; 85% of cases involve one or both femoral heads	Diabetes Prior steroid use Advanced age Alcohol use Hyperlipidemia	Risk reduction (limit steroid and alcohol use): for asymptomatic cases with < 15% bony head involvement, monitor with MRI every 3–6 months × 1 year, then every 6 months × 1 year, then annually	Conservative: reduce weight-bearing activity on affected joint; reduce risk factors; analgesics as needed; surgical: core decompression ± bone grafting (early disease); total joint arthroplasty (severe disease)
Quality-of-Life Complications					
CNS effects	Efavirenz, Doravirine, all INSTIs	**Onset:** first few doses **Symptoms:** one or more of the following: drowsiness, insomnia, abnormal dreams, dizziness, impaired concentration, depression, hallucination; exacerbation of psychiatric disorders; psychosis; suicidal ideation	Preexisting or unstable psychiatric illness Use of other drugs with CNS effects May be more common in African Americans due to genetic predisposition of ↓ clearance	Take no earlier than 2–3 hours before bedtime; take on an empty stomach; counsel patients to avoid operating machinery during first 2–4 weeks of therapy	Symptoms usually diminish or resolve after 2–4 weeks; may consider discontinuing therapy if symptoms persist and significantly impair daily function or exacerbate psychiatric illness

Fat maldistribution	PIs, thymidine analogs (stavudine more common than zidovudine)	**Onset:** gradually, months after therapy initiation **Symptoms:** lipoatrophy—peripheral fat loss (facial thinning, thinning of extremities and buttocks); lipohypertrophy—increase in abdominal girth, breast size, and dorsocervical fat pad (buffalo hump)	Lipoatrophy—low baseline body mass index	DEXA scan; lipoatrophy: avoid thymidine analogs or switch from zidovudine or stavudine to abacavir or tenofovir	Switching to other agents may slow or stop progression, but may not reverse effects; injectable poly-L-lactic acid for facial lipoatrophy, human growth hormone
GI intolerance	All PIs, zidovudine, Elvitegravir/cobicistat, Ibalizumab	**Onset:** first few doses **Symptoms:** nausea, vomiting, abdominal pain; diarrhea commonly seen with nelfinavir, lopinavir/ritonavir, and didanosine-buffered formulations	All patients	Taking with food may reduce symptoms (not for ibalizumab); may preemptively need antiemetics or antidiarrheals	May spontaneously resolve or become tolerable with time; nausea and vomiting: consider antiemetic prior to dosing; switch to less emetogenic agent; diarrhea: consider antimotility agents, calcium tablets, bulk-forming agents, and/or pancreatic enzymes
Injection site reactions	Enfuvirtide	**Onset:** first new doses **Symptoms:** pain, pruritus, erythema, ecchymosis, warmth, nodules, rarely injection site infection	All patients	Educate regarding use of sterile technique, solution at room temperature, rotation of injection sites, avoidance of sites with little subcutaneous fat or existing reactions	Massaging the area vigorously before and after injection may reduce pain; wear loose clothing around injection-site areas; take warm shower or bath prior to injection; rarely, warm compact or analgesics may be necessary

ART, antiretroviral; CVD, cardiovascular disease; D/C, discontinue; DEXA, dual-energy X-ray absorptiometry; GI, gastrointestinal; HTN, hypertension; INSTI, integrase inhibitor; LDL, low-density lipoprotein; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside/nucleotide reverse transcriptase inhibitor; PI, protease inhibitor; TG, triglyceride.

Patient Care Process: Newly Diagnosed

Collect Information:

- Confirm HIV infection, screen for additional sexually transmitted infections, and assess the risk for opportunistic infections and need for prophylaxis.
- Create a safe and comfortable environment to obtain a thorough medical and medication history (prescription, nonprescription, and natural drug product use). Review and update patient allergies.
- Acquire baseline laboratory data (see Table 87–1) to stage HIV disease and to assist in the selection of cART drug regimens (genotypic resistance testing, HLA-B*5701).

Assess the Information:

- Assess patient's readiness for initiating cART.
- Evaluate comorbid conditions (eg, mental illness, substance abuse) and social issues (economic stability, lack of social support, insurance coverage) that may impair medication adherence.
- Assess the potential for clinically significant drug–drug, drug–food, drug–disease interactions.

Develop a Care Plan:

- Utilize results of genotype in conjunction with patient-specific factors to construct a recommended cART regimen.

Implement the Care Plan:

- Provide patient with basic information regarding HIV infection, progression of HIV/prognosis, treatment options, and support services available.
- Inform patient of the benefits of initiating cART, stressing the importance of 100% medication adherence.
- Educate patient on regimen-specific administration and common adverse drug effects (see Table 87–5). Warn patient of the key signs and symptoms of severe toxicity (i.e., jaundice and abacavir hypersensitivity reaction [HSR]).
- Provide risk reduction counseling on effective strategies to prevent HIV transmission and disclosure to sexual and/or needle-sharing partners.

Follow-up: Monitor and Evaluate:

- Assess response to cART therapy by drawing plasma HIV RNA within 2 to 4 weeks (no later than 8 weeks) after initiation of cART and every 4 to 8 weeks until plasma HIV RNA is suppressed.
- Monitor immune reconstitution by measuring CD4 count 3 months after initiation of cART.
- Evaluate tolerability of regimen by assessing for adverse events and medication adherence.
- Ensure continued coordination of care and management of mental and psychosocial determinants of health

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
ALT	Alanine aminotransferase
ART	Antiretroviral therapy
AST	Aspartate aminotransferase
cART	Combination antiretroviral therapy
CPK	Creatine phosphokinase
CVD	Cardiovascular disease
CYP	Cytochrome P-450 isoenzyme
D/C	Discontinue
DEXA	Dual-energy X-ray absorptiometry
DHHS	Department of Health and Human Services
DNA	Deoxyribonucleic acid
ELISA	Enzyme-linked immunosorbent assay
FDA	Food and Drug Administration
GERD	Gastroesophageal reflux disease
Gp	Glycoprotein
HAART	Highly active antiretroviral therapy
HBeAg	Hepatitis B early antigen
HBV	Hepatitis B virus
HCV	Hepatitis C virus
HDL	High-density lipoprotein
HIV	Human immunodeficiency virus
HLA	Human leukocyte antigen
HSR	Hypersensitivity reaction
HTN	Hypertension
IAS-USA	International Antiviral Society–USA
INSTI	Integrase strand transfer inhibitor
LDL	Low-density lipoprotein
LFTs	Liver function tests
MSM	Men who have sex with men
MTCT	Mother-to-child transmission
NAT	Nucleic acid test
NNRTI	Nonnucleoside reverse transcriptase inhibitor
NRTI	nucleoside/nucleotide reverse transcriptase inhibitor
NtRTI	Nucleotide reverse transcriptase inhibitor
P-gp	P-glycoprotein
PCP	*Pneumocystis jiroveci* (formerly *carinii*) pneumonia
PI	Protease inhibitor
PrEP	Preexposure prophylaxis
PT	Prothrombin time
RNA	Ribonucleic acid
RT-PCR	Reverse transcriptase polymerase chain reaction
STI	Sexually transmitted disease
STI	Sexually transmitted infection
T.bili	Total bilirubin
TDF	Tenofovir disoproxil fumarate
TG	Triglyceride
ULN	Upper limit of normal

Cancer Principles and Therapeutics

Lisa M. Holle

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the etiology of cancer.
2. Define the tumor, nodes, metastases (TNM) system of cancer staging.
3. Classify each drug used in the treatment of cancer and compare and contrast the mechanisms of action, uses, and adverse effects.
4. Outline actions for all healthcare professionals to prevent medication errors with cancer treatments.
5. Describe what cancer survivorship means and how this impacts future healthcare needs of an individual.

INTRODUCTION

KEY CONCEPT The word cancer covers a diverse array of tumor types that affect a significant number of Americans and individuals worldwide and are a major cause of mortality. The term cancer actually refers to more than 100 different diseases. What is common to all cancers is that the cancerous cell is uncontrollably growing and has the potential for invading local tissue and spreading to other parts of the body, a process called metastases. Cancer is the second leading cause of death behind heart disease.[1] In 2021, it was projected that nearly 1.9 million Americans will be diagnosed with cancer, and that an estimated 608,570 Americans will die from cancer.[1] Figure 88–1 describes cancers by gender, new cases, and deaths.

Once diagnosed, a cancer patient may encounter many different healthcare professionals. All healthcare professionals must collaborate to ensure safe and appropriate prescribing, preparation, administration, and monitoring of anticancer agents; management of toxicities; resolution of reimbursement issues; and participation in clinical trials. The pharmacist is a pivotal member of the care team because of their medication expertise.[2,3]

As a result of advances in research and technology, available cancer treatments have increased dramatically in the last couple of decades. The fields of radiation therapy, surgery, and drug development have made enormous progress over the years. Therefore, patients are often receiving treatments that are less toxic and with better treatment outcomes than in the past. Supportive care therapies have also improved, and patients now may be at less risk for toxicity and have a better quality of life than patients in the past. Twenty years ago, most patients received chemotherapy in the hospital because of side effects. Today, many more patients are able to receive chemotherapy in outpatient clinics and/or take oral anticancer agents at home.

Cancer Prevention

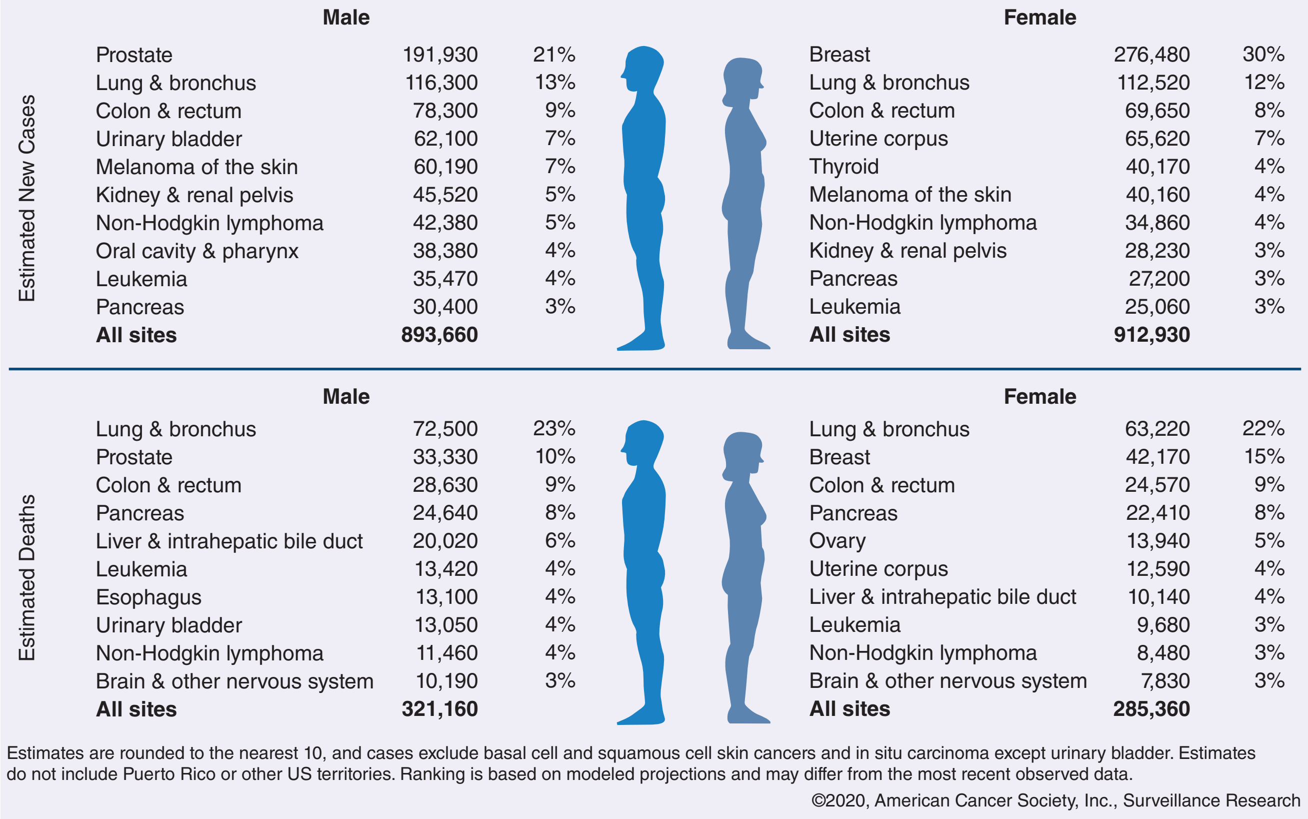
Because most cancers are not curable in advanced stages, cancer prevention is an important and active area of research. Both lifestyle modifications and chemoprevention agents may significantly reduce the risk of developing some cancers. An active area of investigation, The Food and Drug Administration (FDA) has approved vaccines that can help prevent cancer. Available vaccines include those that prevent infection with human papillomavirus (HPV), responsible for many cancers of the cervix, vulva, vagina, and anus and a vaccine that prevents hepatitis B viral infections, which can cause liver cancer. Additionally, orally administered medications, such as the selective estrogen receptor (ER) modulator (SERM) tamoxifen, reduces the risk of breast cancer in premenopausal women. Another SERM, raloxifene and the aromatase inhibitor (AI) exemestane both have shown a reduction in breast cancer in high-risk postmenopausal women. Because these agents will have adverse effects and possible long-term complications (eg, an increased risk of endometrial cancer with the use of tamoxifen), benefits versus risks needs to be weighed when initiating these breast cancer prevention strategies.

Tobacco

Tobacco smoking increases the risk of developing not only lung cancer but also many other types of cancer, including cancer of the bladder, mouth, pharynx, larynx, and esophagus as well as kidney cancer. Smoking cessation is associated with a gradual decrease in the risk of cancer, but more than 5 years is needed before a major decline in risk is detected. In addition, most studies have found that passive smoking (ie, secondhand smoke) also increases a person's risk of developing lung cancer.[4]

Ultraviolet Radiation

Ultraviolet light (sunlight or tanning booths and lamps) exposure may increase the risk of developing melanoma and other skin cancers, especially in individuals who have a positive family history, fair skin, light-colored eyes, high degrees of freckling, and a tendency to burn instead of tan. Practitioners can counsel patients on proper sun protection, including minimizing sun exposure, using sunscreens with a sun protection factor (SPF) of 15 or greater on exposed areas (along with proper reapplication), wearing protective clothing and sunglasses, avoiding tanning beds and sun lamps, and the importance of early detection.



Estimated New Cases

Male			Female		
Prostate	191,930	21%	Breast	276,480	30%
Lung & bronchus	116,300	13%	Lung & bronchus	112,520	12%
Colon & rectum	78,300	9%	Colon & rectum	69,650	8%
Urinary bladder	62,100	7%	Uterine corpus	65,620	7%
Melanoma of the skin	60,190	7%	Thyroid	40,170	4%
Kidney & renal pelvis	45,520	5%	Melanoma of the skin	40,160	4%
Non-Hodgkin lymphoma	42,380	5%	Non-Hodgkin lymphoma	34,860	4%
Oral cavity & pharynx	38,380	4%	Kidney & renal pelvis	28,230	3%
Leukemia	35,470	4%	Pancreas	27,200	3%
Pancreas	30,400	3%	Leukemia	25,060	3%
All sites	**893,660**		**All sites**	**912,930**	

Estimated Deaths

Male			Female		
Lung & bronchus	72,500	23%	Lung & bronchus	63,220	22%
Prostate	33,330	10%	Breast	42,170	15%
Colon & rectum	28,630	9%	Colon & rectum	24,570	9%
Pancreas	24,640	8%	Pancreas	22,410	8%
Liver & intrahepatic bile duct	20,020	6%	Ovary	13,940	5%
Leukemia	13,420	4%	Uterine corpus	12,590	4%
Esophagus	13,100	4%	Liver & intrahepatic bile duct	10,140	4%
Urinary bladder	13,050	4%	Leukemia	9,680	3%
Non-Hodgkin lymphoma	11,460	4%	Non-Hodgkin lymphoma	8,480	3%
Brain & other nervous system	10,190	3%	Brain & other nervous system	7,830	3%
All sites	**321,160**		**All sites**	**285,360**	

Estimates are rounded to the nearest 10, and cases exclude basal cell and squamous cell skin cancers and in situ carcinoma except urinary bladder. Estimates do not include Puerto Rico or other US territories. Ranking is based on modeled projections and may differ from the most recent observed data.

CARCINOGENESIS

The exact cause of cancer remains unknown and is probably very diverse given the vast array of diseases called cancer. It is thought that cancer develops from a single cell in which the normal mechanisms for control of growth and proliferation are altered. Current evidence indicates that there are four stages in the cancer development process. The first step, **initiation**, occurs when a carcinogenic substance encounters a normal cell to produce genetic damage and results in a mutated cell. The environment is altered by carcinogens or other factors to favor the growth of the mutated cell over the normal cell during **promotion**, the second step. The main difference between initiation and promotion is that promotion is a reversible process. Third, **transformation** (or **conversion**) occurs when the mutated cell becomes malignant. Depending on the type of cancer, many years may elapse between the carcinogenic phases and the development of a clinically detectable tumor. Finally, **progression** occurs when cell proliferation takes over and the tumor spreads or develops metastases.

There are substances known to have carcinogenic risks, including chemicals, environmental factors, and viruses. Chemicals in the environment, such as aniline and benzene, are associated with the development of bladder cancer and leukemia, respectively. Environmental factors, such as excessive sun exposure, can result in skin cancer, and smoking is widely known as a cause of lung cancer. Viruses, including HPV, Epstein-Barr virus, and hepatitis B virus, have been linked to cervical cancers, lymphomas, and liver cancers, respectively. Anticancer agents such as the alkylating agents (eg, melphalan), anthracyclines (eg, doxorubicin), epipodophyllotoxins (eg, etoposide), and poly ADP ribose polymerase (PARP) inhibitors (eg, olaparib) can cause secondary malignancies (eg, leukemias) years after therapy has been completed. Additionally, factors such as the patient's age, gender, family history, diet, and chronic irritation or inflammation may be considered to be promoters of carcinogenesis.

Cancer Genetics

Because the human genome has been sequenced and with the great improvements in genetic technology, growing knowledge regarding the genetic changes of cancer exist. Two major classes of genes are involved in carcinogenesis: **oncogenes** and **tumor suppressor genes**. **Proto-oncogenes** are normal genes that, through some genetic alteration caused by carcinogens, change into oncogenes. Proto-oncogenes are present in all normal cells and regulate cell function and replication. Genetic damage of the proto-oncogene may occur through point mutation, chromosomal rearrangement, or an increase in gene function, resulting in the oncogene. The genetic damage may either be inherited from an individual's parents (germline mutations) or by way of carcinogenic agents (eg, smoking). The oncogene produces abnormal or excessive gene product that disrupts normal cell growth and proliferation.[5] As a result, this may cause the cell to have a distinct growth advantage, increasing its likelihood of becoming cancerous. Table 88–1 provides examples of oncogenes by their cellular function and associated cancer.[6]

Table 88–1

Examples of Oncogenes and Tumor Suppressor Genes

Gene	Function	Associated Human Cancer
Oncogenes		
Genes for growth factors or their receptors		
EGFR? ERBB1	Codes for epidermal growth factor (EGFR) receptor	Glioblastoma, breast, head and neck, and colon cancers
HER2/ERBB2	Codes for a growth factor receptor	Breast, salivary gland, prostate, bladder, and ovarian cancers
RET	Codes for a growth factor receptor	Thyroid cancer
Genes for cytoplasmic relays in stimulatory signaling pathways		
KRAS and NRAS	Code for guanine nucleotide-proteins with GTPase activity	Lung, ovarian, colon, pancreatic cancers Neuroblastoma, acute leukemia
Genes for transcription factors that activate growth-promoting genes		
cMYC	Codes for transcription factor	Leukemia and breast, colon, gastric, and lung cancers
NMYC	Codes for transcription factor	Neuroblastoma, small cell lung cancer, and glioblastoma
Genes for cytoplasmic kinases		
BCR-ABL	Codes for a nonreceptor tyrosine kinase	Chronic myelogenous leukemia
ALK	Receptor tyrosine kinase	Lung cancer, lymphomas, neuroblastoma, and ovarian cancer
BRAF	Serine-threonine protein kinase	Colon cancer, lung cancer, melanoma, ovarian, thyroid cancer
KIT (CD117)	Receptor tyrosine kinase	Acute Leukemia, gastrointestinal, stromal tumor, and gastrointestinal stromal tumor
PIK2CA	Lipid kinases	Lung cancer, ovarian cancer
RET	Codes a receptor tyrosine kinase	Lung cancer, thyroid cancer
Genes for other molecules		
BCL2	Codes for a protein that blocks apoptosis	Indolent B-cell lymphomas
BCL1/PRAD1	Codes for cyclin D_1, a cell-cycle clock stimulator	Breast, head, and neck cancers
MDM2	Protein antagonist of p53 tumor suppressor protein	Sarcomas
Tumor-Suppressor Genes		
Genes for proteins in the cytoplasm		
APC	Step in a signaling pathway	Colon and gastric cancer
NF1	Codes for a protein that inhibits the stimulatory Ras protein	Neurofibroma, leukemia, and pheochromocytoma
NF2	Codes for a protein that inhibits the stimulatory Ras protein	Meningioma, ependymoma, and schwannoma
Genes for proteins in the nucleus		
MTS1	Codes for p16 protein, a cyclin-dependent kinase inhibitor	Involved in a wide range of cancers
RB1	Codes for the pRB protein, a master brake of the cell cycle	Retinoblastoma, osteosarcoma, and bladder, small cell lung, prostate, and breast cancers
TP53	Codes for the p53 protein, which can halt cell division and induce apoptosis	Involved in a wide range of cancers
PTEN	Phosphatase and tensin homolog deleted on chromosome ten	Lung cancer, ovarian cancer
Genes for protein whose cellular location is unclear		
BRCA1	DNA repair, transcriptional regulation	Breast and ovarian cancers
BRCA2	DNA repair	Breast cancer
VHL	Regulator of protein stability	Kidney cancer
MSH2, MLH1, PMS1, PMS2, MSH6	DNA mismatch repair enzymes	Hereditary nonpolyposis colorectal cancer

From Cordes LM, Shord SS. Cancer treatment and chemotherapy. In: DiPiro JT, Yee GC, Posey LM, et al. eds. Pharmacotherapy: A Pathophysiologic Approach, 11th ed. New York, NY: McGraw-Hill; 2020: Table 144–2.

Tumor suppressor genes inhibit inappropriate cellular growth and proliferation. When gene loss or mutation occurs, this results in a loss of control over normal cell growth. The *TP53* gene is one of the most common tumor suppressor genes, and mutations of *TP53* may occur in up to 50% of all malignancies. This gene stops the cell cycle to enable "repair" of the cell. If *TP53* is inactivated, then the cell allows the mutations to occur. Although mutations of the *TP53* gene are found in many tumors, such as breast, colon, and lung cancer, it is also associated with drug resistance of cancer cells. Deoxyribonucleic acid (DNA) repair genes fix errors in DNA that occur because of environmental factors or errors in replication and can be classified as tumor suppressor genes. Mutations in DNA repair genes have been reported in hereditary nonpolyposis colon cancer and in some breast cancer syndromes.

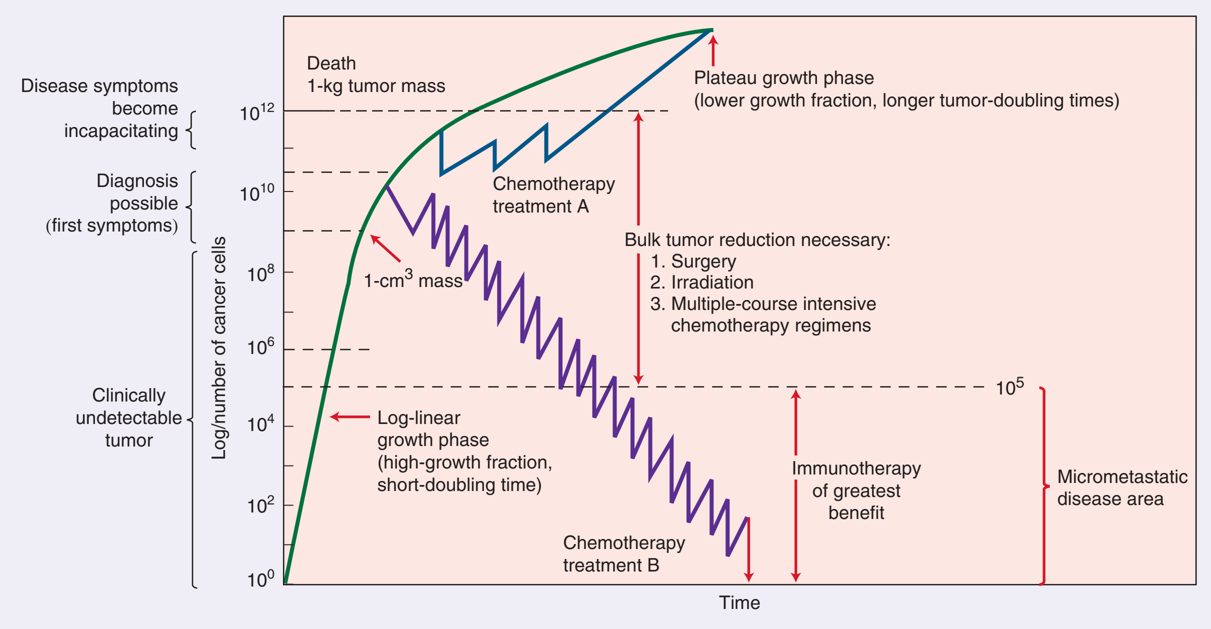

FIGURE 88–2. The Gompertzian growth curve demonstrating symptoms and treatments versus tumor volume.

KEY CONCEPT Numerous cellular changes occur in the genetic material of the cancer cell so that programmed cell death (PD), or apoptosis, does not occur. Proliferation of cancer cells goes unregulated. If mutations persist and cells are not repaired or suppressed, cancer may develop. Apoptosis, or PD, may prevent the mutated cell from becoming cancerous. Loss of *TP53* and overexpression of B-cell lymphoma 2 (*BCL2*) are two examples of changes within the cell that occur to result in enhanced cell survival.

Identification of genes involved in cancer may be conducted for various reasons, including cancer screening to determine if an individual is at an increased risk of cancer, to develop new anticancer agents, to aid in diagnosis, and to predict response and/or the toxicity of the agents used in individual patients.

Principles of Tumor Growth

It takes about 10^9 cancer cells to be clinically detectable by palpation or radiography. Figure 88–2 demonstrates the classic Gompertzian kinetics tumor growth cycle. From the diagram, one can see that malignant cell growth occurs many times before a mass may be detected. The number of malignant cells may decrease drastically because of surgery or in decreasing steps by each administration of chemotherapy. One dosing round, or cycle, of chemotherapy does not eliminate all malignant cells; therefore, repeated cycles of chemotherapy are administered to eliminate tumor cell burden. The cell kill hypothesis states that a fixed percentage of tumor cells will be killed with each cycle of chemotherapy. According to this hypothesis, the number of tumor cells will never reach zero. This theory assumes that all cancers are equally responsive and that anticancer drug resistance and metastases do not occur, which is not the case.[7]

Metastases

A metastasis is a growth of the same cancer cell found at some distance from the primary tumor site.[8] The metastasis may be large, or it may be just a few cells that may be detected through polymerase chain reaction (PCR); however, the presence of metastasis at diagnosis usually is associated with a poorer prognosis than a patient with no known metastatic disease. As the technology to detect malignant cells evolves, the dilemma exists on how to treat patients based on current guidelines that were not based on cellular detection technology.

Cancers spread usually by two pathways: hematogenous (through the bloodstream) or through the lymphatics (drainage through adjacent lymph nodes). The malignant cells that split from the primary tumor find a suitable environment for growth. It is believed that malignant cells secrete mediators that stimulate the formation of blood vessels for growth and oxygen, the process of angiogenesis. Common metastatic sites for solid tumors include the brain, bone, lung, and liver.

PATHOPHYSIOLOGY

Tumor Origin

Tumors may arise from any of four basic tissue types: epithelial, connective (ie, muscle, bone, and cartilage), lymphoid, or nerve tissue. The suffix *-oma* is added to the name of the cell type if the tumor cells are benign. A *lipoma* is a benign growth that resembles fat tissue.

Precancerous cells have cellular changes that are abnormal but not yet malignant and may be described as *hyperplastic* or *dysplastic*. Hyperplasia occurs when a stimulus is introduced and reverses when the stimulus is removed. Dysplasia is an abnormal change in the size, shape, or organization of cells or tissues.

Malignant cells are divided into categories based on the cells of origin. Carcinomas arise from epithelial cells, whereas sarcomas arise from muscle or connective tissue. Adenocarcinomas arise from glandular tissue. *Carcinoma* in situ refers to cells limited to epithelial origin that have not yet invaded the basement membrane. Malignancies of the bone marrow or lymphoid tissue, such as leukemias or lymphomas, are named differently.

Tumor Characteristics

Tumors are either benign or malignant. Benign tumors often are encapsulated, localized, and indolent; they seldom metastasize; and they rarely recur once removed. Histologically, the cells resemble the cells from which they developed. Malignant tumors are invasive and spread to other locations even if the primary tumor is removed. The cells no longer perform their usual functions, and their cellular architecture changes. This loss of structure and function is called anaplasia. Despite improvements in screening procedures, many patients have metastatic disease at the time of diagnosis. Usually, once distant metastases have occurred, the cancer is considered incurable.[9]

Patient Encounter 1, Part 1

The patient is a 71-year-old previously healthy man who has had symptoms of fatigue, bright red blood when urinating for 2 weeks and back pain. He has self-treated with over-the-counter (OTC) pain products without relief. Today, he presents to his primary care provider for evaluation. His complete blood count (CBC) reveals a hemoglobin level of 12.6 g/dL and his PSA level is 22.4 ng/dL. He is referred to an urologist for further evaluation.

After a prostate gland biopsy and subsequent computed tomography (CT) and bone scans, a diagnosis of metastatic prostate cancer is made and treatment is planned to start as soon as possible.

What signs and symptoms does this patient have that are consistent with a cancer presentation?

What is your desired outcome when treating this patient?

DIAGNOSIS OF CANCER

Cancer can present as a number of different signs and symptoms. Unfortunately, many people fear a diagnosis of cancer and may not seek medical attention at the first warning signs when the disease is at its most treatable stage. After the initial visit with the clinician, a variety of tests will be performed, which are somewhat dependent on the initial differential diagnoses. Appropriate laboratory tests, radiologic scans, and tissue samples are necessary. The sample of tissue may be obtained by a biopsy, fine-needle aspiration, or exfoliative cytology. No treatment of cancer should be initiated without a pathologic diagnosis of cancer. During the pathologic workup, genetic analysis may be done. Depending on the type of cancer, the genetic analysis can provide the additional information on prognosis of the malignancy and whether certain therapies may be appropriate.

Once the pathology of cancer is established, staging of the disease is done before treatment is initiated. **KEY CONCEPT** The basis of cancer staging is tumor size, extent of lymph node involvement, and the presence or absence of metastases, also referred to as the tumor, nodes, metastases (TNM) system (Table 88–2),[10] and is usually referred to as stages I, II, III, or IV. Not all cancers can be staged according to this system, but many of the solid tumors are. Staging cancer is an important for determing prognosis and guiding treatment decisions.

Some cancers produce substances (eg, proteins) that are detected by a blood test and may be useful in following response to therapy or detecting a recurrence; these are referred to as tumor markers. An example of a clinically used tumor marker is the prostate-specific antigen (PSA). The PSA serum level is used to monitor response to treatment. Unfortunately, some tumor markers are nonspecific and may be elevated from nonmalignant causes. In the case of PSA, nonmalignant causes such as prostatitis, trauma, surgery, ejaculation, some medications, benign prostatic hypertrophy, or riding on an exercise bicycle can all cause increased PSA levels, which needs to be considered when using tumor markers to assess cancer presence of response.[9]

Clinical Presentation and Diagnosis: Cancer Chemotherapy and Treatment

Signs and Symptoms

The seven warning signs of cancer are:

- Change in bowel or bladder habits
- A sore that does not heal
- Unusual bleeding or discharge
- Thickening or lump in breast or elsewhere
- Indigestion or difficulty in swallowing
- Obvious change in a wart or mole
- Nagging cough or hoarseness

The eight warning signs of cancer in children are:

- Continued, unexplained weight loss
- Headaches with vomiting in the morning
- Increased swelling or persistent pain in bones or joints
- Lump or mass in abdomen, neck, or elsewhere
- Development of a whitish appearance in the pupil of the eye
- Recurrent fevers not caused by infections
- Excessive bruising or bleeding
- Noticeable paleness or prolonged tiredness

Diagnostic Procedures

- Laboratory tests: CBC, lactate dehydrogenase (LDH), renal function, and liver function tests
- Radiologic scans: X-rays, CT scans, magnetic resonance imaging (MRI), positron emission tomography (PET)
- Biopsy of tissue or bone marrow with pathologic evaluation
- Cytogenetics
- Tumor markers

Staging determination of the primary tumor size, extent of lymph node involvement, and the presence or absence of metastases, referred to as the TNM system (see Table 88–2). Most solid tumors are staged according to the TNM classification system. The size of the primary tumor, extent of nodal involvement, and the presence of metastases are used to determine the stage. Metastases are cancer cells that have spread to sites distant from the primary tumor site and have started to grow. The most frequently occurring sites of metastases of solid tumors are the brain, bone, liver, and lungs.

Table 88–2

Tumor (T), Node (N), Metastasis (M) Staging for Non–Small Cell Lung Cancer

Primary Tumor		Description
Tx		Primary tumor cannot be assessed or tumor proven by presence of malignant cells in sputum or bronchial washings but not visualized by imaging or bronchoscopy
T0		No evidence of primary tumor
Tis		Carcinoma in situ
T_1	T_{1a} (mi)	Tumor under 3 cm in greatest dimension, surrounded by lung or visceral pleura, without invasion more proximal than lobar bronchus
		Minimally invasive adenocarcinoma
	T_{1a}	Superficial spreading tumor in central airways (spreading tumor of any size but confined to the tracheal or bronchial wall) and tumor ≤ 1 cm in greatest dimension
	T_{1b}	Tumor > 1 cm but ≤ 2 cm in greatest dimension
	T_{1c}	Tumor > 2 cm but ≤ 3 cm in greatest dimension
T_2		Tumor > 3 cm but ≤ 5 cm, or tumor with any of the following features: • Involves main bronchus regardless of distance from the carina but without involvement of the carina • Invades visceral pleura • Associated with atelectasis or obstructive pneumonitis that extends to the hilar region but does not involve the entire lung
	T_{2a}	Tumor > 3 cm but ≤ 4 cm in greatest dimension
	T_{2b}	Tumor > 4 cm but ≤ 5 cm in greatest dimension
T_3		Tumor > 5 cm but ≤ 7 cm in greatest dimension of associated with separate tumor nodule(s) in the same lobe as the primary tumor or directly invades any of the following structures: • chest wall (including the parietal pleura and superior sulcus) • phrenic nerve • parietal pericardium
T_4		Tumor > 7 cm in greatest dimension or associated with separate tumor nodules(s) in a different ipsilateral lobe than that of the primary tumor or invades any of the following structures • diaphragm • mediastinum • heart • great vessels • trachea • recurrent laryngeal nerve • esophagus • vertebral body • carina
Regional lymph nodes (N)		
N_x		Regional lymph nodes cannot be assessed.
N_0		No regional lymph node metastases
N_1		Metastasis in ipsilateral peribronchial and/or ipsilateral hilar lymph nodes and intrapulmonary nodes, including involvement by direct extension
N_2		Metastasis in ipsilateral mediastinal and/or subcarinal lymph node(s)
N_3		Metastasis in contralateral mediastinal, contralateral hilar, ipsilateral or contralateral scalene, or supraclavicular lymph node(s)
Distant metastasis (M)		
M_0		No distant metastasis
M_1		Distant metastasis
	M_{1a}	Separate tumor nodule(s) in a contralateral lobe; tumor with pleural nodules or malignant pleural or pericardial effusion
	M_{1b}	Single extrathoracic metastasis
	M_{1c}	Multiple extrathoracic metastasis in one or more organs

Stage	T	N	M	5-Year Survival (%)
Stage 0	T_{is}	N_0	M_0	
Stage Ia	T_{1a}	N_0	M_0	92
Stage Ib	T_{2a}	N_0	M_0	68
Stage IIa	T_{2b}	N_0	M_0	60
Stage IIb	T_1, T_2	N_1	M_0	53
	T_3	N_0	M_0	
Stage IIIa	T_1, T_2	N_2	M_0	36
	T_3, T_4	N_1	M_0	
	T_4	N_0	M_0	
Stage IIIb	T_1, T_2	N_3	M_0	26
	T_3, T_4	N_2	M_0	
Stage IIIc	T_3, T_4	N_3	M_0	13
Stage IVa	Any T	Any N	M_{1a} or M_{1b}	10
Stage IVb	Any T	Any N	M_{1c}	0

TREATMENT

Desired Outcome

Surgery may be able to remove all macroscopic disease; however, microscopic cells may still be present near the surgical site or may have traveled to other parts of the body. When malignant cells have traveled to other parts of the body and become established there and are able to grow in this new environment, they are called metastatic cancer cells. Thus, for chemotherapy-sensitive diseases, systemic therapies may be administered after surgery to destroy these microscopic malignant cells; this is called **adjuvant chemotherapy**. The goals of adjuvant chemotherapy are to decrease cancer recurrence by eliminating microscopic malignant cells and to prolong survival. Chemotherapy may also be given before surgical resection of the tumor; this is referred to as **neoadjuvant chemotherapy**. Chemotherapy given before surgery should decrease the tumor burden to be removed (which may result in a shorter surgical procedure or less physical disfigurement to the patient) and make the surgery easier to perform because the tumor has shrunk away from vital organs or vessels. Neoadjuvant chemotherapy also gives the clinician an idea of the responsiveness of the tumor to that particular chemotherapy.

Chemotherapy may be given to cure cancers, or it may be given to help control the symptoms of an incurable cancer (also known as palliation). **Palliative care**, however, is used throughout therapy to prevent or treat, as early as possible, the symptoms and side effects of the disease and treatment psychological, social, and spiritual problems. It consists of pharmacologic and nonpharmacologic treatments to improve quality of life and is most effective when initiated at the time of other treatments.[11]

Response

The responses to chemotherapy for solid tumors are described as **complete response (CR)**, **partial response (PR)**, **stable disease (SD)**, or **disease progression**. A cure in oncology implies that the cancer is completely gone, and the patient will have the same life expectancy as a patient without cancer. The response evaluation criteria in solid tumors (RECIST) was developed in 2000 and revised in 2009 and is considered to be the standard criteria to evaluate a response to therapy (Table 88–3).[12] The term **overall objective response rate** refers to all patients with a PR or a CR.

Cancer cells may be **sensitive** to certain chemotherapy agents, but with repeated exposure, the cells may become **resistant** to treatment. The resistant cells then may grow and multiply. In some cancers, a number of genetic mutations, including epidermal growth factor receptor *(EGFR)*, reticular activating system (*RAS*), and *BRAF*, may be used to predict which patients will be sensitive to certain chemotherapy that targets these mutations. These mutations will be discussed in depth in the following cancer-specific chapters.

Nonpharmacologic Therapy

The three primary treatment modalities of cancer are surgery, radiation, and pharmacologic therapy. Surgery is useful to gain tissue for diagnosis of cancer and for treatment, especially those cancers with limited disease. Radiation plays a key role not only in the treatment and possible cure of cancer but also in palliative therapy. Together, surgery and radiation therapy may provide local control of symptoms of the disease. However, when cancer is widespread, surgery may play little or no role, but radiation therapy localized to specific areas may palliate symptoms.

Table 88–3

RECIST 1.1 Criteria: Target Lesion Evaluation

Term	Description
Complete response (CR)	Disappearance of all targeted lesions. All pathological lymph nodes must have decreased to < 10 mm in short axis
Partial response (PR)	At least a 30% decrease in the sum of the longest diameter (SLD) of target lesions from baseline
Progressive disease	SLD increased by at least 20% from the smallest value on study (including baseline, if that is the smallest) The SLD must also demonstrate an absolute increase of at least 5 mm. (Two lesions increasing from 2 to 3 mm, for example, do not qualify)
Stable disease (SD)	Neither sufficient shrinkage to qualify for PR nor sufficient increase to qualify for progressive disease

Adapted from Eisenhauer E, Therasse P, Bogaerts J, et al. New response evaluation criteria in solid tumours: revised RECIST guideline (version 1.1). Eur J Cancer. 2009;45:228–247.

Pharmacologic Therapy

Chemotherapy of cancer started in the early 1940s when nitrogen mustard was first administered to patients with lymphoma. Since then, numerous agents have been developed for the treatment of different cancers.

Dosing of Chemotherapy

Chemotherapeutic agents typically have a very narrow therapeutic index. If too much is administered, the patient may suffer from severe or even fatal toxicities. If too little is given, the desired effect on cancer cells may not be achieved. Many chemotherapy agents have significant organ toxicities that preclude using steadily increasing doses to treat the cancer. The doses of chemotherapy must be given at a frequency that allows the patient to recover from the toxicity of the chemotherapy; each period of chemotherapy dosing is referred to as a cycle. Each cycle of chemotherapy may have the same dosages; the dosages may be modified based on toxicity; or a chemotherapy regimen may alternate from one set of drugs given during the first, third, and fifth cycles to another set of different drugs given during the second, fourth, and sixth cycles. **Dose density** of chemotherapy refers to shortening of the period between cycles of chemotherapy. This can accomplish two things: first, the tumor has less time between cycles of chemotherapy to grow, and second, patients receive the total number of required cycles in a shorter time period. Administration of dose-dense chemotherapy regimens often requires the use of colony-stimulating factors (eg, filgrastim or granulocyte–colony stimulating factor [G-CSF], pegfilgrastim) to be administered. These agents shorten the duration and severity of neutropenia. The chemotherapy regimens that are dose dense tend to be adjuvant regimens, and the goal of therapy is cure. When a chemotherapy regimen is used as *palliation* (to control symptoms), the dosages of chemotherapy may be decreased

Table 88–4

Performance Status Scales

Description: Karnofsky Scale	Karnofsky Scale (%)	Zubrod Scale (ECOG)	Description: ECOG Scale
No complaints; no evidence of disease	100	0	Fully active, able to carry on all predisease activity
Able to carry on normal activity; minor signs or symptoms of disease	90		
Normal activity with effort; some signs or symptoms of disease	80	1	Restricted in strenuous activity but ambulatory and able to carry out work of a light or sedentary nature
Cares for self; unable to carry on normal activity or to do active work	70		
Requires occasional assistance but is able to care for most personal needs	60	2	Out of bed > 50% of time; ambulatory and capable of self-care but unable to carry out any work activities
Requires considerable assistance and frequent medical care	50		
Disabled; requires special care and assistance	40	3	In bed > 50% of time; capable of only limited self-care
Severely disabled; hospitalization indicated, although death not imminent	30		
Very sick; hospitalization necessary; requires active supportive treatment	20	4	Bedridden; cannot carry out any self-care; completely disabled
Moribund; fatal processes progressing rapidly	10		
Dead	0	5	Deceased

ECOG, Eastern Cooperative Oncology Group.

based on toxicity or the interval between cycles may be lengthened to maintain quality of life.

Patient and tumor biology also affect how cancer therapy is dosed. Patients with a uridine diphosphate–glucuronosyltransferase 1A1 enzyme (UGT1A1*28) deficiency can have life-threatening diarrhea and complications from irinotecan related to a decreased ability to metabolize the parent drug. The patient may have a blood test before irinotecan therapy to determine if this genetic mutation is present. In the case of some monoclonal antibodies and targeted agents, flow cytometry results reveal whether the tumor has the receptor where the drug will bind and exert the pharmacologic effect.[13] The therapeutic uses of oncology drugs with valid genomic biomarkers, called targeted therapies, will be discussed briefly in this chapter and in more detail in the following chapters.

Another consideration of chemotherapy administration is the patient. Factors that affect chemotherapy selection and dosing are age, concurrent disease states, and performance status. Performance status can be assessed either with the Eastern Cooperative Oncology Group (ECOG) Scale or the Karnofsky Scale (Table 88–4). Performance status is a very important prognostic factor for many types of cancer. If a patient has renal dysfunction and the chemotherapy is eliminated primarily by the kidney, dosing adjustments will need to be made. If a patient has had a myocardial infarction recently or preexisting heart disease, the clinician will weigh the risks of anthracycline therapy against the benefit of the treatment of the cancer.

Another important consideration for treatment of cancers is insurance coverage for off-label use. Off-label use is when a medication is used to treat a cancer that is not an FDA-approved indication. Because of rapid advancements in oncology, it is estimated that up to 75% of chemotherapy agents are prescribed "off-label." Drugs used according to FDA-approved indications are usually paid for by insurance. If sufficient supportive literature exists and the use is supported by one of the Medicare-approved compendia (eg, AHFS-DI, Clinical Pharmacology, Micromedex DrugDex, and National Comprehensive Cancer Network [NCCN] Compendium), an insurer should cover the cost of the anticancer treatment that does not have an FDA indication.

During the time of chemotherapy administration, patients will likely experience various toxicities. The National Cancer Institute (NCI) has provided a standardized system for evaluating and grading the toxicity from chemotherapy to provide uniform grading of toxicity and evaluation of new agents and regimens (Table 88–5).[14]

Combination Chemotherapy

The underlying principles of using combination therapy are to use (a) agents with different pharmacologic actions, (b) agents with different organ toxicities, (c) agents that are active against the tumor and ideally synergistic when used together, and (d) agents that do not result in significant drug interactions (although these can be studied carefully and the interactions addressed). When two or more agents are used together, the risk of development of resistance may be lessened, but toxicity may be increased.

KEY CONCEPT Traditional chemotherapy agents have some similar side effects, usually manifested on the most rapidly proliferating cells of the body. However, there are unique toxicities of various pharmacologic categories of antineoplastic agents. Anthracyclines (eg, doxorubicin) have the potential to cause cardiac toxicity, which is related to the cumulative dose. Microtubule-targeting agents (eg, vincristine) are associated with various forms of neurotoxicity. Alkylating agents (eg, melphalan) are associated with secondary malignancies.

Currently, anticancer agents are categorized by their mechanism of action. As depicted in Figure 88–3, different agents work in different parts of the cell.[15]

Table 88–5

Selected National Cancer Institute Common Toxicity Criteria

Toxicity	Grade 1	Grade 2	Grade 3	Grade 4	Grade 5
General	Mild	Moderate	Severe	Life-threatening	–
Neutropenia	Lowest baseline: 1500/mm^3 (1.5 × 10^9/L)	< 1500–1000/mm^3 (1.5–1 × 10^9/L)	< 1000–500/mm^3 (1–0.5 × 10^9/L)	< 500/mm^3 (0.5 × 10^9/L)	
Thrombocytopenia	Lowest baseline: 75,000/mm^3 (75 × 10^9/L)	< 75,000–50,000/mm^3 (75–50 × 10^9/L)	< 50,000–25,000/mm^3 (50–25 × 10^9/L)	< 25,000 mm^3 (25 × 10^9/L)	–
Diarrhea	Increase of less than four stools per day over baseline or mild increase in ostomy output compared to baseline	Increase of four to six stools per day over baseline; moderate increase in ostomy output compared with baseline; limiting ADLs	Increase of greater than or equal to seven stools per day over baseline; hospitalization; severe increase in ostomy output compared with baseline; limiting self-care ADL	Life-threatening consequences (eg, hemodynamic collapse); urgent intervention indicated	Death
Esophagitis	Asymptomatic clinical or diagnostic only; intervention not indicated	Symptomatic altered eating or swallowing; oral supplements indicated	Severely altered eating or swallowing; tube feedings, or TPN or hospitalization indicated	Life-threatening consequences; urgent operative intervention indicated	Death
Nausea	Loss of appetite without alteration in eating habits	Oral intake decreased without significant weight loss, dehydration, or malnutrition	Inadequate oral caloric or fluid intake; tube feedings, TPN or hospitalization indicated > 24 hours	–	–
Vomiting	Intervention not indicated	Outpatient intravenous hydration; medical intervention indicated	Tube feeding, TPN, or hospitalization indicated	Life-threatening consequences	Death

ADL, activity of daily living; IV, intravenous; TPN, total parenteral nutrition.

National Cancer Institute, Division of Cancer Treatment and Diagnosis | CTEP. Common Terminology Criteria for Adverse Events (CTCAE). Available from: https://ctep.cancer.gov/protocolDevelopment/electronic_applications/docs/CTCAE_v5_Quick_Reference_5x7.pdf (accessed October 14, 2020).

Table 88–6 lists the currently FDA-approved anticancer drugs by drug class and name. The next section will describe the most commonly used anticancer agents or those with unique mechanisms of action.

Antimetabolites: Pyrimidine Analogues

▶ *5-Fluorouracil and Capecitabine*

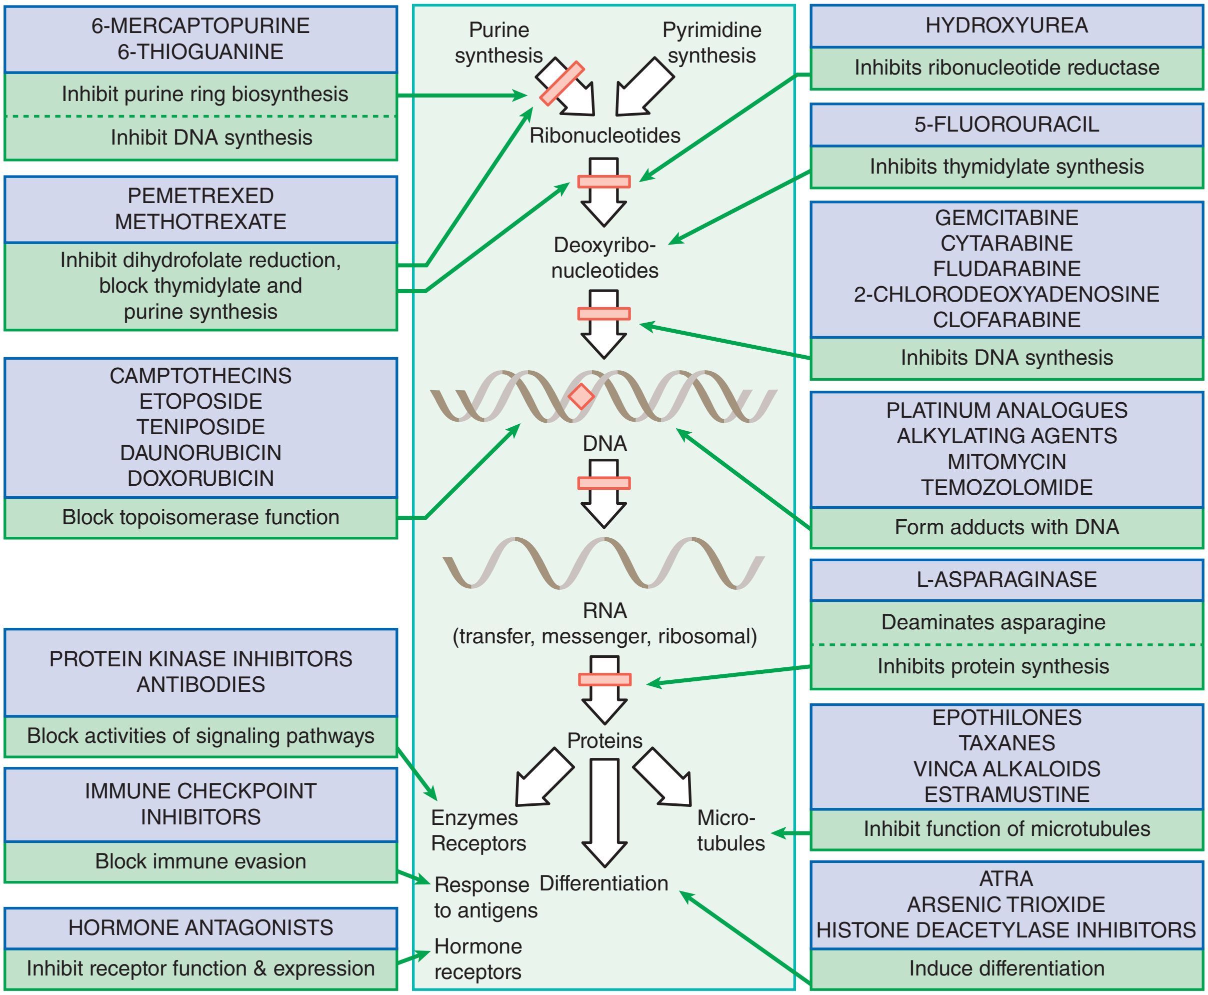
5-Fluorouracil (5-FU) is a fluorinated analogue of the pyrimidine uracil. Once administered, this prodrug is metabolized by dihydropyrimidine dehydrogenase (DPD). 5-Fluorouracil ultimately is metabolized to fluorodeoxyuridine monophosphate (FdUMP), which interferes with the function of thymidylate synthase (TS), a requirement of thymidine synthesis. The triphosphate metabolite of 5-fluorouracil is incorporated into ribonucleic acid (RNA) to produce the second cytotoxic effect. Inhibition of TS occurs with the continuous infusion regimens, whereas the triphosphate form is associated with bolus administration. Capecitabine is an orally active prodrug of 5-fluorouracil and is enzymatically converted to 5-fluorouracil, sharing the same mechanism of action. Patients with a low activity of DPD appear to be at risk for life-threatening toxicities. Folates, such as leucovorin, increase the stability of FdUMP–TS inhibition and enhance the drug activity in certain cancers. These agents have clinical activity in several solid tumors and are frequently used to treat both breast and colon cancer. The most common toxicities include myelosuppression when administered by intravenous (IV) bolus and palmar–plantar erythrodysesthesia, and diarrhea, when administered as continuous IV infusion or orally. Palmar–plantar erythrodysesthesia, also called hand–foot syndrome (HFS), refers to redness, itching, and blistering of the palms of the hands and soles of the feet. Patients should be counseled to notify the prescriber when this adverse effect occurs. Significant increases in international normalization ratio (INR) and prothrombin time may occur within several days when capecitabine is initiated in patients concomitantly receiving warfarin. The INR

Patient Encounter 1, Part 2

The decision to treat the patient with a systemic hormonal and chemotherapy regimen is made. He will be receiving the standard regimen of leuprolide 22.5 mg intramuscularly every 12 weeks indefinitely and docetaxel 75 mg/m^2/day (intravenous) IV infusion over 60 minutes on day 1 every 21 days × six cycles.

Before initiating this chemotherapy regimen in the patient, what patient-specific issues need to be addressed?

What adverse effects will the patient likely experience with these two drugs?



6-MERCAPTOPURINE
6-THIOGUANINE
Inhibit purine ring biosynthesis
Inhibit DNA synthesis
PEMETREXED
METHOTREXATE
Inhibit dihydrofolate reduction, block thymidylate and purine synthesis
CAMPTOTHECINS
ETOPOSIDE
TENIPOSIDE
DAUNORUBICIN
DOXORUBICIN
Block topoisomerase function
PROTEIN KINASE INHIBITORS
ANTIBODIES
Block activities of signaling pathways
IMMUNE CHECKPOINT INHIBITORS
Block immune evasion
HORMONE ANTAGONISTS
Inhibit receptor function & expression
Purine synthesis
Pyrimidine synthesis
Ribonucleotides
Deoxyribo-nucleotides
DNA
RNA
(transfer, messenger, ribosomal)
Proteins
Enzymes
Receptors
Micro-tubules
Response to antigens
Differentiation
Hormone receptors
HYDROXYUREA
Inhibits ribonucleotide reductase
5-FLUOROURACIL
Inhibits thymidylate synthesis
GEMCITABINE
CYTARABINE
FLUDARABINE
2-CHLORODEOXYADENOSINE
CLOFARABINE
Inhibits DNA synthesis
PLATINUM ANALOGUES
ALKYLATING AGENTS
MITOMYCIN
TEMOZOLOMIDE
Form adducts with DNA
L-ASPARAGINASE
Deaminates asparagine
Inhibits protein synthesis
EPOTHILONES
TAXANES
VINCA ALKALOIDS
ESTRAMUSTINE
Inhibit function of microtubules
ATRA
ARSENIC TRIOXIDE
HISTONE DEACETYLASE INHIBITORS
Induce differentiation

FIGURE 88–3. The mechanisms of action of commonly used antineoplastic agents. (Reproduced with permission from Wellstein A. General Principles of Chemotherapy. In: Brunton LL, Hilal-Dandan R, Knollman BC, eds. Goodman & Gilman's The Pharmacologic Basis of Therapeutics, 13th ed. New York, NY: McGraw-Hill; 2017.)

should be monitored closely or the patient may be switched to a low-molecular-weight heparin. Other drug interactions can also occur. Patients should be instructed to take capecitabine within 30 minutes after a meal to increase absorption of the drug.

▶ *Cytarabine*

Cytarabine is a structural analogue of cytosine and is phosphorylated intracellularly to the active triphosphate form, which inhibits DNA polymerase. The triphosphate form also may be incorporated into DNA to result in chain termination to prevent DNA elongation. The drug may be administered as a low-dose continuous infusion, high-dose intermittent infusion, and into the subdural space via intrathecal or intraventricular administration. A liposomal formulation is also available for less frequent administration into the central nervous system (CNS). Cytarabine is eliminated by the kidneys with a renal clearance of 90 mL/min (1.5 mL/s). Cytarabine has shown efficacy in the treatment of acute leukemias and some lymphomas. The toxicities of cytarabine in high doses include myelosuppression; cerebellar syndrome (ie, nystagmus, dysarthria, and ataxia); and chemical conjunctivitis, an eye irritation that requires prophylaxis with steroid eye drops. The risk of neurotoxicity is increased with high doses (more than 1 g/m^2), advanced age, and renal dysfunction. If cerebellar toxicity does occur, the drug needs to be discontinued immediately, and decisions regarding further therapy need to be carefully considered.[16]

▶ *Gemcitabine*

Gemcitabine is a deoxycytidine analogue that is structurally related to cytarabine. Gemcitabine inhibits DNA polymerase activity and ribonucleotide reductase to result in DNA chain elongation. Gemcitabine has activity in several solid tumors and some lymphomas. The toxicities include myelosuppression; flu-like syndrome with fevers during the first 24 hours after administration; rash that appears 48 to 72 hours after administration; and hemolytic uremic syndrome, a rare but life-threatening adverse effect. Patients should be counseled to use acetaminophen to treat the fevers during the first 24 hours; however, fevers occurring 7 to 10 days after gemcitabine are likely to be febrile neutropenia and need prompt treatment with broad-spectrum antibiotics.

▶ *Azacitidine and Decitabine*

Azacitidine and decitabine are nucleoside analogues approved for the treatment of patients with myelodysplastic syndrome (MDS), a hematopoietic disorder that can transform into acute myeloid leukemia (AML). Both of these agents cause cytotoxicity by directly incorporating in the DNA and inhibiting DNA methyltransferase, which causes hypomethylation of DNA.

Table 88–6

Anticancer Drugs

Drug Class	Drug Name
Alkylating agents	
Alkyl sulfonate	Busulfan
Nitrogen mustards	Bendamustine
	Chlorambucil
	Cyclophosphamide
	Ifosfamide
	Melphalan
	Mechlorethamine
Nitrosoureas	Carmustine
	Lomustine
Nonclassical	Lurbinectedin
	Mitomycin C
	Thiotepa
	Trabectedin
Platinum complexes	Carboplatin
	Cisplatin
	Oxaliplatin
Triazenes and hydrazine	Dacarbazine
	Procarbazine
	Temozolomide
Anthracene derivatives	Daunorubicin
	Doxorubicin
	Epirubicin
	Idarubicin
	Mitoxantrone
Antitumor antibiotics	Bleomycin
Antimetabolites	
Cytidine deaminase inhibitor	Cedazuridine
Folate Antagonists	Methotrexate
Purine analogs	Pemetrexed
	Pralatrexate
	Cladribine
	Clofarabine
	Fludarabine
	6-Mercaptopurine
	Pentostatin
	Thioguanine
Pyrimidine analogs	Azacitidine
	Capecitabine
	Cytarabine
	Decitabine
	5-Fluorouracil
	Gemcitabine
	Nelarabine
	Trifluridine/(tipiracil)[a]
Histone deacetylase (HDAC) inhibitors	Belinostat
	Panobinostat
	Romidepsin
	Tazemetostat
	Vorinostat
Hormonal therapies	
Antiandrogens	Bicalutamide
	Flutamide
	Nilutamide
Androgen receptor antagonist	Apalutamide
	Darolutamide
	Enzalutamide
Antiestrogens	Raloxifene
	Tamoxifen
Aromatase inhibitors	Anastrozole
	Exemestane
	Letrozole
CYP17 inhibitor	Abiraterone acetate
Luteinizing hormone–releasing hormone agonist	Goserelin
	Leuprolide
Luteinizing hormone–releasing hormone antagonist	Degarelix
Immunomodulatory agents	Lenalidomide
	Pomalidomide
	Thalidomide
Immunotherapy	
Cell-based immunotherapy	Sipuleucel-T
CAR T cell	Tisagenlecleucel
	Axicabtagene ciloleucel
	Brexucabtagene autoleucel
Checkpoint inhibitors	Atezolizumab
	Avelumab
	Cemiplimab
	Durvalumab
	Ipilimumab
	Nivolumab
	Pembrolizumab
Miscellaneous immune therapies	Interferons
	Aldesleukin
Microtubule-targeting agents	
Taxanes	Cabazitaxel
	Docetaxel
	Paclitaxel
Vinca alkaloids	Vinblastine
	Vincristine
	Vinorelbine
Other	Eribulin
	Estramustine
	Ixabepilone
Miscellaneous agents	Asparaginase
	Arsenic trioxide
	Bexarotene
	Calaspargase pegol
	Hydroxyurea
	Liposome encapsulated doxorubicin-cytarabine
	Omacetaxine mepesuccinate
	Pegaspargase
	Tagraxofusp
	Tretinoin
	Ziv-aflibercept
Monoclonal antibodies	Alemtuzumab
	Bevacizumab
	Blinatumomab
	Cetuximab
	Daratumumab
	Dinutuximab
	Elotuzumab
	Emapalumab
	Isatuximab
	Mogamulizumab
	Obinutuzumab
	Ofatumumab
	Olaratumab
	Necitumumab
	Panitumumab
	Pertuzumab
	Ramucirumab
	Rituximab
	Tafasitamab
	Trastuzumab

(Continued)

Table 88–6

Anticancer Drugs (*Continued*)

Drug Class	Drug Name
	Trastuzumab and hyaluronidase
Antibody–drug conjugate	Ado-trastuzumab emtansine
	Brentuximab vedotin
	Belantamab mafodotin
	Fam-trastuzumab deruxtecan
	Inotuzumab ozogamicin
	Gemtuzumab ozogamicin
	Moxetumomab pasudotox
	Polatuzumab vedotin
	Sacituzumab govitecan
Antibody–radioimmunotherapy conjugate	Ibritumomab tiuxetan
Topoisomerase inhibitors	
Camptothecin derivatives	Irinotecan
	Topotecan
Epipodophyllotoxins	Etoposide
Tyrosine kinase inhibitors	
Anaplastic lymphoma kinase (ALK)	Alectinib
	Brigatinib
	Ceritinib
	Crizotinib
	Lorlatinib
B-cell lymphoma 2 (Bcl-2)	Venetoclax
BCR-ABL	Bosutinib
	Dasatinib
	Imatinib
	Nilotinib
	Ponatinib
BRAF	Cobimetinib
	Dabrafenib
	Encorafenib
	Vemurafenib
Bruton's tyrosine kinase (BTK)	Acalabrutinib
	Ibrutinib
	Zanubrutinib
Cyclin-dependent kinase (CDK)	Abemaciclib
	Palbociclib
	Ribociclib
Epidermal growth factor receptor (EGFR)	Afatinib
	Dacomitinib
	Erlotinib
	Gefitinib
	Osimertinib
EGFR/HER2	Vandetanib
	Lapatinib
	Neratinib
	Tucatinib
Hedgehog pathway inhibitors	Glasdegib
	Sonidegib
	Vismodegib
Fibroblast growth factor receptor (FGFR)	Erdafitinib
	Pemigatinib
Isocitrate dehydrogenase 2 (IDH2)	Enasidenib
	Ivosidenib
Janus-associated kinase (JAK)	Fedratinib
	Ruxolitinib
	Binimetinib
	Capmatinib
Mitogen-activated extracellular kinase (MEK)	Cobimetinib
	Selumetinib
	Trametinib
Multikinase	Axitinib
	Brigatinib
	Cabozantinib
	Gilteritinib
	Lenvatinib
	Midostaurin
	Pazopanib
	Pexidartinib
	Regorafenib
	Ripretinib
	Sorafenib
	Sunitinib
	Vandetanib
Mammalian target of rapamycin (mTOR)	Everolimus
	Temsirolimus
Neurotrophic tyrosine receptor kinase (NTRK)	Entrectinib
	Larotrectinib
Phosphoinositide 3-kinase (PI3K)	Alpelisib
	Copanlisib
	Duvelisib
	Idelalisib
Platelet-derived growth factor receptor (PDGFR)	Avapritinib
	Pralsetinib
Poly ADP ribose polymerase (PARP)	Niraparib
	Olaparib
	Rucaparib
Proteasome inhibitors	Bortezomib
	Carfilzomib
	Ixazomib
RET tyrosine kinase (RET)	Selpercatinib
Selective inhibitor of nuclear export antagonist	Selinexor

[a] Tipiracil is a thymidine phosphorylase inhibitor used to increase bioavailability of trifluridine.

Hypomethylation of DNA appears to normalize the function of the genes that control cell differentiation and proliferation to promote normal cell maturation. Major side effects reported are myelosuppression and infections. Most recently an oral formulation of azacitidine was approved by the FDA.[17,18] Additionally, a combination product of an oral formulation of decitabine, along with the cytidine deaminase inhibitor cedazuridine, was approved for use in MDS. Cedazuridine prevents the breakdown of decitabine, thereby increasing its bioavailability and efficacy. Adverse events of these oral hypomethylating agents are similar to their IV counterparts.

Antimetabolites: Purine Analogues

▶ *Mercaptopurine*

6-Mercaptopurine (6-MP) is an oral purine analogue that is converted to ribonucleotides that inhibit purine synthesis. Mercaptopurine is converted into thiopurine nucleotides, which are catabolized by thiopurine *S*-methyltransferase (TPMT). TPMT is subject to genetic polymorphisms and may cause severe myelosuppression; therefore, TPMT status may be assessed before therapy to reduce drug-induced morbidity and the costs of hospitalizations for neutropenic events. 6-MP is used in the treatment of acute lymphocytic leukemia (ALL) and chronic myeloid leukemia (CML). Significant side effects include myelosuppression, mild nausea, skin rash, cholestasis, and rarely, veno-occlusive disease. Mercaptopurine is metabolized by xanthine oxidase, an enzyme that is inhibited by allopurinol. This represents a major drug–drug interaction. To avoid toxicities of mercaptopurine when these drugs are used concomitantly, the dose of mercaptopurine must be reduced by 66% to 75%.

▶ *Fludarabine*

Fludarabine is an analogue of the purine adenine. It interferes with DNA polymerase to cause chain termination and inhibits transcription by its incorporation into RNA. Fludarabine is dephosphorylated rapidly and converted to 2-fluoro-Ara-AMP (2-FLAA), which enters the cells and is phosphorylated to 2-fluoro-Ara-ATP, which is cytotoxic. Fludarabine is used in the treatment of chronic lymphocytic leukemia (CLL), some lymphomas, and refractory AML. Significant and prolonged myelosuppression may occur, along with immunosuppression, so patients are susceptible to opportunistic infections. Prophylactic antibiotics and antivirals are recommended until cluster of differentiation (CD) 4 counts return to normal. Mild nausea and vomiting and diarrhea have been observed. Rarely, interstitial pneumonitis has occurred.

Antimetabolites: Folate Antagonists

Folates carry one-carbon groups in transfer reactions required for purine and thymidylic acid synthesis. Dihydrofolate reductase is the enzyme responsible for supplying reduced folates intracellularly for thymidylate and purine synthesis.

▶ *Methotrexate*

Methotrexate inhibits dihydrofolate reductase of both malignant and nonmalignant cells. When high doses of methotrexate are given, the "rescue drug" leucovorin, a reduced folate, is administered to bypass the methotrexate inhibition of dihydrofolate reductase of normal cells and is usually initiated 24 hours after methotrexate administration. This is done to prevent potentially fatal myelosuppression and mucositis. For safety purposes, the term folinic acid, another term used for leucovorin, should not be used because of the potential for a medication error in which folic acid might be given instead. Methotrexate concentrations should be monitored to determine when to stop leucovorin administration. Generally, leucovorin administration may be stopped when methotrexate concentrations decrease to 5×10^{-8} M, although this may vary by the chemotherapy regimen. Higher doses of methotrexate may place an individual at risk for methotrexate to crystallize in the acidic environment of the urine, often resulting in acute renal failure and decreased methotrexate clearance. Administration of IV hydration with sodium bicarbonate to maintain urinary pH greater than or equal to 7 is necessary to prevent methotrexate-induced renal dysfunction. Methotrexate is eliminated by tubular secretion; therefore, concomitant drugs (eg, probenecid, salicylates, penicillin G, and ketoprofen) that may inhibit or compete for tubular secretion should be avoided. Methotrexate doses must be adjusted for renal dysfunction and close monitoring of methotrexate concentrations is advised. In patients with toxic levels of methotrexate (> 1 μmol/L) because of impaired renal function, the antidote glucarpidase can be administered. However, efficacy can be compromised so it is not used in patients with normal or slightly elevated levels. Side effects of methotrexate include myelosuppression, nausea and vomiting, and mucositis. Methotrexate may also be administered via the intrathecal route or via an Ommaya reservoir in very low doses as small as 12 mg, so it is crucial for the clinician to know the correct dose by the correct route in order to avoid substantial toxicity. The methotrexate used for intrathecal and intraventricular injection must be preservative-free to prevent CNS toxicity.

▶ *Pemetrexed*

Pemetrexed inhibits four pathways in thymidine and purine synthesis. Pemetrexed has shown activity in the treatment of mesothelioma and non–small cell lung cancer (NSCLC). Side effects include myelosuppression, rash, diarrhea, and nausea and vomiting. Patients should receive folic acid and cyanocobalamin to reduce bone marrow toxicity and diarrhea. Doses of folic acid of at least 400 mcg/day starting 7 days before treatment and continuing throughout therapy, as well as for 21 days after the last pemetrexed dose, have been used.[18] Cyanocobalamin 1000 mcg is given intramuscularly the week before pemetrexed and then every three cycles thereafter. Dexamethasone 4 mg twice daily the day before, the day of, and the day after pemetrexed administration helps to decrease the incidence and severity of rash.

Microtubule-Targeting Agents

▶ *Vinca Alkaloids (Vincristine, Vinblastine, and Vinorelbine)*

The vinca alkaloids (vincristine, vinblastine, and vinorelbine) are derived from the periwinkle (vinca) plant and cause cytotoxicity by binding to tubulin, disrupting the normal balance between polymerization and depolymerization of microtubules, and inhibiting the assembly of microtubules, which interferes with the formation of the mitotic spindle. As a result, cells are arrested during the metaphase of mitosis. The vinca alkaloids are used in several malignancies, primarily hematologic. Even though these agents have similar structures, the incidence and severity of toxicities vary. The dose-limiting toxicity of vincristine is neurotoxicity, which can consist of depressed tendon reflexes, paresthesias of the fingers and toes, toxicity to the cranial nerves, or autonomic neuropathy (constipation or ileus, abdominal pain, and/or orthostatic hypotension). In contrast, the dose-limiting toxicity associated with vinorelbine and vinblastine is myelosuppression. All of the vinca alkaloids are vesicants and can cause tissue damage; therefore, extravasation needs to be prevented. Biliary excretion accounts for a significant portion of elimination of vincristine and its metabolites, so doses need to be adjusted for obstructive liver disease.

Vincristine, vinblastine, and vinorelbine have similar sounding names, which is a potential cause of medication errors. As with all chemotherapy prescribing, dispensing, and administration, the clinician must be very careful with sound-alike, look-alike medications. Unfortunately, vincristine has been involved in numerous cases of fatal chemotherapy errors, including inadvertent intrathecal administration. When administered intrathecally, widespread tissue damage and potentially deaths can occur. An example of a strategy that health systems can use to decrease the likelihood of an error such as this is for the pharmacy to only dispense vincristine in a mini-bag for IV administration. Many clinicians cap IV vincristine doses at 2 mg to prevent severe neuropathic side effects; however, if the intent of chemotherapy is curative, the vincristine dose may be dosed above the 2-mg cap.[19]

▶ Taxanes (Cabazitaxel, Docetaxel, Nanoparticle Albumin-Bound Paclitaxel, and Paclitaxel)

Taxane plant alkaloids are similar to the vinca alkaloids, exhibiting cytotoxicity during the M phase of the cell cycle by binding to tubulin. Unlike the vinca alkaloids, however, the taxanes do not interfere with tubulin assembly. Rather, the taxanes promote microtubule assembly and inhibit microtubule disassembly. Once the microtubules are polymerized, the taxanes stabilize against depolymerization.

Hepatic metabolism and biliary excretion account for the majority of paclitaxel's elimination. Paclitaxel has demonstrated activity in several solid tumors. The diluent for paclitaxel, Cremophor EL, is composed of ethanol and castor oil. Infusions must be prepared and administered in non–polyvinyl chloride–containing bags and tubing, and solutions must be filtered. Patients receive dexamethasone, diphenhydramine, and an histamine $(H)_2$ blocker to prevent hypersensitivity reactions caused by Cremophor EL. Patients also may have asymptomatic bradycardia during the infusion. Approximately 3 to 5 days after administration, patients may complain of myalgias and arthralgias that may last several days. Myelosuppression, flushing, neuropathy, ileus, and total-body alopecia are other common side effects. Because paclitaxel is a substrate for cytochrome P450 (CYP)-3A4, patients receiving phenytoin (a strong CYP3A4 inducer) had lower steady-state concentration of paclitaxel than patients not receiving phenytoin and this combination should be avoided. In addition, paclitaxel clearance is decreased by 33% when it was administered after cisplatin, so for regimens containing both agents, paclitaxel is administered before cisplatin.

A nanoparticle albumin-bound nab-paclitaxel product is also available for the treatment of metastatic breast cancer resistant to conventional chemotherapy. The nab-paclitaxel formulation uses nanotechnology to combine human albumin with paclitaxel allowing for the delivery of an insoluble drug in the form of nanoparticles. This unique formulation allows for an increased bioavailability and higher intracellular concentrations of the drug. It does not have the serious hypersensitivity reactions encountered with paclitaxel solubilized in Cremophor EL, so premedication with H_1 and H_2 blockers and steroids is not necessary. Also, a significantly lower incidence of severe neutropenia occurs with nab-paclitaxel. The dose is infused over 30 minutes and does not require a special IV bag, tubing, or filter. The dosing of this product is also different from that of the original paclitaxel and the formulation needs to be clearly indicated when prescribed. The pharmacokinetics of the albumin-bound paclitaxel displays a higher clearance and larger volume of distribution than paclitaxel. The drug is eliminated primarily via fecal excretion. Bone marrow suppression, neuropathy, ileus, arthralgias, and myalgias still occur.

Docetaxel has activity in the treatment of several solid tumors. Dexamethasone, 8 mg twice daily for 3 days starting the day before treatment, is used to prevent the fluid-retention syndrome associated with docetaxel and possible hypersensitivity reactions. The fluid-retention syndrome is characterized by edema and weight gain that is unresponsive to diuretic therapy and is associated with cumulative doses greater than 800 mg/m². Myelosuppression, alopecia, and neuropathy are other side effects associated with docetaxel treatment.

Cabazitaxel is a newer taxane used in combination with prednisone for the treatment of metastatic hormone-refractory prostate cancer. Cabazitaxel has shown to have similar adverse effects as paclitaxel and docetaxel. Premedication with an antihistamine, corticosteroid, and H_2 antagonist to prevent hypersensitivity reactions is required.

▶ Eribulin

Eribulin mesylate is a nontaxane microtubule dynamics inhibitor. It is a synthetic analogue of halichondrin B, which is a product isolated from the sea sponge *Halichondria okadai*. While taxanes inhibit cell division by stabilizing microtubules, eribulin arrests the cell cycle through inhibition of the growth phase of microtubules without interfering with microtubule shortening. The cytotoxicity results from its effects via a tubulin-based antimitotic mechanism, resulting in G_2/M cell cycle arrest and mitotic blockage. Apoptotic cell death results from prolonged mitotic blockage. Eribulin mesylate is an IV medication that is specifically indicated for the treatment of patients with metastatic breast cancer and liposarcoma. The most common adverse effects reported are neutropenic fever, anemia, asthenia or fatigue, alopecia, peripheral neuropathy, nausea, and constipation. Eribulin has been reported to cause significant neutropenia and QTc interval prolongation. It has vesicant properties. Dosages should be adjusted in renal and hepatic impairment.

▶ Ixabepilone

Ixabepilone, an epothilone analogue, binds to β-tubulin subunits on microtubules, which results in suppression of microtubule dynamics. Ixabepilone is primarily eliminated by the liver by oxidation through the CYP3A4 system. Ixabepilone, in combination with capecitabine or alone if resistant to capecitabine, is indicated for the treatment of metastatic or locally advanced breast cancer. Studies have shown a possible synergy when used in combination with capecitabine. Side effects include hypersensitivity reactions, myelosuppression, and peripheral neuropathy. To minimize the occurrence of hypersensitivity reactions, patients must receive both H_1 and H_2 antagonists before therapy. If a reaction still occurs, corticosteroids should be added to the premedications.

Topoisomerase Inhibitors

Topoisomerase is responsible for relieving the pressure on the DNA structure during unwinding by producing strand breaks. Topoisomerase I produces single-strand breaks, whereas topoisomerase II produces double-strand breaks.

▶ Epipodophyllotoxins (Etoposide)

Etoposide is a semisynthetic podophyllotoxin derivative that inhibits topoisomerase II, causing multiple DNA double-strand breaks. Etoposide has shown activity in the treatment of several types of lymphoma, testicular and lung cancer, retinoblastoma, and carcinoma of unknown primary. Oral bioavailability is approximately 50%, so oral dosages are approximately two times those of IV doses. It should be slowly administered to prevent hypotension. Side effects include mucositis, myelosuppression, alopecia, phlebitis, hypersensitivity reactions, and secondary leukemias. Hypersensitivity reactions are caused by the solubilizing agents, polysorbate 80 and may be life-threatening.

▶ Camptothecin Derivatives (Irinotecan and Topotecan)

Irinotecan and topotecan, both camptothecins, inhibit the topoisomerase I enzyme to interfere with DNA synthesis through the active metabolite SN-38. Topoisomerase I enzymes stabilize DNA single-strand breaks and inhibit strand resealing. Irinotecan has shown activity in the treatment of cancers of the colon, rectum, cervix, and lung. Irinotecan-induced diarrhea is a serious complication and may be life-threatening. One form of diarrhea (early) can occur during or immediately after the infusion. This is a result of a cholinergic process in which the patient may experience facial flushing, diaphoresis, and abdominal cramping. IV atropine should be administered to treat diarrhea that occurs any time during the first 24 hours of administration. Another form of diarrhea (late) can occur several days after administration and can result in severe dehydration. This adverse effect should be treated immediately with loperamide at a dosage of 2 mg every 2 hours or 4 mg every 4 hours until diarrhea has stopped for 12 hours. Other side effects include myelosuppression, fatigue, and alopecia. Individuals homozygous for *UGT1A1*28* have an increased risk of febrile neutropenia and diarrhea and should be considered for an empiric dose reduction of one level; heterozygotes should receive closer monitoring, including more frequent CBCs to detect myelosuppression.

Topotecan has shown clinical activity in the treatment of ovarian and lung cancer, MDS, and AML. The IV infusion may be scheduled daily for 5 days or once weekly. Side effects include myelosuppression, mucositis, and diarrhea. Diarrhea is less common than with irinotecan.

Anthracene Derivatives

▶ *Daunorubicin, Doxorubicin, Idarubicin, and Epirubicin*

Anthracyclines (daunorubicin, doxorubicin, idarubicin, and epirubicin) are also referred to as antitumor antibiotics or topoisomerase inhibitors when considering their mechanism of action. All of the anthracyclines contain a four-membered anthracene ring, a chromophore, with an attached sugar portion. This chromophore results in red-orange urine after administration, which is an important counseling point for patients. Free radicals formed from the anthracyclines combine with oxygen to form superoxide, which can make hydrogen peroxide. These agents are able to insert between base pairs of DNA to cause structural changes in DNA. However, the primary mechanism of cytotoxicity appears to be the inhibition of topoisomerase II. These drugs are widely used in a variety of cancers.

Oxygen-free-radical formation is a cause of cardiac damage and extravasation injury, which is common with these drugs. The anthracyclines can cause cardiac toxicity as manifested by a congestive heart failure or cardiomyopathy symptomatology, alopecia, nausea or vomiting, mucositis, myelosuppression, and urinary discoloration. These drugs are vesicants.

To reduce the risk of cardiotoxicity associated with doxorubicin, the maximum lifetime cumulative dose is 550 mg/m^2; similarly, the other anthracyclines have maximum lifetime cumulative doses. Ventricular ejection fractions should be measured before therapy and periodically if therapy is continued. Therapy should be halted if there is a 10% to 20% decrease from baseline in ejection fraction. Patients at increased risk of cardiotoxicity include patients reaching the upper limit of cumulative lifetime dose; those taking concomitant or previous cardiotoxic drugs, concurrent paclitaxel, or bolus administration; patients with preexisting cardiac disease or mediastinal radiation; and the very young and elderly. Cardioprotectants (eg, dexrazoxane) have been used to decrease risk in some cases. Clinical guidelines for cardioprotective agents' use are available.[20]

Liposomal doxorubicin is an **irritant**, not a vesicant, and is dosed differently from doxorubicin and formulation must be clearly specified when prescribing. Liposomal doxorubicin may also be less cardiotoxic than doxorubicin. Liposomal doxorubicin has significant activity in the treatment of breast and ovarian cancer along with multiple myeloma (MM) and Kaposi sarcoma. Side effects include mucositis, myelosuppression, alopecia, and palmar–plantar erythrodysesthesia.

Liposomal daunorubicin is also available but only in a combination product with liposomal cytarabine used in the treatment of AML. This product uses a synergistic ratio of daunorubicin to cytarabine (1:5) in a liposomal formulation to enhance exposure within the bone marrow. The dosing of this drug is different than traditional daunorubicin and cytarabine.

▶ *Mitoxantrone*

Mitoxantrone is a royal blue–colored anthracenedione that inhibits DNA topoisomerase II. Mitoxantrone has clinical activity in the treatment of acute leukemias, breast and prostate cancer, and non-Hodgkin lymphomas with myelosuppression, mucositis, nausea and vomiting, and cardiac toxicity its major adverse effect. The total cumulative dose limit is 160 mg/m^2 for patients who have not received prior anthracycline or mediastinal radiation. Patients with prior doxorubicin or daunorubicin therapy should not receive a cumulative dose greater than 120 mg/m^2 of mitoxantrone. Patients should be counseled that their urine will turn a blue-green color.

Alkylating Agents

Although still widely used for many malignancies, the alkylating agents are the oldest class of anticancer drugs. The agents cause cytotoxicity via transfer of their alkyl groups to nucleophilic groups of proteins and nucleic acids. The major site of alkylation within DNA is the N7 position of guanine, although alkylation does occur to a lesser degree at other bases. These interactions can either occur on a single strand of DNA (monofunctional agents) or on both strands of DNA through a cross-link (bifunctional agents), which leads to strand breaks. The major toxicities of the alkylating agents are myelosuppression, alopecia, nausea or vomiting, sterility or infertility, and secondary malignancies.

▶ *Nitrogen Mustards (Cyclophosphamide and Ifosfamide)*

Cyclophosphamide and ifosfamide are bifunctional alkylating agents with similar adverse effects and activity and are used in a variety of solid and hematologic cancers. Both are prodrugs, requiring activation by mixed hepatic oxidase enzymes to phosphoramide and ifosfamide mustard. During the activation process, additional byproducts (acrolein and chloroacetaldehyde) are formed. Acrolein has no cytotoxic activity but is responsible for the hemorrhagic cystitis associated with ifosfamide and high-dose cyclophosphamide. Acrolein produces cystitis by directly binding to the bladder wall. Prophylaxis is necessary with aggressive hydration, administration of 2-mercaptoethane sulfonate sodium (mesna, which binds to and inactivates acrolein in the bladder), frequent voiding, and monitoring in patients receiving ifosfamide and high-dose cyclophosphamide. Patients should be counseled to drink plenty of fluids; void frequently; and report any hematuria, irritation, or flank pain. Dosing regimens of mesna range from an equal milligram dose to the ifosfamide mixed in the same IV bag to 20% of the dose administered before ifosfamide and 20% of the dose repeated at 4 and 8 hours after the ifosfamide dose.

Chloroacetaldehyde, a metabolite of ifosfamide, can result in encephalopathy, especially in patients with renal dysfunction or advanced age. This adverse effect can occur within 48 to 72 hours of administration and is usually reversible.

▶ Busulfan

Busulfan is an alkylating agent that forms DNA–DNA and DNA–protein cross-links to inhibit DNA replication. Oral busulfan is well absorbed, has a terminal half-life of 2 to 2.5 hours, and is eliminated primarily by hepatic metabolism. It is also available in an IV formulation, which is commonly used for high doses, to reduce pill burden. Busulfan has significant clinical activity in the treatment of AML and CML and has been used as a conditioning regimen before hematopoietic stem cell transplantation (HSCT). Side effects include bone marrow suppression; hyperpigmentation of skin creases; and rarely, pulmonary fibrosis. High doses used for HSCT preparatory regimens can cause severe nausea and vomiting, tonic–clonic seizures, and sinusoidal obstruction syndrome and require anticonvulsant prophylaxis. A discussion of busulfan adaptive dosing can be found in Chapter 98.

▶ Nitrosoureas (Carmustine and Lomustine)

Carmustine (BCNU) and lomustine (CCNU) are lipophilic nitrosureas that can cross the blood–brain barrier. Carmustine may be administered IV or as a biodegradable wafer formulation that is implanted during surgical resection of brain tumors. Lomustine is available in an oral formulation. Carmustine has shown clinical activity in the treatment of lymphoma, MM, and brain tumors. Lomustine has shown clinical activity in the treatment of non-Hodgkin lymphoma and brain tumors. Side effects include myelosuppression, severe nausea and vomiting, and pulmonary fibrosis with long-term therapy.

▶ Nonclassic Alkylating Agents (Dacarbazine and Temozolomide)

Although the exact mechanism of action remains unclear, dacarbazine and temozolomide appear to inhibit DNA, RNA, and protein synthesis. Dacarbazine is used to treat melanoma, Hodgkin lymphoma, and soft tissue sarcomas. Side effects include myelosuppression, severe nausea and vomiting, and a flu-like syndrome that starts about 7 days after treatment and lasts 1 to 3 weeks.

Temozolomide is a well-absorbed orally active agent that also crosses the blood–brain barrier. Temozolomide is converted via pH-dependent hydrolysis to the active metabolite 5-(3-methyltriazeno)-imidazole-4-carboxamide. Temozolomide may be used in the treatment of melanoma, refractory anaplastic astrocytoma, and glioblastoma multiforme. Nausea may be minimized by administering the drug at bedtime. Because patients receiving temozolomide may have confusion secondary to their brain tumors and dosing can consist of multiple capsule sizes, care must be taken by all providers to simplify regimens to prevent chemotherapy overdose.[21]

▶ Procarbazine

Although the exact mechanism of action of procarbazine is unknown, it does inhibit DNA, RNA, and protein synthesis. Procarbazine is used most often in the treatment of lymphoma. Myelosuppression is the major side effect. Nausea, vomiting, and a flu-like syndrome occur initially with therapy. Patients must be counseled to avoid tyramine-rich foods because procarbazine is a monoamine oxidase inhibitor. Patients should be provided a list of foods and beverages to avoid a hypertensive crisis. A disulfiram-like reaction can occur with the ingestion of alcohol.

Heavy Metal Compounds

Platinum drugs form reactive platinum complexes that bind to cells, so the pharmacokinetics of the individual drug may be of the platinum, both free and bound, rather than of the parent drug.

▶ Cisplatin

Cisplatin forms inter- and intrastrand DNA cross-links to inhibit DNA synthesis. Cisplatin has clinical activity in the treatment of numerous tumor types and remains front-line therapy for lung and ovarian cancers. Cisplatin is highly emetogenic, even when low doses are given daily for 5 days, and causes delayed nausea and vomiting as well; patients require aggressive antiemetic regimens for both delayed and acute emesis. Significant nephrotoxicity and electrolyte abnormalities can occur if inadequate hydration occurs. Ototoxicity, which manifests as a high-frequency hearing loss, and a glove-and-stocking neuropathy may limit therapy.

▶ Carboplatin

Carboplatin has the same mechanism of action as cisplatin; however, its side effects are similar but less intense than those of cisplatin. Many chemotherapy regimens dose carboplatin based on an area under the curve (AUC), also called the Calvert equation. According to the Calvert equation for adults, the dose in milligrams of carboplatin = (creatinine clearance [CrCl] + 25) × AUC desired, where CrCl is expressed in mL/min.[22] Carboplatin has shown clinical activity in the treatment of several solid tumors and lymphoma. Thrombocytopenia, nausea and vomiting, and hypersensitivity reactions are common adverse effects.

▶ Oxaliplatin

Oxaliplatin is commonly used to treat colorectal cancer. Its adverse effect profile is similar to cisplatin with hypersensitivity reactions and moderate nausea and vomiting commonly observed.[23] In addition, oxaliplatin can cause cold-induced neuropathy. Patients should be counseled to avoid cold beverages, to use gloves to remove items from the freezer, and to wear protective clothing in cold climates for the first week after treatment. A glove-and-stocking neuropathy also occurs with long-term administration.

Miscellaneous Agents

▶ Bleomycin

Bleomycin is a mixture of peptides with drug activity expressed in units, where 1 U equals to 1 mg. Bleomycin causes DNA strand breakage. Bleomycin has activity in testicular cancer and malignant effusions, squamous cell carcinomas of the skin, and Kaposi sarcoma. Hypersensitivity reactions and fever may occur, so premedication with acetaminophen may be required. The most serious side effect of bleomycin is pulmonary toxicity that presents as a pneumonitis with a dry cough, dyspnea, rales, and infiltrates. Pulmonary function studies show decreased carbon monoxide diffusing capacity and restrictive ventilatory changes. “Bleomycin lung” is associated with cumulative dosing greater than 400 U and occurs rarely with a total dose of 150 U and is potentiated by thoracic radiation and by hyperoxia. Additional side effects include fever with or without chills, mild-to-moderate alopecia, and nausea and vomiting.

Bleomycin is also used to manage malignant plural effusions at doses of 15 to 60 U through installation into the affected area. The drainage tube of the effusion is clamped off for some period of time after administration of bleomycin and then the amount of drainage is monitored to determine efficacy of the treatment.[23]

▶ Hydroxyurea

Hydroxyurea is an oral drug that inhibits ribonucleotide reductase, which converts ribonucleotides into the deoxyribonucleotides used in DNA synthesis and repair. Hydroxyurea has activity in CML, polycythemia vera, sickle cell disease, and thrombocytosis. The major side effects are myelosuppression, nausea and vomiting, diarrhea, and constipation. Rash, mucositis, and renal tubular dysfunction occur rarely.

▶ L-Asparaginase

L-Asparaginase is an enzyme that may be produced by *Escherichia coli*. Asparaginase hydrolyzes the reaction of asparagine to aspartic acid and ammonia to deplete lymphoid cells of asparagine, which inhibits protein synthesis. L-Asparaginase has activity in ALL and childhood AML. Severe allergic reactions may occur when the interval between doses is 7 days or greater, so while a skin test result may be negative, patients should be observed closely after asparaginase administration. If the patient suffers an allergic reaction to L-asparaginase, alternatively formulated agents, such as pegaspargase or calaspargase pegol, may be given. These drugs include L-asparaginase modified through a linkage with polyethylene glycol or monomethoxypolyethylene glycol, respectively, which extends the half-life and allows for lower doses and less-frequent administration. Cost and limited availability limit their use in the front line setting.

▶ Tretinoin

Tretinoin, also referred to as all-*trans*-retinoic acid (ATRA), is used to treat acute promyelocytic leukemia (APL). ATRA is a retinoic acid that is not cytotoxic but promotes the maturation of early promyelocytic cells that have the charatersitic t(15;17) translocation. A severe side effect of ATRA is retinoic acid syndrome, which may occur anytime during treatment and consists of fever, respiratory distress, and hypotension. Chest radiographs are consistent with a pneumonia-like process and it is important to differentiate pneumonia from APL syndrome, as the treatment for retinoic acid syndrome is dexamethasone 10 mg IV every 12 hours, which may be detrimental to administer to a neutropenic patient with pneumonia.

▶ Immunomodulatory Agents (Thalidomide, Lenalidomide, and Pomalidomide)

Thalidomide was initially approved in Europe on October 1, 1957, as a sedative–hypnotic. Some children born to women who had taken thalidomide were born with severe limb deformities (phocomelia) which led to its removal from the market. Thalidomide was subsequently identified an angiogenesis inhibitor, with clinical activity in the treatment of MM. Patients receiving thalidomide are enrolled in the Risk Evaluation and Mitigation Strategies (REMS) program and counseled on the risks of phocomelia should they become pregnant. Common adverse effects include somnolence, constipation, peripheral neuropathy, and deep vein thrombosis (DVT). Recommendations for DVT prophylaxis for all thalidomides is based upon a risk-assessment model whereby prophylaxis with low-molecular-weight heparin or dose-adjusted warfarin is recommended for high-risk patients and aspirin for low-risk patients.[24]

Lenalidomide is approved for the treatment of MDS when the 5q deletion is present and MM. Because lenalidomide is an analogue of thalidomide, all of the same precautions must be taken to prevent phocomelia. However, lenalidomide has fewer adverse effects than thalidomide. Dosing adjustments are necessary for renal dysfunction. Other side effects are neutropenia, thrombocytopenia, DVT, and pulmonary embolus.

Pomalidomide is also used in treatment of refractory or progressive MM and Kaposi's sarcoma. Similar precautions to prevent phocomelia are also required. Adverse effects include myelosuppression and infections. The use of the immunomodulatory agents in the treatment of MM is discussed thoroughly in Chapter 96.

▶ Omacetaxine Mepesuccinate

Omacetaxine mepesuccinate is an alkaloid from *Cephalotaxus harringtonia*. The agent reversibly inhibits protein synthesis, causing cell death in both malignant and nonmalignant cells. It is a subcutaneous (SC) injection and is indicated for the treatment of CML patients (including those patients with the T315I mutation) showing resistance and/or intolerance to two or more tyrosine kinase inhibitors (TKIs). The most common nonhematological adverse effects are gastrointestinal (GI) disruption, fatigue, and hyperglycemia. Rare but serious adverse reactions include febrile neutropenia, infections, and cerebral hemorrhage.

▶ Histone Deacetylase (HDAC) Inhibitors (Belinostat, Panobinostat, Romidepsin, Tazemetostat, and Vorinostat)

Histone deacetylase (HDAC) inhibitors agents catalyze the removal of acetyl groups from acetylated lysine residues in histones, resulting in the modulation of gene expression. Belinostat, romidepsin, and vorinostat are used for the treatment of cutaneous T-cell lymphoma; panobinostat for MM; and tazemetostat for epithelioid sarcoma and follicular lymphoma. Panobinostat, tazemetostat, and vorinostat are orally available agents, and belinostat and romidepsin are only available in an IV formulation. These drugs are metabolized by CYP3A4 and have potential drug interactions strong CYP3A inducers and inhibitors. Side effects include fatigue, myelosuppression, and GI toxicities. Tazemetostat and vorinostat are associated with hypercholesterolemia, hypertriglyceridemia, and hyperglycemia. Despite anemia, thrombocytopenia, and neutropenia, patients receiving vorinostat have developed pulmonary embolism and DVT while on therapy. Panobinostat carries a boxed warning for severe diarrhea (occurring in 25% of patients) and cardiac events, severe arrhythmia and electrocardiogram changes that can be exacerbated by electrolyte abnormalities. Tazemetostat has a risk of a developing a second primary hematologic malignancy.

Immunotherapy

▶ Chimeric Antigen Receptor (CAR) T-Cell Therapies (Axicabtagene ciloleucel, Brexucabtagene autoleucel, Tisagenlecleucel)

One of the newer immunotherapy classes is the chimeric antigen receptor (CAR) T-cell therapies that are autologous T-cell immunotherapies comprising T cells that are genetically modified using a vector to encode an anti-CD19 CAR. Axicabtagene ciloleucel, brexucabtagene autoleucel and tisagenlecleucel are prepared from the patient's own peripheral mononuclear cells, which are obtained through a leukapheresis procedure.[18] The cells are sent to a laboratory whereby they are enriched with the lentiviral vector containing anti-CD19 CAR transgene. The transduced T cells are then expanded and formulated into a suspension that is cryopreserved. Once passing a sterility test, it is shipped back in a patient-specific infusion bag to the institution for administration. Axicabtagene ciloleucel is approved for large B-cell lymphoma; brexucabtagene autoleucel is approved for mantle cell lymphoma; and tisagenlecleucel is approved for us in ALL and diffuse large B-cell lymphoma. The most common side effect is a cytokine-release syndrome (CRS), which can be fatal. CRS occurs when the cytokines are released by activated T cells, producing a systemic inflammatory response. Patients may initially present with a low-grade fever, fatigue, and anorexia which can quickly progress to high fever, hypoxia, and organ failure. Immediate identification and treatment is necessary to prevent death. Another potentially serious side effect is neurotoxicity which often manifests within 4 to 10 days and can be mild such as headache and dizziness but can progress to delirium, aphasia, seizures, and encephalopathy. NCCN has guidelines on monitoring and treating CRS, neurologic symptoms, and other CAR T-cell therapy toxicities.[25] Other side effects include decreased appetite, headache, nausea/vomiting, infections, and diarrhea.

Monoclonal Antibodies

The cell surface contains molecules, which are referred to as *CD*. The antibodies are produced against a specific antigen. When administered, usually by an IV injection, the antibody binds to the antigen, which may trigger the immune system to result in cell death through complement-mediated cellular toxicity, or the antigen–antibody cell complex may be internalized to the cancer cell, which results in cell death. Monoclonal antibodies may also carry radioactivity, sometimes referred to as *hot antibodies*, and are referred to as *radioimmunotherapy*, so the radioactivity is delivered to the cancer cell. Antibodies that contain no radioactivity are referred to as *cold antibodies*.

All monoclonal antibodies end in the suffix *-mab*. The syllable before *-mab* indicates the source of the monoclonal antibody (Table 88–7).[26] When administering an antibody for the first time, one should consider the source. The less humanized an antibody, the greater the chance for the patient to have an allergic-type reaction to the antibody. The more humanized the antibody, the lower the risk of a reaction. The severity of the reactions may range from fever and chills to life-threatening allergic reactions. Premedication with acetaminophen and diphenhydramine is common before the first dose of any antibody. If a severe reaction occurs, the infusion should be stopped and the patient treated with antihistamines, corticosteroids, or other supportive measures.

Table 88–7

Syllable Source Indicators for Monoclonal Antibodies[a]

U	Human
O	Mouse
Xi	Chimeric: A cross between humanized and animal source
Axo	Rat/mouse hybrid
Xizu	Combination of humanized and chimeric chains

[a]These letters appear before mab, which stands for monoclonal antibody.

Data from American Medical Association. Monoclonal Antibodies. Available from: https://www.antibodysociety.org/wordpress/wp-content/uploads/2017/07/INN-2017-Reference-20.pdf (accessed October 10, 2020).

Many monoclonal antibodies now have biosimilar products approved in the United States for cancer treatment. A biosimilar is a type of biological product that is highly similar to the originator product and is expected to have no meaningful clinical difference. They are thought to be interchangeable from the innovator product. New biologics approved by the FDA now have a four-letter suffix to differentiate innovator and biosimilar products.

▶ Alemtuzumab

Alemtuzumab is an antibody to the CD52 receptor present on B and T lymphocytes. Alemtuzumab has shown clinical activity in the treatment of CLL. Severe and prolonged (6 months) immunosuppression may result, which necessitates *Pneumocystis jiroveci* pneumonia (PJP) prophylaxis and antifungal and antiviral prophylaxis to prevent opportunistic infections. Infusion-related reactions typically occur with the first dose and can be severe. Premedication with antihistamines and acetaminophen is recommended. SC administration will also alleviate the severity of infusion reactions.

▶ Bevacizumab

Bevacizumab is a humanized monoclonal antibody that binds to vascular endothelial growth factor (VEGF), which prevents it from binding to its receptors, ultimately resulting in inhibition of angiogenesis. Bevacizumab has shown clinical activity in the treatment of breast, colorectal, glioblastoma, gynecologic, head and neck, kidney, and lung cancer. Patients treated with bevacizumab products may develop hypertension requiring chronic medication during therapy. Impaired wound healing, thromboembolic events, proteinuria, bleeding, and bowel perforation are serious side effects that occur with this drug.

▶ Blinatumomab

Blinatumomab is a bispecific CD19-directed CD3 T-cell therapy. It activates T cells by connecting the CD3 antigen in the receptor complex with the CD19 surface antigen on both benign and malignant B cells, activating inflammatory cytokine release and T-cell proliferation resulting in apoptosis of CD19+ cells. It is effective in patients with Philadelphia negative B-cell precursor ALL. Common side effects include pyrexia, neutropenia, infections, and infusion-related reactions. Patients should receive dexamethasone before infusion and when restarting an infusion if interrupted for more than 4 hours. Rare but serious side effects include CRS and neurologic toxicity, such as paresthesia, confusion, dizziness, and tremor. Thus, patients are typically hospitalized for the first cycle and first 2 days of the second cycle. Medication errors can occur when preparing and administering blinatumomab because preparation instructions are more complicated than most other IV drugs. Doses are based on weight, dose, and duration of infusion. Additionally, specific instructions for use of an IV solution stabilizer are provided rather than mixing with the drug for reconstitution and the volume for infusion.

▶ Cetuximab, Necitumumab, and Panitumumab

Cetuximab is a chimeric antibody that binds to the EGFR to block its stimulation. Panitumumab binds to the EGFR to prevent receptor autophosphorylation and activation of receptor-associated kinases, which results in inhibition of cell growth and induction of apoptosis. Necitumumab is an anti-EGFR recombinant human monoclonal antibody. Cetuximab has shown clinical activity in the treatment of colorectal and head and neck cancers, necitumumab in non–small cell lung cancer, and panitumumab in colorectal cancers. Tumors that have *RAS* mutations do not respond to treatment with cetuximab or panitumumab; therefore, tumors should be tested for *RAS* mutations before initiating therapy. An acne-like rash may appear on the face and upper torso 1 to 3 weeks after the start of therapy. Preventive therapies with topical corticosteroids with moisturizer, sunscreen, and oral doxycycline are recommended. Other side effects include hypersensitivity reactions, fever, nausea and vomiting, and interstitial lung disease. Electrolyte disturbances, such as hypomagnesemia and hypocalcemia, can occur; these are more common with necitumumab and panitumumab.

▶ *Daratumumab and Isatuximab*

Daratumumab and isatuximab are monoclonal antibodies to the CD38 receptor, highly expressed on myeloma cells and weakly on other hematopoietic stem cells. They are used in patients with MM. Infusion-related reactions are common so patients must be pretreated with acetaminophen, an antihistamine, and IV methylprednisolone. Additionally, with daratumumab, an oral corticosteroid is administered for each of the 2 days following infusion to prevent delayed reactions. Also, these drugs also interact with cross matching and red blood cell antibody screening, by causing a positive indirect Coombs test that can persist for 6 months after discontinuation of therapy. Thus, patients should be typed and screened before therapy, and blood banks should be informed when a patient has received either of these drugs.

▶ *Elotuzumab*

Elotuzumab is a humanized recombinant monoclonal antibody that specifically targets signaling lymphocytic activation molecule family member 7 protein. It works by directly activating natural killer cells to mediate the killing of myeloma cells through antibody-dependent cellular cytotoxicity (ADCC). Premedications to prevent infusion-related reactions should include dexamethasone, H_1 blocker, H_2 blocker, and acetaminophen. The most common side effects are fatigue, diarrhea, pyrexia, constipation, and cough.

▶ *Obinutuzumab, Ofatumumab, and Rituximab*

Obinutuzumab, ofatumumab, and rituximab are monoclonal antibodies to the CD20 receptor expressed on the surface of B lymphocytes; the presence of the antibody is determined during flow cytometry of the tumor cells. Cell death results from ADCC. All of these drugs have shown clinical activity in the treatment of B-cell lymphomas that are CD20 positive. Side effects include infusion-related reactions, hypotension, fevers, chills, rash, headache, and mild nausea and vomiting. Premedication with acetaminophen and an antihistamine is recommended for rituximab to minimize the first-dose infusion reaction. Acetaminophen, an antihistamine, and a glucocorticoid are administered prior to obinutuzumab and ofatumumab. In patients with extensive disease, prevention of tumor lysis syndrome is also recommended. Serious adverse events, including fatal infections, progressive multifocal leukoencephalopathy, and reactivation of hepatitis B, have been reported. Thus, all patients should be tested for hepatitis B and treated before therapy commences.

▶ *Pertuzumab, Trastuzumab, and Trastuzumab/Hyaluronidase*

Pertuzumab and trastuzumab-based products are humanized monoclonal antibodies directed against human epidermal receptor 2 (HER-2). When compared to trastuzumab products, pertuzumab recognizes different extracellular epitopes, binds uniquely, which causes structural changes and, therefore, interrupts receptor dimerization. These differences were thought to be able to provide greater inhibition of HER-2 when compared to trastuzumab, but this has not been proven to be the case. Cancer tissue must be tested for the presence of HER-2 because patients who do not express HER-2 do not respond to trastuzumab. Trastuzumab hyaluronidase is trastuzumab combined with an enzyme hyaluronidase-oysk that allows the drug to be delivered subcutaneously, reducing potential for infusion-related reactions and shorter administration. Trastuzumab-products and pertuzumab are used for certain patients with HER-2 positive breast cancers; trastuzumab (but not all products) can also be used in other solid tumors that are HER-2 positive (eg, gastric cancer). Trastuzumab products are not interchangeable and may have different dose, schedules, and indications.

Severe congestive heart failure may occur with concurrent HER-2 monoclonal antibody and anthracycline administration. Cardiac toxicity may be seen when the drug is administered months after anthracycline administration, so patients must be counseled on the signs and symptoms of heart failure. A common side effect associated with trastuzumab is a first-dose infusion-related reaction which includes chills. The patient may be given acetaminophen and diphenhydramine and/or the infusion may be slowed. Other side effects that are rare include hypersensitivity reactions, abnormal liver function tests, and pulmonary reactions.[32] Pertuzumab has similar adverse effects as trastuzumab. When used in combination with trastuzumab, it does not appear to increase the incidence of cardiac toxicity. A more detailed discussion of the use of trastuzumab products and pertuzumab in breast cancer can be found in Chapter 89.

Antibody Conjugates

Antibody conjugates contain both an antibody and either a drug or radioisotope. In many cases, the antibody is used as a drug vehicle to deliver an anticancer agent either an antineoplastic agent or the radioisotope. In some cases, a linking agent is also used to link the antibody and anticancer drug. Antibody–drug conjugates are often referred to as ADCs.

▶ *Ado-Trastuzumab Emtansine (Trastuzumab Emtansine) and Fam-Trastuzumab Deruxtecan*

Ado-trastuzumab emtansine combines trastuzumab and the anticancer agent emtansine (a maytansine derivative). Fam-trastuzumab deruxtecan is composed of fam-trastuzumab (which has same basic structure of trastuzumab), a topoisomerase I inhibitor exatecan derivative (DXd), and a compound that links the drugs, deruxtecan. The most common serious adverse effect with ado-trastuzumab emtansine was thrombocytopenia. The platelet nadir usually occurs about 7 days after treatment and recovers within a week. Other side effects are similar to trastuzumab products. See more detail in Chapter 89.

▶ *Belantamab Mafodotin*

Belantamab mafodotin is composed of the monoclonal antibody belantamab directed against B-cell maturation antigen (BMCA) and the conjugate mafodotin, an auristatin analogue and microtubule inhibitor monomethyl auristatin phenylalanine (MMAF) that has antineoplastic activity. It is used in MM. It has boxed warning regarding corneal epithelium changes including severe vision loss and corneal ulcer. Ophthalmologic exams are, therefore, required at baseline and throughout therapy. Additionally infusion-related reactions and fatigue may occur.

▶ Brentuximab Vedotin

Brentuximab vedotin is a CD30-directed antibody, a microtubule disrupting agent called monomethyl auristatin E (MMAE), and a protease-cleavable linker that covalently attaches MMAE to the antibody. It is reported that the cytotoxic activity is a result of the binding of the ADC to CD30-expressing cells followed by internalization of the ADC–CD30 complex, and then proteolytic cleavage and release of MMAE into the cell. Binding of MMAE to tubulin disrupts the microtubule network, resulting in cell cycle arrest and apoptosis. This IV agent is indicated for some Hodgkin lymphoma and non-Hodgkin lymphoma patients. In vitro data suggests that MMAE is a substrate and an inhibitor of CYP3A4/5; therefore, patients need to be monitored for drug–drug interactions. The most common adverse effects are neutropenia, peripheral neuropathy, fatigue, nausea and vomiting, diarrhea, anemia, thrombocytopenia, and upper respiratory infection.

▶ Ibritumomab Tiuxetan

Ibritumomab tiuxetan, a "*hot antibody*," is linked to yttrium and binds to the CD20 receptor of B lymphocytes. Hematologic toxicity may occur several weeks after administration and may take weeks to resolve.

▶ Polatuzumab Vedotin

Polatuzumab vedotin is an ADC directed against CD79B via a proteas-cleavable peptide linker to MMAE, an auristatin derivative and potent microtubule inhibitor. This drug is used for diffuse large B-cell lymphoma and is associated with myelosuppression, peripheral neuropathy, serious infections, and infusion-related reactions. Thus, an antihistamine and antipyretic are used for premedications and patients should receive prophylaxis for herpes virus and PJP.

▶ Sacituzumab Govitecan

Sacituzumab govitecan is an antibody against tumor-associated calcium signal transducer 2 linked to an irinotecan metabolite, SN-38. This drug is indicated for metastatic triple-negative breast cancer. It is has boxed warnings for neutropenia and severe diarrhea. It is associated with nausea, anorexia, fatigue, and infusion-related reactions. Prior to each dose, premedicate with antipyretics and H_1/H_2 antagonists; corticosteroids may be administered if an infusion-related reaction occurred with a prior dose that required premedications. Patients with UGT1A1*28 deficiency are at an increased risk of neutropenia and other adverse events.

Checkpoint Inhibitors

The immune system is in a continual state of balance between tolerating "normal" tissue and attacking foreign substances. Immunological tolerance is regulated by immune cells, suppressive cytokines, and immune checkpoint pathways.[27] Immune checkpoints become involved following immune activation, creating an inhibitory feedback loop to reduce involvement of normal tissues. Inhibitors of the immune checkpoints act by inhibiting key regulatory steps, promoting activation and proliferation of T cells to induce tumor infiltration and regression. Tumor responses to checkpoint inhibitors differ from those observed with other anticancer therapies. Responses can be seen long after the start of treatment, and pseudoprogression can be seen immediately after starting therapy which, instead of representing a tumor progression, can represent inflammation only within the tumor area. Checkpoint inhibitors are now approved for use not only in many solid tumors but also in some hematologic tumors and can be administered alone or in combination with each other, chemotherapy and targeted therapies.

Adverse effects of checkpoint inhibitors are related to their effect on the immune system, whereby they attack normal cells as well. This can result in severe and fatal immune-mediated adverse reactions, including enterocolitis, hepatitis, toxic epidermal necrolysis, neuropathy, pneumonitis, and endocrine abnormalities. Thus a physical examination and review of systems is important to quickly identify and treat toxicity. Complete blood counts (CBCs) with differentials, comprehensive metabolic panel, and liver function tests should be performed at baseline and cortisol and thyroid function tests periodically. Patients should be monitored for symptoms of inflammatory responses (eg, diarrhea as early sign of colitis, shortness of breath as early sign of pneumonitis). These symptoms can occur during treatment or weeks to months after discontinuation of the drug. If any of these reactions occur, treatment should be initiated with systemic corticosteroids, which are tapered once symptoms improve, and the drug should be held until symptoms resolve. Severe toxicities require permanent discontinuation. Unlike other anticancer agents, dose reductions are not used as a toxicity management strategy with checkpoint inhibitors. Typically, these side effects can be more severe with the cytotoxic T lymphocyte–associated antigen 4 (CTLA-4) inhibitor than PD-1 or PD-ligand (PD-L)-1 inhibitors. NCCN publishes guidelines for management of immunotherapy toxicities and more details can be found in the Supportive Care (Chapter 99).[25]

▶ Ipilimumab

Ipilimumab is a recombinant, human monoclonal antibody that binds to the CTLA-4, which is a molecule on T cells that causes a suppression of the immune response. CTLA-4 is a negative regulator of T-cell activation. Ipilimumab binds to CTLA-4 and blocks the interaction of CTLA-4 with its ligands. This blockage has been reported to enhance T-cell activation and proliferation. The antitumor effects appear to be T-cell–mediated immune responses and are the highest with this drug of all the available checkpoint inhibitors.

▶ Cemiplimab, Nivolumab, and Pembrolizumab

Cemiplimab, nivolumab, and pembrolizumab are human monoclonal antibodies that block the interaction of the binding to PD-1 and its ligands, PD-L1 and PD-L2. Cemiplimab is approved for patients with cutaneous squamous cell carcinoma. Both nivolumab and pembrolizumab are active in many solid and some hematologic tumors. Pembrolizumab is also the first monoclonal antibody to be approved as a tumor agnostic therapy. That is, it is approved for patients with any cancer that have high microsatellite instability or high mutational tumor burden. Side effects are much less common with PD-1 inhibitors compared with the CTLA-4 inhibitor ipilimumab.

▶ Atezolizumab, Avelumab, and Durvalumab

Atezolizumab, avelumab, and durvalumab are recombinant, human monoclonal antibodies that bind PD-L1 and block interaction with the PD-1 receptors. These drugs are active in many solid tumors. Side effects are much less common with PD-L1 inhibitors compared with the CTLA-4 inhibitor ipilimumab.

Tyrosine Kinase Inhibitors (TKI)

More than 100 different types of tyrosine kinases are present in the body. TKIs have been developed to block either several or a specific tyrosine kinase (see Table 88–6). They are used to treat solid tumors, leukemias, and lymphomas and can be used as alone or in combination with IV chemotherapy, surgery, and/or radiation. Some are continuously administered until disease progression occurs or intolerance develops whereas others are given cyclically (eg, 2 weeks on, 1 week off; then repeat). Side effects often limit use if uncontrolled and typically are different than those observed from traditional chemotherapy or immunotherapy. Drug interactions are common as many of these drugs are metabolized through the CYP450 and P-glycoprotein systems and can have decreased concentrations in the presence of antacids, H_2 blockers, and/or proton pump inhibitors.

▸ *Anaplastic Lymphoma Kinase (ALK) Inhibitors (Alectinib, Brigatinib, Ceritinib, Crizotinib, and Lorlatinib)*

These small molecules primarily inhibit anaplastic lymphoma kinase (ALK) and often will inhibit others such as mesenchymal epithelial transition growth factor *c-MET, (*crizotinib), Ret proto-oncogene (RET), (alectinib); or insulin-like growth factor 1 receptor, insulin receptor, and ROS proto-oncogene 1 (ROS1), (brigatinib and lorlatinib). These orally available agents are approved for the treatment of NSCLC, that is ALK positive (about 2%–7% of NSCLC patients) as detected by an FDA-approved test. Adverse effects include mild GI symptoms and elevated liver function tests. Visual changes, pulmonary disease, and QTc prolongation can also occur as well as creatine kinase elevations specifically with alectinib. Lorlatinib is associated with CNS effects such as changes in cognitive function, mood, sleep, and seizures.

▸ *B-cell Lymphoma 2 (Bcl-2) Inhibitor (Venetoclax)*

Venetoclax selectively inhibits the anti-apoptotic protein Bcl-2, which is over-expressed in CLL and AML, thus restoring the apoptotic process. This drug can work quickly and put patients at risk for tumor lysis syndrome. Thus, the dose is escalated slowly with tumor lysis monitoring and prophylaxis required. A reduced renal function increases the risk of tumor lysis syndrome. Myelosuppression, nausea, and diarrhea can occur.

▸ *BCR-ABL TKIs (Bosutinib, Dasatinib, Imatinib, Nilotinib, and Ponatinib)*

Imatinib was the first FDA-approved TKI. Imatinib inhibits phosphorylation during cell proliferation. The drug was designed to block the breakpoint cluster region tyrosine kinase (BCR-ABL) produced by the Philadelphia chromosome associated with CML and ALL. Imatinib also has shown activity against GI stromal tumors (GIST) that are positive for c-kit (CD117). Imatinib is usually well tolerated, but common adverse effects include myelosuppression, rash, GI upset, edema, fatigue, arthralgias, myalgias, and headaches. A cumulative cardiotoxicity is a serious but rare adverse effect; therefore, it is recommended to closely monitor patients with preexisting cardiac conditions.

Advanced generation BCR-ABL TKIs are more potent than imatinib and can overcome most BCR-ABL mutations that lead to imatinib resistance. Bosutinib, dasatinib, and nilotinib are second-generation BCR-ABL TKIs and are used frontline in the treatment of CML and in CML with resistance or intolerance to imatinib. Side effects of dasatinib and nilotinib are similar to imatinib and include myelosuppression, nausea and vomiting, headache, fluid retention, and hypocalcemia. Pleural effusions have been reported with dasatinib and imatinib but not with nilotinib. QTc prolongation can occur with dasatinib and nilotinib. Abnormalities in indirect bilirubin have been reported with nilotinib and is more common in patients with (TA)7/(TA)7 genotype (*UGT1A1*28*).[28] Bosutinib appears to have a milder side effect profile than other TKIs, with GI disturbances and rash being most common.

Ponatinib is a third-generation multikinase inhibitor and the only advanced generation TKI that overcomes the *T315I* mutation. The serious adverse effects thrombosis, hepatotoxicity (rare), and death (rare) are included as boxed warnings. Less serious adverse effects include abdominal pain, dry skin, and rash.

▸ *BRAF Inhibitors (Dabrafenib, Encorafenib, and Vemurafenib)*

Dabrafenib, encorafenib, and vemurafenib are inhibitors of *BRAF* kinases. They most often are used to treat melanoma and also some colon cancers that have *BRAF V600E* mutations. Common adverse effects of BRAF inhibitors include arthralgias, alopecia, GI symptoms, and fatigue. Other adverse effects of vemurafenib include rash, keratoacanthoma or squamous cell cancer, and photosensitivity. Adverse effects associated with dabrafenib include headache, palmar–plantar erythrodysesthesia syndrome, elevated liver enzymes, pyrexia, and papilloma. Encorafenib is associated with electrolyte disturbances, including hyperglycemia and increased serum creatinine.

▸ *Bruton's Tyrosine Kinase (BTK) Inhibitors (Acalabrutinib, Ibrutinib, and Zanubrutinib)*

Bruton's tyrosine kinase (BTK) is an integral component of the B-cell receptor. Constitutive activation of B-cell receptor signaling allows the survival of malignant B cells. BTK inhibitors decrease malignant B-cell proliferation and survival and are used in CLL and some types of non-Hodgkin lymphomas. A noninfectious, transient lymphocytosis should be expected and can last for weeks but does not signify disease progression. Myelosuppression and mild GI toxicities are the most common adverse effects. Infection risk is high; hepatitis B reactivation can occur, thus testing at baseline for hepatitis B is recommended. Secondary cancers, primarily skin malignancies, have also been reported. BTK inhibitors can increase the risk of bleeding, particularly in patients receiving antiplatelet or anticoagulant medications. Additionally, cardiac toxicity, including new-onset atrial fibrillation, hypertension, and ventricular tachyarrhythmias can, occur but are more frequent with ibrutinib. Acalabrutinib is associated with headaches that are typically resolved after 1 to 2 months of therapy and can be managed with acetaminophen and caffeine. Zanubrutinib is associated with rashes.

▸ *Cyclin-Dependent Kinase (CDK) Inhibitors (Abemaciclib, Palbociclib, and Ribociclib)*

Abemaciclib, palbociclib, and ribociclib all inhibit cyclin-dependent kinases (CDKs) 4 and 6, which prevent phosphorylation and subsequent inactivation of the retinoblastoma tumor suppressor protein, ultimately causing cell cycle arrest and inhibiting cancer cell proliferation. Each of the available CDK4/6 inhibitors is used in the treatment of postmenopausal women with hormone receptor positive but HER-2 negative breast cancer. Palbociclib and ribociclib are administered daily for 21 days, followed by 7 days off, whereas abemaciclib is administered daily. Common side effects include neutropenia, GI toxicities, and hair loss. Rarely, abemaciclib is associated with venous thromboembolism, ribociclib with QTc prolongation, and both with hepatotoxicity.

▶ EGFR Pathway Inhibitors (Afatinib, Dacomitinib, Erlotinib, Gefitinib, Lapatinib, Neratinib, Osimertinib, and Tucatinib)

Patients with NSCLC in which the tumors have mutations in exon 19 and/or 21 in the EGFR pathway will likely respond to EGFR TKIs such as afatinib, dacomitinib, and erlotinib. Those with EGFR *T790M* mutations will likely respond to osimertinib. These agents are believed to inhibit the intracellular phosphorylation of the EGFR. Food increases bioavailability to almost 100% but is variable; experts recommend administering erlotinib on an empty stomach. Smoking increases the clearance of erlotinib by 24%, which may result in treatment failure and different doses are used for smokers versus nonsmokers.[29] Side effects of EGFR inhibitors include acneiform rash, diarrhea, dry skin, fatigue, anorexia, pruritus, conjunctivitis, and rarely interstitial lung disease. Diarrhea and rash are highest among afatinib and dacomitinib.

Lapatinib, neratinib, and tucatinib inhibit the intracellular kinase domains of both EGFR and HER-2 and have been shown to retain activity against breast cancer cells that have become resistant to trastuzumab. These are indicated for the treatment of patients with breast cancer whose tumors overexpress HER-2. Common side effects include diarrhea, nausea/vomiting, fatigue, and HFS.

▶ Fibroblast Growth Factor Receptor (FGFR) (Erdafitinib and Pemigatinib)

Fibroblast growth factor receptor (FGFR) inhibitors bind to and inhibit FGFR, which may be overexpressed on certain tumor cells. Erdafitinib is indicated for urothelial carcinoma patients with FGFR-2 or -3 genetic alterations; whereas pemigatinib is indicated for those with cholangiocarcinoma and an FGFR-2 fusion or other gene rearrangement. FGFR inhibitors can cause hyperphosphatemia, stomatitis, fatigue, dry mouth/skin, alopecia, onycholysis, liver function enzyme elevations and rarely ocular disorders such as serous retinopathy/retinal pigment epithelial detachment.

▶ Hedgehog Inhibitors (Glasdegib, Sonidegib, and Vismodegib)

The Hedgehog pathway is a signaling pathway that regulates self-renewal and differentiation of cells. It is abnormally activated in basal cell carcinoma, medulloblastoma, and leukemia. These inhibitors bind to smoothened (SMO), a transmembrane protein, and prevents downstream signaling and activation of the Hedgehog pathway thus preventing tumor growth. Glasdegib is indicated for AML treatment and sonidegib and vismodegib are indicated for basal cell carcinoma. Because the Hedgehog pathway is essential for embryogenesis, these drugs have boxed warnings for severe birth defects and embryo–fetal death and have strict recommendations for contraception for both males and females and pregnancy tests within 7 days of starting therapy. Patients are also advised to not donate blood during and for 30 days to 24 months following the last dose, depending on the drug. The most common adverse effects of sonidegib and vismodegib include muscle spasms, alopecia, dysgeusia, weight loss, fatigue, and GI toxicities. Glasdegib is also associated with myelosuppression, GI toxicities, edema, and dyspnea and may cause QTc prolongation. Sonidegib can increase serum creatine kinase levels, leading to severe musculoskeletal events.

▶ Isocitrate Dehydrogenase (IDH) Inhibitors (Enasidenib and Ivosidenib)

Isocitrate dehydrogenase (IDH) enzymes are part of the citric acid cycle, which is responsible for cellular respiration. In cancer, IDH1 and IDH2 are recurrently mutated and produce 2-hydroxglutarate that alters DNA methylate and leads to the inhibition of cellular differentiation. Enasidenib is a potent selective inhibitor of mutant IDH2 and ivosidenib is a selective reversible inhibitor of mutant IDH1 and are used for IDH-mutated AML. The most common adverse events include hyperbilirubinemia without concurrent transaminase elevation. Enasidenib is associated with nausea and vomiting and requires a prophylactic antiemetic and can cause leukocytosis and tumor lysis syndrome. Ivosidenib is associated with fatigue, noninfectious leukocytosis, arthralgia, diarrhea, and QTc prolongation.

▶ Mitogen-Activated Extracellular Kinases (MEK) Inhibitors (Binimetinib, Cobimetinib, Selumetinib, and Trametinib)

Binimetinib, cobimetinib, and trametinib are reversible inhibitor of mitogen-activated extracellular kinases (MEK)-1 and MEK-2 and are active against *BRAF V600*-mutated forms of BRAF kinases in melanoma cells. They most often are used in combination with BRAF inhibitors for malignant melanoma. Rash, diarrhea, fatigue, acneiform dermatitis, and peripheral and lymph edema are commonly reported. Cardiomyopathy (defined as heart failure) and bleeding have also been reported. Selumetinib is approved for a pediatric with neurofibromatosis type 1. Most common adverse effects are nausea, vomiting, diarrhea, rash, dry skin, and fatigue.

▶ Mammalian Target of Rapamycin (mTOR) Inhibitors: Temsirolimus and Everolimus

The mammalian target of rapamycin (mTOR) is a downstream mediator in the phosphatidylinositol 3-kinase/Akt signaling pathway that controls translation of proteins that regulate not only cell growth and proliferation but also angiogenesis and cell survival. The mTOR is an intracellular component that stimulates protein synthesis by phosphorylating translation regulators and contributes to protein degradation and angiogenesis.

Temsirolimus is approved for the treatment of advanced kidney cancer. Temsirolimus and its metabolite sirolimus are substrates of the CYP3A4/5 isoenzyme system. The primary side effects of temsirolimus include mucositis, diarrhea, maculopapular rash, nausea, leucopenia, thrombocytopenia, and hyperglycemia. Noninfectious pneumonitis can occur and must be identified immediately for best outcomes.

Everolimus is an oral inhibitor of mTOR that is approved for the treatment of patients with advanced kidney cancer, breast cancer, and neuroendocrine tumors. Drug interactions and adverse reactions are similar to those of temsirolimus.

▶ Multikinase Inhibitors (Axitinib, Cabozantinib, Sorafenib, Sunitinib, and Pazopanib)

Multikinase inhibitors inhibit multiple tyrosine kinases and are used for many different cancers. A full list of available multikinase inhibitors is found in Table 88–6. Some of the more common ones are described here. Sorafenib is a multikinase inhibitor that inhibits both intracellular and extracellular kinases and is used in the treatment of hepatic, kidney, and thyroid cancers. The primary side effects of sorafenib include rash, diarrhea, pruritus, and elevations in serum lipase. Hand–foot skin reaction (HFSR) can also occur with those drugs that affect the VEGF receptor. HFSR differs than HFS in that it initially develops as erythema and soreness, progressing to blisters, and eventually hyperkeratosis.

Cabozantinib and pazopanib both primarily inhibit VEGF receptor-1 (VEGFR)-1, VEGFR-2, VEGFR-3, and several other tyrosine kinases. Cabozantinib is available in two dosage forms: tablets and capsules. The tablet formulation is used for patients with advanced kidney cancer, whereas the capsules are a larger dose for patients with medullary thyroid cancer. Pazopanib is used to treat advanced kidney cancer and sarcomas. Common side effects of these drugs are diarrhea, nausea, anorexia, HFSR syndrome, hypertension, and fatigue. Pazopanib also is associated with hair color changes. Serious toxicities that have been observed are fatal hepatotoxicity, prolonged QTc intervals and torsade's de pointes, hemorrhagic events, arterial thrombotic events, GI perforation, and proteinuria.

Regorafenib is another small molecule inhibitor of multiple membrane-bound and intracellular kinases used in the treatment of metastatic colorectal cancer and GI stromal tumor. The proposed mechanism of action is through inhibition of VEGFR involved in angiogenesis. GI effects, hypertension, mucositis, infection, rash, and fever are commonly occurring adverse effects. Hepatotoxicity is listed as a black-box warning; therefore, hepatic function should be monitored closely. It is an orally administered agent given for the first 21 days per 28-day cycle and should be taken with a low-fat breakfast (30 g or less).

▶ *Neurotrophic Tyrosine Receptor Kinase (NTRK) (Entrectinib and Larotrectinib)*

Neurotrophic tyrosine receptor kinase (NTRK) inhibitors are the first oral anticancer agents approved pan-tumor, meaning they are used to treat a specific genetic mutation rather than a tumor type. Both entrectinib and larotrectinib are used adults and pediatric patients with solid tumors that have a NTRK gene fusion without a known acquired resistance. Entrectinib is also approved for *ROS*1-positive NSCLC. The most common adverse reactions include fatigue, nausea/vomiting, diarrhea, constipation, and dizziness. Elevations in transaminases may occur. Rarely, entrectinib is associated with reductions in left ventricular ejection fraction (LVEF), QTc prolongation, vision disorders, hyperuricemia, and skeletal fractures.

▶ *Phosphoinositide 3-Kinase (PI3-K) Inhibitors (Alpelisib, Copanlisib, Duvelisib, and Idelalisib)*

Phosphoinositide 3-kinase (PI3-K), an essential lipid kinase, is the target of inhibition for alpelisib, copanlisib, duvelisib, and idelalisib. Alpelisib is indicated for breast cancer patients with a PI3KCA mutation and the other drugs are used in the treatment of follicular lymphoma and CLL. Adverse effects associated with copanlisib are hyperglycemia, hematologic abnormalities, fatigue, diarrhea, and hypertension. Duvelisib is associated with hepatotoxicity, diarrhea, cutaneous reactions, and myelosuppression. Idelalisib causes GI disturbances, rash, hematological side effects, fatigue, and musculoskeletal pain. Idelalisib caries boxed warnings for hepatotoxicity, colitis, pneumonitis, infections, and intestinal perforation. Because the PI3-K pathway regulates the immune system, PI3K inhibitors result in immunosuppression, placing patients receiving these medications at risk for immunocompromising infections such as PJP and cytomegalovirus; thus close monitoring and consideration of prophylactic antibacterials and antivirals is warranted.

▶ *Poly ADP Ribose Polymerase (PARP) Inhibitors (Niraparib, Olaparib, and Rucaparib)*

PARP enzymes are involved in normal cellular function, including DNA transcription and repair. PARP inhibitors prevent DNA repair, allow apoptosis to occur and inhibit tumor growth. Niraparib is used to treat ovarian, fallopian tube, or peritoneal cancer; olaparib is used to treat some breast, ovarian, pancreatic, and prostate cancers, and rucaparib is used to treat some ovarian and prostate cancers. Common side effects include myelosuppressive side effects, GI toxicities, fatigue, upper respiratory tract infections, and arthralgias and myalgias. Rarely, patients can develop MDS or AML and pneumonitis. Niraparib also causes hypertension and patients must undergo heart rate (HR) and blood pressure (BP) monitoring monthly for the first year.

▶ *Proteasome Inhibitors (Bortezomib, Carfilzomib, and Ixazomib)*

The proteasome is an enzyme complex that exists in all cells and plays an important role in degrading proteins that control the cell cycle. When the proteasome is inhibited, the numerous pathways that are necessary for the growth and survival of cancer cells are disrupted. Bortezomib specifically inhibits the 26S proteasome, which is a large protein complex that degrades ubiquitinated proteins. This pathway plays an essential role in regulating the intracellular concentration of specific proteins, causing the cells to maintain homeostasis. Inhibition of the 26S proteasome prevents this from occuring, ultimately causing a disruption in the homeostasis and cell death. Both carfilzomib and ixazomib inhibit 20S proteasome, which is the proteolytic core with the 26S proteasome.

Bortezomib is approved for the treatment of MM and mantle cell lymphoma. It is administered either as an IV or SC injection. The most commonly reported adverse effects are asthenia, GI disturbances (nausea, diarrhea, decreased appetite, constipation, vomiting), thrombocytopenia, peripheral neuropathy, anemia, headache, insomnia, and edema. Peripheral neuropathy is much lower with the SC injection. Prophylactic anticoagulation is not routinely required. Reactivation of varicella zoster infection is also common with bortezomib, and antiviral prophylaxis with acyclovir should be considered.

Carfilzomib and ixazomib are second-generation proteasome inhibitors. Carfilzomib is administered by IV, whereas ixazomib is a capsule that should be taken on an empty stomach. Both of these drugs used in the treatment of refractory cases of MM and have similar but fewer side effects compared with bortezomib.

▶ *RET Inhibitors (Pralsetinib and Selpercatinib)*

RET inhibitors inhibit wild-type RET and oncogenic RET fusions and mutations that are found in 1%–2% of NSCLCs and some thyroid cancers. These drugs are commonly associated with elevations in transaminases, myelosuppression, fatigue, and hypertension. Impairment of wound healing and hemorrhage can occur. Optimization of hypertension is recommended before initiation. Less commonly selpercatinib can cause QTc prolongation and hypersensitivity. Pralsetinib can cause interstitial lung disease.

▶ *Selective Inhibitor of Nuclear Export Antagonist (Selinexor)*

Selinexor is an orally available, small molecular inhibitor of chromosome region maintenance 1 protein, also known as exportin 1 (XOP1). Essentially, selinexor inhibits tumor suppressor proteins, growth regulators, and mRNA of oncogenic proteins, resulting in accumulation of these cell cycle arrest and cancer apoptosis. It is used in non-Hodgkin lymphoma and MM. Common adverse events include myelosuppression, GI toxicity including nausea and vomiting that requires prophylactic antiemetics, hyponatremia, dizziness, and mental status changes.

Hormonal Therapies

Hormonal or endocrine therapies have activity in the treatment of cancers whose growth is affected by gonadal hormonal control. Hormonal treatments either block or decrease the production of endogenous hormones. These agents are covered extensively in Chapters 89 and 92, in the breast and prostate cancer chapters.

▶ Antiandrogens (Bicalutamide, Flutamide, and Nilutamide)

The antiandrogens block androgen receptors (ARs) and inhibit the action of testosterone and dihydrotestosterone in prostate cancer cells. Side effects common to these agents are hot flashes, gynecomastia, and decreased libido. Flutamide tends to be associated with more diarrhea and requires three times daily administration, whereas bicalutamide is dosed once daily. Nilutamide may cause interstitial pneumonia and is associated with the visual disturbance of delayed adaptation to darkness.

▶ Pure AR Antagonists (Apalutamide, Darolutamide, and Enzalutamide)

Pure antagonists competitively inhibit androgen binding to ARs and AR nuclear translocation and coactivator recruitment of the ligand-receptor complex. All three are indicated for non-metastatic castrate-resistant prostate cancer; both apalutamide and enzalutamide are indicated for the treatment of metastatic hormone sensitive prostate cancer; and enzalutamide is also approved for metastatic castration-resistant prostate cancer. The most common side effect of these therapies is fatigue and hypertension, but overall are they well tolerated. Apalutamide is also associated with rash and hypothyroidism.

▶ Luteinizing Hormone–Releasing Hormone Agonists (Goserelin and Leuprolide)

Initially, luteinizing hormone–releasing hormone (LHRH) agonists increase levels of luteinizing hormone and follicle-stimulating hormone, but testosterone and estrogen levels are decreased because of continuous negative-feedback inhibition. Major side effects are testicular atrophy, decreased libido, gynecomastia, and hot flashes. Goserelin is injected as a pellet under the skin; therefore, SC injection of lidocaine around the injection site before administration helps to decrease the pain associated with administration. Numerous dosage forms are available for leuprolide with varying strengths and dosing intervals. Antiandrogens may be administered during initial therapy to decrease symptoms of tumor flare (eg, bone pain and urinary tract obstruction).

▶ Gonadotropin-Releasing Hormone Antagonist (Degarelix)

Degarelix is a gonadotropin-releasing hormone (GnRH) receptor antagonist that reversibly binds to the pituitary GnRH receptors, thereby reducing the release of gonadotropins and consequently testosterone. Degarelix is indicated for the treatment of advanced prostate cancer. Adverse effects include hot flashes, injection site reactions, and an increase in liver enzymes. An advantage of degarelix over LHRH agonists is the lack of the tumor flare.[30]

▶ Abiraterone

Abiraterone is an orally available androgen biosynthesis inhibitor that inhibits 17α-hydroxylase/C17,20-lyase (CYP17), which is expressed in testicular, adrenal, and prostatic tumor tissues. Abiraterone is indicated in combination with prednisone for the treatment of metastatic prostate cancer. Two formulations are available: abiraterone acetate and micronized abiraterone. Both the dose and the administration are different between formulations. The conventional formulation of abiraterone is taken on an empty stomach; however, the micronized formulation can be taken without respect to food. Adverse effects include hypokalemia, edema, muscle discomfort, fatigue, hot flashes, nocturia, urinary frequency, and hypertension.

▶ Aromatase Inhibitors (AIs) (Anastrozole, Exemestane, Letrozole)

Three AIs are currently available: anastrozole, letrozole, and exemestane. All three agents work by inhibiting aromatase, which prevents the conversion of androstenedione to estrone and testosterone to estradiol in adipose tissue, which is the primary source of estrogens in post menopausal women. All three agents are used to treat breast cancer in postmenopausal women and are considered interchangeable in terms of activity. When compared to tamoxifen, there are less endometrial and uterine cancers, vaginal bleeding, and thrombosis with AI therapy. Common adverse effects associated with the AI therapy include hot flashes and arthralgias. Serious adverse effects include osteoporosis, skeletal-related events, and atherosclerotic cardiovascular disease. More information on the pharmacology and clinical use of AI therapy can be found in Chapter 89.

▶ Antiestrogens (Fulvestrant, Raloxifene, and Tamoxifen)

Antiestrogens bind to ERs and block the effect of estrogen on tissue. Two classes of antiestrogens exist: SERMs (tamoxifen, raloxifene) and selective estrogen-receptor downregulators (SERDs, fulvestrant). SERDs were developed in an effort to eliminate the unwanted estrogenic side effects from the SERMs. Tamoxifen is used for the treatment of ER positive premenopausal or postmenopausal metastatic hormone receptor–positive breast cancer, as adjuvant and primary treatment of breast cancer, and in the prevention of breast cancer in high-risk women. The agent has a beneficial effect on bone density and the lipid profile. Unwanted side effects include hot flashes, fluid retention, and mood swings. Thrombosis, endometrial and uterine cancer, corneal changes, and cataracts are harmful adverse effects that occur more frequently with this agent. Although uncommon, there is a disease/tumor flare that can occur during the initiation of therapy in metastatic breast cancer patients with bone metastases. Because tamoxifen is a substrate of CYP3A4, decreased tamoxifen levels have occurred with use of St. John's wort and rifampin. Tamoxifen is also a substrate for CYP450 2D6 and evidence suggests that those who are *CYP2D6*4/*4* may have a poorer response and more toxicity with tamoxifen.[31] Routine pharmacogenomics screening of these patients is not currently recommended. Significant drug interactions exist and drug–drug interactions affecting this enzyme should be avoided if possible.

Raloxifene is another SERM and is used for the treatment of osteoporosis in postmenopausal women and is the

Patient Encounter 1, Part 3

The patient has progressed following therapy with initial treatment with docetaxel and subsequently was found to have a BRCA1 mutation. He now will be receiving a new prescription for olaparib 300 mg orally, twice daily.

What education and training should be provided to the patient to ensure his understanding of safe handling procedures as well as thorough knowledge of proper administration?

How should the patient be instructed to take this medication, in regards to meals or the time of day?

chemopreventive agent of choice for the prevention of breast cancer in high-risk women. When compared head to head with tamoxifen for breast cancer prevention, it was demonstrated to have equal efficacy with less toxicity. Raloxifene was not studied in premenopausal women; therefore, tamoxifen is still the preventative agent of choice in these women. Hot flashes, arthralgias, and peripheral edema occur frequently with raloxifene, but thrombosis and endometrial cancer is less common than with tamoxifen.

Fulvestrant is used as second-line treatment in hormone receptor–positive metastatic breast cancer, postmenopausal women with disease progression following antiestrogen therapy. Fulvestrant is given as a monthly intramuscular injection, which might be a deterrent to some patients.

ADMINISTRATION ISSUES

Extravasation

Extravasation, or the leakage of an anticancer outside the blood vessel into the surrounding tissue is a concern for a number of anticancer agents. Antineoplastic agents that cause severe tissue damage when they escape from the vasculature are called vesicants. The tissue damage may be severe, with tissue sloughing and loss of mobility, depending on the area of extravasation. Patients need to be educated to alert clinic staff immediately if there is any pain on administration. If extravasation of a vesicant occurs, the injection should be stopped and any fluid aspirated out of the injection site. The prevention, risk factors, signs and symptoms, causative agents, and treatment will be discussed thoroughly in Chapter 99.

Hypersensitivity Reactions

Hypersensitivity reactions to cancer treatments are problematic because of cross-reactivity between agents and the desire to continue active therapies against the cancer.[32] For documented immediate hypersensitivity reactions to a particular agent, further administration of the agent may be achieved through extensive premedication with H_1 and H_2 antihistamines and corticosteroids and through the use of desensitization protocols which include escalating doses of the offending agent given at doses of one-hundredth, one-tenth, and the balance of the dose (so the total dose administered is equivalent to the normally prescribed dose) administered over a much longer period of time. These treatments must be given in an environment where resuscitation is readily available in case of medical emergency.

Secondary Malignancies

Chemotherapy and radiation therapy treatments may cause cancers later in life; these are referred to as secondary malignancies. The most common types of secondary malignancies are MDS and AML. The antineoplastic agents most commonly associated with secondary malignancies are alkylating agents, etoposide, topoisomerase inhibitors, and anthracyclines. Although the risk for secondary cancers is extremely low, it must outweigh the risk of survival produced by treatment of the primary malignancy. Because secondary malignancies may not occur for several years after treatment, patients with relatively short-term survival expectancy related to their current cancer should consider the more immediate benefits of chemotherapy. Radiation therapy may also cause secondary malignancies decades after treatment. The most common example of radiation therapy–induced secondary malignancy is breast cancer, which rarely occurs after mantle field radiation therapy for Hodgkin disease.

CHEMOTHERAPY SAFETY

One of the first Institute of Medicine (IOM) reports, the health arm of the National Academy of Sciences, starts out with a patient who died from an overdose of chemotherapy; the patient did not have an immediately life-threatening cancer, so her death was hastened by a medication error. Chemotherapy agents may cause harm to patients, healthcare professionals, and the environment if not handled correctly.

KEY CONCEPT Because of the risk of severe toxicities associated with many of the chemotherapy agents, safety precautions must be in place to prevent chemotherapy errors or accidental chemotherapy exposures of healthcare professionals or patients. The American Society of Clinical Oncology (ASCO), Hematology/Oncology Pharmacy Association, Oncology Nursing Society, and the American Society of Health-System Pharmacists have information to assist in the safe handling of chemotherapy agents.[19,33,34] National, state, and local regulations regarding the safe disposal of chemotherapy agents and the equipment used to administer them need to be followed to protect the environment.

KEY CONCEPT Each organization should have chemotherapy safety checks built into the prescribing, preparation, and administration of chemotherapy.[19,33] Dosing based on patient-specific information should be included on every order for chemotherapy, whether it is oral or parenteral. Many chemotherapy regimens are referred to by acronyms (eg, AC, which is doxorubicin and cyclophosphamide); these should not be allowed as the only reference to drugs in the prescribing of chemotherapy. Also, abbreviations for the names of chemotherapy agents should be avoided because one abbreviation may stand for two different drug entities. For drugs such as doxorubicin and liposomal doxorubicin, the names should be written out fully, and in this case, the addition of the brand name may help to prevent a mistake.

The measured height and weight, along with the body surface area (BSA), if applicable, should be readily available, along with the dosage in milligrams per meter squared or kilogram, so that the dosage may be checked. If a chemotherapy regimen is a continuous infusion of 800 mg/m^2/day for 4 days, an added safety feature would be to include the total dosage of 3200 mg in order to prevent any ambiguity. In cases where the clinician wants to decrease the dosage based on a laboratory value or side effect, it is recommended that the clinician include that information with the order so the clinical team caring for the patients understands the correct dosage for that patient. Chemotherapy dosages should be checked for route and dose to determine that the dosages prescribed are correct and do not exceed dosing guidelines. Appropriate laboratory values should be checked

Patient Encounter 2

A 68-year-old woman is receiving nivolumab 1 mg/kg and ipilimumab 3 mg/kg as treatment for intermediate-risk metastatic renal cell carcinoma. While receiving treatment, her aspartate aminotransferase (AST) has risen from 16 to 156 IU/L and alanine aminotransferase (ALT) has risen from 42 to 175 IU/L.

What is the likely diagnosis?

What is the most appropriate treatment?

What measures should be taken by patients while receiving checkpoint inhibitors?

prior to administration so the dose can be adjusted for organ dysfunction or toxicity if needed. See examples in Table 88–8. Additionally, drug interactions should be scrutinized closely and whether the patient has the appropriate indication (eg, presence of EGFR mutation for use of erlotinib).[18] Healthcare professionals administering chemotherapy should check the dosage calculation for the patient's weight or BSA along with the five Rs of administering medication (ie, right patient, right medication, right dose, and right route, at the right time). If there is any question about the safe dosage or safe administration of a chemotherapy agent, the chemotherapy should not be administered until the question is resolved.

In addition, a controversy related to chemotherapy dosing is whether actual or ideal body weight should be used for calculating

Table 88–8

Examples of Dose Modifications in Patients With Hepatic and/or Renal Dysfunction

Agent	Organ Dysfunction	Dose Modification
Bleomycin	*Baseline and during therapy*	
	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 40–50 mL/min	70% of normal dose
	CrCl = 30–40 mL/min	60% of normal dose
	CrCl = 20–30 mL/min	55% of normal dose
	CrCl = 10–20 mL/min	45% of normal dose
	CrCl = 5–10 mL/min	40% of normal dose
	Hepatic dysfunction	No dosage adjustments required
Capecitabine	*Baseline*	
	CrCl > 51 mL/min	Initial: no dosage adjustment
	CrCl = 30–50 mL/min	Initial: 75% of normal dose
	CrCl < 30 mL/min	Contraindicated
	Mild-moderate hepatic impairment	No initial dosage adjustment
	Severe hepatic impairment	Not studied
	During therapy	
	SCr > ULN to 1.5 ULN	No dosage adjustment
	SCr > 1.5–3 × baseline to > 1.5–3 × ULN	No dosage adjustment at first instance
	SCr > 3 × baseline to > 3–6 × ULN	75% dosage adjustment at first instance
	SCr > 6 × ULN	Discontinue therapy
	Total bilirubin > 3–10 × ULN if baseline was normal or > 3–10 × baseline if baseline as abnormal	Interrupt therapy until total bilirubin ≤ 3 × ULN; dosage adjustment is based on dosing guidelines for toxicity
Crizotinib	*Baseline and during therapy*	
	CrCl = 30–89 mL/min	No dosage adjustment
	CrCl < 30 mL/min	Decrease dose to 250 mg once daily
	Baseline	No dosage adjustment
	Mild hepatic impairment	
	Moderate hepatic impairment (total bilirubin > 1.5–≤ 3 × ULN and any AST elevation)	Decrease dose to 200 mg twice daily
	Severe hepatic impairment (total bilirubin > 3 × ULN and any AST elevation)	Decrease dose to 250 mg once daily
	During therapy	
	ALT or AST > 5 × ULN with total bilirubin ≤ 1.5 × ULN	Withhold therapy until recovery until baseline or ≤ 3 × ULN, then resume at reduced dose
	ALT or AST > 3 × ULN with total bilirubin ≥ 1.5 × ULN	Discontinue therapy
Idarubicin	*Baseline and during therapy*	
	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 10–50 mL/min	75% of normal dose
	CrCl < 10 mL/min	50% of normal dose
	Bilirubin 2.6–5 mg/dL	50% of normal dose
	Bilirubin > 5 mg/dL	Do not use
Pembrolizumab	*Baseline*	
	Renal dysfunction	No dosage adjustment
	Mild hepatic impairment	No dosage adjustment
	Moderate-severe hepatic impairment	Has not been studied
	During therapy	
	SCr 1.5–2 × above baseline or increase of ≥ 0.3 mg/dL	Consider holding therapy
	SCr 2–3 × above baseline	Withhold therapy and start prednisone 0.5–1 mg/kg/day
	SCr > 3 × above baseline or > 4 mg/dL	Permanently discontinue and start prednisone 1–2 mg/kg/day
	ALT or AST > 3–5 × ULN with total bilirubin ≥ 1.5–3 × ULN[a]	Withhold therapy and start prednisone 0.5–1 mg/kg/day; resume after taper complete and toxicity resolved
	ALT or AST > 5 × ULN with total bilirubin ≥ 3 × ULN[a]	Permanently discontinue and start prednisone 1–2 mg/kg/day

[a] In patients without hepatocellular or renal cell carcinoma; recommendations are different for these cancers.

AST, aspartate aminotransferase; ALT, alanine aminotransferase; CrCl, creatinine clearance; SCr, serum creatinine; ULN, upper limit of normal.

chemotherapy doses for obese individuals. ASCO guidelines currently recommend the use of actual body weight.[35]

ORAL ANTICANCER AGENTS

KEY CONCEPT Over the past decade, self-administration of oral anticancer agents has increased. Although oral anticancer agents have many potential advantages, including convenience and quality of life for patients, oral administration increases the risk of medication errors and the potential for drug and/or food interactions well as accidental exposure to other individuals. Healthcare professionals have an important role in ensuring safe handling of oral anticancer agents, and should be properly trained and perform competently within guidelines for the storage, handling, and disposal of oral agents. The healthcare professionals are also expected to provide proper training and education on safe handling and proper administration (see Table 88–9) to the patient and caregivers.[33,34,36]

[a] Preferably on an empty stomach; but most importantly consistently with or without food.

CANCER SURVIVORSHIP

KEY CONCEPT As early detection of cancers and effective therapies have improved over the last several years, the number of cancer survivors has increased. A cancer survivor by definition, according to the National Coalition for Cancer Survivorship, starts at the point of diagnosis. It is estimated that two out of every three people with cancer live at least 5 years after diagnosis. In 2005, the IOM released a report, "From Cancer Patient to Cancer Survivor: Lost in Transition," which emphasized a lack of definitive guidance and proposed increased efforts were needed to raise awareness regarding the care of cancer survivors.[37] In addition to facing a risk of a cancer recurrence, secondary malignancy, and an increased risk of developing other health conditions, cancer survivors often face physical, emotional, financial,

Patient Care Process

Collect Information:

- Patient characteristics (eg, age, race, sex, patient preferences)
- Patient history (lifestyle factors—alcohol use, tobacco use, diet, physical activity)
- Patient medical and family history (eg, ECOG performance status, concurrent disease states)
- Clinical presentation signs and symptoms (eg, changes in bowel habits, unusual bleeding, weight loss, recurrent fevers)
- Current medications (prescription, over the counter, and complimentary alternative, medical marijuana)
- Objective data
- BP, heart rate, height, weight, and BSA
  - Labs (eg, serum electrolytes, renal function, liver chemistries, complete blood count, coagulation studies, tumor markers)
  - Other diagnostic test (eg, left ventricular ejection fraction)
  - Physical examination data (eg, hepatomegaly, lymphadenopathy)
  - Cancer staging
  - Tumor genomics (eg, *BRAF, HER-2, PIK3CA, RAS*)

Assess the Information:

- Risk factors for treatment-related toxicities (eg, *UGT1A1*28* genotype, poor nutritional intake, uncontrolled BP or hypertension, baseline peripheral neuropathy)
- Type of and response to prior treatments
- Potential for disease responsiveness to specific agents and risk factors for disease recurrence
- Patient characteristics (eg, social history/situation, insurance coverage, pregnancy) and treatment preferences
- Potential problems with medication adherence to oral treatment regimens
- Goals of treatment
- Need for drug dose reductions or supportive care

Develop a Care Plan*:

- Drug therapy regimen including specific anticancer agent(s), dose (calculated correctly for patient characteristics and disease), route, frequency, and duration
- Supportive care plan (eg, antiemetics, prophylactic antidiarrheals, infusion reaction prophylaxis)
- Monitoring parameters including efficacy (eg, cancer imaging studies-chest, abdominal, and/or pelvic CT scans and radiographs, tumor markers if previously elevated, symptoms of recurrence), safety (medication-specific adverse effects, including major dose-limiting toxicities), and timeframe
- Patient education (eg, goals of treatment; expected and potential serious toxicities; drug therapy; monitoring and management plan; safe administration, storage, and disposal)

Implement the Care Plan*:

- Provide patient education regarding all elements of treatment plan
- Survivorship care plan (eg, primary prevention of other diseases, such as infections, and other cancers, support systems for maintaining healthy lifestyle choices and BMI)

Follow-up: Monitor and Evaluate:

- Determine disease response to treatment and occurrence of disease progression or recurrence (cancer imaging studies, tumor markers previously elevated)
- Presence of adverse effects
- Patient adherence to treatment plan using multiple sources of information (eg, patient self-report, medication administration records or refill data)
- Patient's satisfaction with treatment, including understanding of adherence

*Collaborate with patient, caregivers, and other healthcare professionals

and social challenges as a result of the cancer diagnosis and treatment. The American Cancer Society (ACS), Centers for Disease Control, ASCO, and the NCCN all have guidelines that describe strategies to meet the needs of these individuals who experience the long-term effects of cancer and its treatment.[38-40]

OUTCOME EVALUATION

Once a pathologic diagnosis of cancer is made, the patient may be evaluated by a radiation oncologist, a surgical oncologist, and a medical oncologist. Options for treatment are presented that may include surgery, radiation, pharmacologic therapy, or some combination of these modalities. The goals of treatment vary by the cancer and the stage of disease. For example, the patient who has metastatic kidney cancer could be presented with several options. They may have a possible cure with high-dose aldesleukin or receive palliative therapy with pazopanib or sunitinib, or the patient may decline any therapy because of fears of significant toxicity that would decrease quality of life. In this case, if the patient's performance status is poor, such as an ECOG performance status 3, then the patient would not be a candidate for aldesleukin therapy because of significant toxicity or even death from treatment. The patient with the poor performance status will receive palliative therapy to control symptoms of the disease to improve the quality of life at the end of life. For the patient with a poor performance status and extensive metastatic disease, no treatment of the cancer may be appropriate, and the patient may be enrolled in a hospice program or provided comfort care.

Abbreviations Introduced in This Chapter

2-FLAA	2-Fluoro-Ara-AMP
5-FU	5-Fluorouracil
6-MP	6-Mercaptopurine
ACS	American Cancer Society
ADC	Antibody–drug conjugate
ADCC	Antibody-dependent cellular cytotoxicity

AI	Aromatase inhibitor
ALK	Anaplastic lymphoma kinase gene
ALL	Acute lymphocytic leukemia
ALT	Alanine aminotransferase
AML	Acute myeloid leukemia
APL	Acute promyelocytic leukemia
AR	Androgen receptor
ASCO	American Society of Clinical Oncology
ATRA	All-*trans*-retinoic acid
AST	Aspartate aminotransferase
AUC	Area under the curve
BSA	Body surface area
Bcl-2	B-cell lymphoma 2
BCNU	Carmustine
BP	Blood pressure
BTK	Bruton's tyrosine kinase
c-MET	Mesenchymal epithelial transition growth factor
CAR	Chimeric antigen receptor
CBC	Complete blood count
CCNU	Lomustine
CD	Cluster of differentiation
CDK	Cyclin-dependent kinase
CLL	Chronic lymphocytic leukemia
CML	Chronic myeloid leukemia
CNS	Central nervous system
CrCl	Creatinine clearance
CRS	Cytokine-release syndrome
CT	Computed tomography
CTLA-4	Cytotoxic T-lymphocytic-associated antigen 4
CYP	Cytochrome P450
CYP17	17α-hydroxylase/C17,20-lyase
DNA	Deoxyribonucleic acid
DPD	Dihydropyrimidine dehydrogenase
DVT	Deep vein thrombosis
ECOG	Eastern Cooperative Oncology Group
EGFR	Epidermal growth factor receptor
ER	Estrogen receptor
FDA	Food and Drug Administration
FdUMP	Fluorodeoxyuridine monophosphate
FGFR	Fibroblast growth factor receptor
G-CSF	Granulocyte–colony stimulating factor
GI	Gastrointestinal
GIST	Gastrointestinal stromal tumor
GnRH	Gonadotropin-releasing hormone
H	Histamine
HDAC	Histone deacetylase
HER-2	Human epidermal receptor-2
HFS	Hand–foot syndrome
HFSR	Hand–foot–skin reaction
HPV	Human papillomavirus
HR	Heart rate
HSCT	Hematopoietic stem cell transplantation
IDH	Isocitrate dehydrogenase
IOM	Institute of Medicine
INR	International normalization ratio
IV	Intravenous
LDH	Lactate dehydrogenase
LHRH	Luteinizing hormone–releasing hormone
MDS	Myelodysplastic syndrome
MEK	Mitogen-activated extracellular kinases
MM	Multiple myeloma
MMAE	Monomethyl auristatin E
MMAF	Monomethyl auristatin phenylalanine
MRI	Magnetic resonance imaging
mTOR	Mammalian target of rapamycin
NCI	National Cancer Institute
NCCN	National Comprehensive Cancer Network
NSCLC	Non–small cell lung cancer
NTRK	Neurotrophic tyrosine receptor kinase
OTC	Over-the-counter
PARP	Poly ADP ribose polymerase
PCR	Polymerase chain reaction
PD	Programmed cell death
PD-L	Programmed cell death ligand
PET	Positron emission tomography
PI3-K	Phosphoinositide 3-kinase
PSA	Prostate-specific antigen
RAS	Reticular activing system
RECIST	Response evaluation criteria in solid tumors
REMS	Risk Evaluation and Mitigation Strategies
RNA	Ribonucleic acid
SC	Subcutaneous
SERDs	Selective estrogen-receptor downregulators
SERMs	Selective estrogen receptor modulator
SMO	Smoothened
SPF	Sun protection factor
TKI	Tyrosine kinase inhibitor
TNM	Tumor, nodes, metastases
TPMT	Thiopurine *S*-methyltransferase
TS	Thymidylate synthase
UGT1A1*28	Uridine diphosphate–glucuronosyltransferase 1A1 enzyme
VEGF	Vascular endothelial growth factor
VEGFR	Vascular endothelial growth factor receptor
XOP1	Exportin 1

89 Breast Cancer

Gerald M. Higa

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Detail epidemiological and clinical disparities of the disease.
2. Analyze risk factors associated with, and strategies that can modify the risk of, developing breast cancer.
3. Summarize the surrogate definitions of the intrinsic breast cancer subtypes.
4. Recognize signs and symptoms related to early and late stages of the disease.
5. Distinguish between good and poor prognostic factors.
6. Determine treatment goals for early-stage, locally advanced, and metastatic breast cancers.
7. State the rationale for inclusion of adjuvant and neoadjuvant therapies.
8. Describe the relevance of hormone, HER2, and PD-1 receptors.
9. Discuss the benefits and risks associated with various therapies.

INTRODUCTION

The growing prevalence of breast cancer in the United States is related to early detection, improved therapies resulting in longer survival and and the relatively high incidence rate. Breast cancer prevalence is increasing in the United States related to early detection, improved therapies resulting in longer survival and the increasing incidence rate. The increased incidence appears to be driven almost exclusively by new breast cancer diagnoses in non-White women.

EPIDEMIOLOGY AND ETIOLOGY

Breast cancer is the most common type of cancer, and second only to lung cancer as a cause of cancer death, in American women. In 2021, female breast cancer will account for 99% of the projected 284,000 new cases, the median age at diagnosis will be 62 years, and and approximately 43,600 deaths will be attributable to the disease.[1] KEY CONCEPT Even though breast cancer occurs more frequently in non-Hispanic White (nHw) women than any other ethnic group, the mortality rate is highest among African Americans.

Tumor size of most breast cancers at diagnosis is usually small (less than 2 cm), and localized disease predominates in all racial and ethnic groups. However, non-Hispanic Black women have the highest rates of triple-negative breast cancers (TNBCs) and proportionally more cases of advanced disease compared with nHw women. Reduced access to proper medical care, including breast cancer screening programs, as well as certain biological factors, may contribute to late diagnoses.

KEY CONCEPT The etiology of breast cancer remains largely unknown though a number of factors have been associated with the risk of developing the disease. Evidence also strongly suggests that breast cancer biology involves complex interactions between sex hormones, genetic factors, environment, and lifestyle. The intrinsic and extrinsic components associated with the disease are discussed further.

Patient Encounter, Part 1

The topic of a recent meeting of the Sierra Club, a women-only group, was breast cancer. A number of women expressed that they knew some people who have or had the disease, many of who were labeled "survivors." Nearly all of the women in the club expressed that being diagnosed with breast cancer was one of their greatest fears.

Discuss relevant breast cancer risk factors.

Intrinsic Components

Aside from gender, the variable most strongly associated with breast cancer risk is age. One of the most frequently quoted breast cancer statistics is the probability that one in eight females will develop the disease sometime in their lifetime. However, a more instructive way of explaining the age-related risk is shown in Table 89–1**.** Although the probability of developing breast cancer increases with age, in more than half, the risk occurs after 60 years of age.

Both personal and family history can influence the risk of developing breast cancer. For example, a woman who has a history of breast cancer has a fivefold increase in the risk of developing contralateral breast cancer. Prior histories of cancers involving the uterus and ovary also appear to be associated with an increased risk of developing breast cancer. Even though family history is often linked to disease risk, the percentage of familial breast cancer is quite low (ie, ~10%). KEY CONCEPT The following key elements describe family history-associated breast cancer risk factors:

- A first-degree relative (ie, mother or sister) with breast cancer is associated with a threefold increase in risk.
- Multiple first-degree relatives with breast cancer have not been consistently shown to be associated with risk greater than one first-degree relative.

Table 89–1

Risk of Developing Breast Cancer: SEER Areas, Women, All Races, 2012–2014

Age Interval (Years)	10-Year Probability
30–40	0.5% or 1 in 220
40–50	1.5% or 1 in 68
50–60	2.3% or 1 in 43
60–70	3.4% or 1 in 29
70–80	3.9% or 1 in 25
From birth to death	12.4% or 1 in 8

SEER, Surveillance, Epidemiology and End Results.

Probability derived by Devcan 6.7.0, June 2017 (http://surveillance.cancer.gov/devcan).

- A second-degree relative with breast cancer is associated with a 1.5-fold increase in risk.
- Family members on the paternal side contribute to risk similar to the maternal side.

KEY CONCEPT The endocrine factor most closely linked to breast cancer is estrogen. The risk is partially related to the duration of exposure to the hormone. Hence, early menarche and late menopause, nulliparity, and certain hormone replacement therapy (HRT) appear to contribute to breast cancer risk. Use of HRT in postmenopausal women is infrequent and generally contraindicated for women with a history of breast cancer based on the Women's Health Initiative (WHI) hormone therapy trial, which demonstrated an increased risk of breast cancer in those receiving HRT.[2]

KEY CONCEPT In the early 1990s, the *BRCA1* gene was found to be mutated in a large percentage of hereditary breast and ovarian cancer patients. A second breast cancer gene, called *BRCA2*, has also been identified. Functional aberrations of *BRCA1* and *BRCA2* result in the loss of key inhibitory activities of both proteins. Compelling evidence of their critical importance is the observation that women who carry germline mutations of *BRCA1* or *BRCA2* have a lifetime risk of breast cancer between 65% and 90%; the 10-year risk of contralateral breast cancer is approximately 25% to 30%. Women with strong family histories of breast cancer are candidates for *BRCA1* and *BRCA2* mutation analysis.

Extrinsic Components

Experimental and epidemiologic evidence suggest a link between breast cancer and being overweight after menopause, especially with body fat distributed around the abdominal region. This risk factor may be related, in part, to peripheral conversion of androgens to estrogens in adipose tissue. In addition, obesity is associated with reduced overall survival in women with hormone receptor–positive breast cancer.[3] Data also indicate a modest relationship between alcohol consumption and breast cancer. And although epidemiological data have been inconsistent, biological evidence suggests smoking is associated with a small, though significant, increase in the risk of developing breast cancer, especially with early initiation (ie, less than 17 years of age) of tobacco use.

Radiation is also associated with an increased risk of breast cancer. Although the risk appears to be dosage-related, the minimal level of exposure is not well defined. Even therapeutic doses of radiation administered in the management of patients with postpartum mastitis, tuberculosis, and certain hematologic malignancies appear to increase breast cancer risk. Notably, this risk appears to be confined to exposure before 40 years of age, which suggests that a "window of initiation" for breast cancer occurs relatively early. On the other hand, it is currently accepted that exposure to radiation doses utilized in diagnostic X-rays, including screening mammography, are not of clinical concern.

KEY CONCEPT The majority of women diagnosed with breast cancer do not have any of the identified risk factors (other than age). Risk of breast cancer can be assessed using the National Cancer Institute online version of the Breast Cancer Risk Assessment Tool that is considered to be the most authoritative and accurate (www.cancer.gov/bcrisk-tool). This tool was designed for health professionals to project individualized 5-year and lifetime risks for invasive breast cancer.

Prevention of Breast Cancer

Even though breast cancer is not the most lethal malignancy, disease-related morbidity and mortality is still a major concern. Current efforts at breast cancer prevention are directed toward the identification and removal of risk factors. Unfortunately, a number of risk factors such as age and family or personal history of the disease or other gynecologic malignancies cannot be modified.

The idea that prevention can be achieved pharmacologically was based on clinical trials of tamoxifen, a selective estrogen receptor modulator (SERM), as adjuvant therapy for women with early, hormone receptor–positive breast cancer. These trials demonstrated a reduction of contralateral breast cancer events as well as a survival advantage of patients who received the drug for 2 to 5 years following mastectomy. Several clinical trials conducted with SERMs provided proof of principle that breast cancer risk reduction in premenopausal and postmenopausal women could be achieved through chemoprevention.[4,5]

In addition, a class of drugs known as the aromatase inhibitors (AIs) has been shown to be more effective than tamoxifen as adjuvant breast cancer therapy in postmenopausal women. This finding suggested that the AIs could also reduce the risk of developing breast cancer in postmenopausal women at high risk for the disease. Results of the International Breast Cancer Intervention Study (IBIS)-II demonstrated a 53% reduction in new breast cancer diagnoses with anastrozole compared to placebo.[6] Similar findings have been reported with the steroidal AI, exemestane, in high-risk postmenopausal women.

These positive findings are accompanied by a number of caveats. First, chemoprevention effectively reduces the incidence without a significant benefit in OS. Second, risk reduction appears to apply to hormone-dependent breast cancer only. Third, results of these trials confirmed the increased incidence of thromboembolic and gynecological adverse events associated with tamoxifen but not raloxifene. Fourth, AIs are not currently approved for preventing breast cancer, but if used off-label, they are only effective for postmenopausal women. Interestingly, adverse effects on the musculoskeletal system were not (or infrequently) observed in the prevention trials compared to the adjuvant trials of these agents. Fifth, the role of tamoxifen in *BRCA* mutation carriers is still not clear. In women with familial breast cancer, bilateral mastectomy remains the best, though not absolute, risk-reducing option. Sixth, in contrast to estrogen alone, the WHI study mentioned previously indicated that HRT with estrogen and progestin increased breast cancer risk and mortality.

It should be noted that even though the side-effect profiles of the SERMS and AIs negatively impact patient acceptance, pharmacological prevention could spare some patients from surgery, radiation, and even chemotherapy-related morbidity.

Table 89–2

Intrinsic Subtypes of Breast Cancer

Subtype	Tumor Features	Treatment Approach	Added Comment
Luminal A	All of the following: ER and PR positive, HER2 negative, and low Ki67 (proliferation marker)	Endocrine only (usually)	May add chemotherapy if four or more positive nodes, grade 3 disease, Oncotype Dx recurrence score > 25, or age < 35 years
Luminal B (HER2 negative)	ER positive, HER2 negative, and either high Ki67 or PR negative	Endocrine and chemotherapy (for most cases)	Add chemotherapy for most patients
Luminal B (HER2 positive)	ER positive, HER2 positive	Endocrine, HER2-targeted therapy and chemotherapy	
HER2 amplified or overexpressed (nonluminal)	HER2 positive	HER2-targeted therapy and chemotherapy	Opinion differs regarding use of anti-HER2 therapy in tumors < 5 mm
Basal (triple negative)	ER, PR, and HER2 negative	Chemotheraphy. First-line atezolizumab plus nab-paclitaxel approved for women with locally advanced surgically-unresectable or metastatic disease if tumors express PD-L1.

PATHOPHYSIOLOGY

Histologic evaluation of breast lesions serves to establish a pathologic diagnosis and confirm the presence of other factors believed to influence prognosis.

Invasive Breast Cancer

Breast cancers typically arise in the ducts or lobules of the mammary gland. When tumor cells infiltrate surrounding breast tissue, a diagnosis of invasive breast cancer is made. Even though the vast majority of tumors are adenocarcinomas, this does not imply that breast cancer is one disease. Furthermore, breast cancers can be grouped in one of four intrinsic subtypes with luminal B having two distinct surrogate features. When defined by clinical and pathological features, this classification system can be used for prognostication as well as a guide to treatment (Table 89–2*)*.

Noninvasive Carcinoma

Notably, the annual breast cancer incidence does not include thousands of cases of carcinomas *in situ* (ie, noninfiltrating tumors confined to the ducts and lobules). Ductal carcinoma *in situ* (DCIS) accounts for approximately 85% of all *in situ* breast cancers; while lobular neoplasia may not be a true cancer, rather a high-risk premalignant lesion that does not always require active treatment. The overwhelming majority of cases can be cured by surgery followed by whole breast radiation therapy after breast-conserving surgery (BCS). Although there is no proven role for the application of cytotoxic chemotherapy, patients with hormone receptor–positive tumors may benefit from the addition of tamoxifen.

Patient Encounter, Part 2

Discussion among the women progresses to early detection. Except for age within this group of mostly elderly women, most indicate they do not appear to have additional risk factors. The most commonly used screening tool is mammography. Even though performed, the role and utility of clinical breast examination have been questioned. Nonetheless, the ultimate goal of screening is to reduce breast cancer morbidity and mortality.

Discuss screening of "average-risk" women focusing on when to initiate discussion, when to start screening, mammographic interval, relative benefits of screening (in terms of decreased mortality) based on age, and potential harms associated with mammography.

CLINICAL PRESENTATION AND DIAGNOSIS

Early Detection

The rationale for early detection of breast cancer is based on the clear relationship between early-stage disease at diagnosis and greater probability of long-term survival. Screening guidelines for early detection of breast cancer have been published by the American Cancer Society (ACS), the United States Preventive Services Task Force (USPSTF), and the National Comprehensive Cancer Network (NCCN) (Table 89–3). All include recommendations that women aged 50 to 74 of average risk have annual or biennial screening. Controversy regarding the use of screening mammography is largely confined to women younger than 50 years. After many years of debate, NCCN and ACS recommend initiation of screening at age 40, while USPSTF recommends that in this age group, the decision should be an individual one.[7]

Diagnosis

Unless following up on abnormalities found during screening, the initial workup for women presenting with signs or symptoms (see the "Clinical Presentation and Diagnosis" section) suggestive of breast cancer should include a careful history, physical examination of the breast, three-dimensional mammography, and possibly other imaging techniques such as magnetic resonance imaging. Most (80%–85%) breast cancers are visualized on a mammogram as a mass, a cluster of calcifications, or a combination of both. A breast biopsy is indicated for a mammographic abnormality that suggests malignancy or a palpable mass on physical examination.

Table 89–3

Guidelines for Early Detection of Breast Cancer in Average-Risk Individuals

	American Cancer Society	US Preventive Services Task Force	National Comprehensive Cancer Network
BSE	NR (no clear benefit)	NR	25–39 years, breast awareness
CBE	NR (no clear benefit)	Not specifically addressed	25–39 years, every 1–3 years then annually > 39 years
Mammography	40–44 years, option to start 45–54 years, annual > 54 years, annual or biennial	Age 50–74 years: Every 2 years (with or without CBE)	Age 40, begin annual scans

BSE, breast self-examination; CBE, clinical breast examination; NR, not recommended.

Clinical Staging

The preferred method of staging includes the combination of anatomic (ie, tumor size [T], lymph node status [N], and metastasis [M]) and prognostic variables (ie, tumor grade and biomarkers such as human epidermal–related growth factor receptor [HER] 2 and estrogen and progesterone receptors [ER and PR]). In general, TNM (Tumor, node, metastasis [staging system]) stage (0–4) is defined as follows: carcinoma in situ (0), tumors less than 2 cm in diameter (1 or 2), 5 cm or greater (3), and metastatic (4). **KEY CONCEPT** Though dependent on multiple tumor and clinical characteristics, survival has improved across all stages of the disease. The overall 5-year survival rate is approximately 90%; nearly all of those with localized disease are alive at 5 years.

Clinical Presentation and Diagnosis of Breast Cancer

Common early signs and symptoms include the following:

Painless lump (90% of cases) that is:

- Solitary
- Unilateral
- Solid
- Irregular
- Nontender

Stabbing or aching pain (10% of cases) as the first symptom

Uncommon early signs and symptoms include the following:

Nipple discharge (3% of women and 20% of men), retraction, or dimpling

- Eczema appearance of the nipple (Paget carcinoma)
- Prominent skin edema, redness, warmth, and induration of the underlying tissue (inflammatory carcinoma)

Sites of metastases frequently include bone, liver, lung and brain. The following signs and symptoms of metastases are present in about 10% of patients when they first seek treatment:

- Bone pain
- Pathologic fracture
- Difficulty breathing
- Jaundice
- Abdominal pain
- Headache
- Mental status changes

Prognostic Factors

Good prognostic factors include the following:

- Luminal A subtype (ER and PR highly positive, Ki67 low)
- Absence of tumor cells in regional nodes (node-negative)
- Tumors smaller than 2 cm
- Early stage (1 or 2)
- Well-differentiated tumor
- Normal tumor grade

Poor prognostic factors include the following:

- Age younger than 35 years
- High nuclear grade (correlates with tumor growth)
- Triple-negative disease (ie, the absence of ER, PR, and HER2)
- Overexpression of HER2 alone

Patient Encounter, Part 3

After the above meeting, one of the younger women (age 50 and still having menstrual periods) makes an appointment with her family physician because of some unexplained pain in her right breast. Even though her doctor is unable to palpate a tumor or axillary node, a mammogram is ordered. Other than gender, the patient is not aware of any additional risk factors. Results of the mammogram showed a suspicious calcified lesion, approximately 1.6 cm in diameter, in the right upper outer quadrant. The radiologist recommended obtaining a core biopsy of the lesion. Pathologic review showed marked atypia with a focal nest of neoplastic cells. Tumor staining was notable for the absence of hormone receptors but overexpression of HER2. Additional tests indicated a poorly differentiated, high-grade tumor and high Ki67 proliferation index.

List important facets regarding screening in general. Discuss whether the woman had a screening mammogram. In addition, characterize the intrinsic subtype as well as predictive and prognostic features.

EARLY BREAST CANCER TREATMENT

Desired Outcome

KEY CONCEPT Most patients presenting with invasive breast cancer have small tumors with negative lymph nodes (stage 1 or 2). The goal of therapy for early breast cancer is cure. While surgery alone may be able to cure approximately one-third to one-half of all patients with early-stage breast cancer, certain tumor features warrant addition of systemic therapy.

Surgical procedures have changed significantly over the last 50 years. **KEY CONCEPT** Less aggressive surgical options for invasive early breast cancer include total mastectomy or BCS such as lumpectomy. The reason for favoring the latter is based on findings that BCS achieves similar survival outcomes as more extensive surgical procedures and is cosmetically superior. Additionally, breast conservation aids in preserving the emotional and psychological well-being of the patient.[8] Only two contraindications to BSC are considered absolute (or nearly absolute), including persistence of tumor on surgical margins and inability to perform postsurgery radiation, if indicated.

KEY CONCEPT Equally important is the issue related to axillary lymph node dissection (ALND). Because of the morbidity associated with the procedure, a clinical trial was conducted to determine the impact of sentinel lymph node (SLN) biopsy on disease outcomes. Results of this study indicated that ALND can be omitted with less than three positive sentinel nodes when postmastectomy radiation is planned.[9]

Except for the elderly and patients with substantial comorbid medical conditions, radiation therapy should be considered an integral adjunct to BCS especially in those with more than three positive nodes or those with positive sentinel nodes without ALND. However, a recent meta-analysis of trials indicated similar survival outcomes among subjects with stage 1, low-risk breast cancer regardless if they received radiation or not the following lumpectomy. What used to entail 4 to 6 weeks of external-beam radiation, newer clinical evidence supports the efficacy of a 3-week course of whole breast irradiation.[10] Complications associated with radiation therapy are usually minor and include erythema of the breast tissue and shrinkage of total breast mass beyond that predicted on the basis of surgical resection alone.

Systemic Adjuvant Therapy

Breast cancer cells can spread by contiguity, lymphatic channels, and blood to distant sites. Tumor cells often metastasize early in cancer growth. Because these deposits cannot always be detected with current diagnostic techniques, they are referred to as occult metastases. Hence, administration of adjuvant therapy (at a time when the tumor burden is low) should theoretically increase the likelihood of cure and minimize the emergence of drug-resistant tumor cell clones. **KEY CONCEPT** Most published results confirm that chemotherapy (in selected patients), hormonal therapy (in patients with hormone receptor–positive disease), anti-HER2 therapy (in tumors with amplification or overexpression of HER2), or appropriate combinations of these therapies improved disease-free survival (DFS) and/or OS in patients with early-stage breast cancer (see Table 89–2).

Among the most influential groups that provide treatment recommendations is the St. Gallen International Expert Consensus panel.[11]

▶ *Adjuvant Chemotherapy*

Cytotoxic drugs that are used most frequently as adjuvant therapy of breast cancer include the taxanes, anthracyclines, and cyclophosphamide. The most common chemotherapy regimens used in the adjuvant setting are listed in Table 89–4. Dose-limiting and other significant toxicities have been previously described in Chapter 88 and are discussed succinctly in Table 89–5.

Chemotherapy is usually initiated within 2 to 6 weeks from the surgical procedure; the efficacy of systemic therapy decreases if

Table 89–4

Common Chemotherapy Regimens for Breast Cancer

Adjuvant Chemotherapy Regimens

AC
Doxorubicin 60 mg/m^2 IV, day 1
Cyclophosphamide 600 mg/m^2 IV, day 1
Repeat cycles every 21 days for four cycles[a]

AC → Paclitaxel (CALGB 9344)
Doxorubicin 60 mg/m^2 IV, day 1
Cyclophosphamide 600 mg/m^2 IV, day 1
Repeat cycles every 21 days for four cycles
Paclitaxel 175 mg/m^2 on day 1

CMF
Cyclophosphamide 100 mg/m^2/day orally, days 1–14
Methotrexate 40 mg/m^2 IV, days 1 and 8
Fluorouracil 600 mg/m^2 IV, days 1 and 8
Repeat cycles every 28 days for six cycles[b,c]
or
Cyclophosphamide 600 mg/m^2 IV, day 1
Methotrexate 40 mg/m^2 IV, day 1
Fluorouracil 600 mg/m^2 IV, days 1 and 8
Repeat cycles every 28 days for six cycles[d]

Dose-Dense AC → Paclitaxel
Doxorubicin 60 mg/m^2 IV bolus, day 1
Cyclophosphamide 600 mg/m^2 IV, day 1
Repeat cycles every 14 days for four cycles (must be given with growth factor support)
Followed by:
Paclitaxel 175 mg/m^2 IV over 3 hours
Repeat cycles every 14 days for four cycles (must be given with growth factor support)[e]
Followed by:
Paclitaxel 175 mg/m^2 IV over 3 hours
Repeat cycles every 21 days for four cycles[f]

TC
Docetaxel 75 mg/m^2 IV over 60 minutes, day 1
Cyclophosphamide 600 mg/m^2 over 30–60 minutes, day 1
Repeat cycles every 21 days for four cycles

(Continued)

Table 89–4

Common Chemotherapy Regimens for Breast Cancer (*Continued*)

Metastatic Single-Agent Chemotherapy

Paclitaxel
Paclitaxel 175 mg/m^2 IV over 3 hours
Repeat cycles every 21 days
or
Paclitaxel 80 mg/m^2/week IV over 1 hour
Repeat dose every 7 days[g]

Docetaxel
Docetaxel 60–100 mg/m^2 IV over 1 hour
Repeat cycles every 21 days[i]
or
Docetaxel 30–35 mg/m^2/week IV over 30 minutes
Repeat dose every 7 days[j]

Capecitabine
Capecitabine 2000–2500 mg/m^2/day orally, divided twice daily for 14 days
Repeat cycles every 21 days[k,l]

Vinorelbine
Vinorelbine 30 mg/m^2 IV, days 1 and 8
Repeat cycles every 21 days
or
Vinorelbine 25–30 mg/m^2/week IV
Repeat cycles every 7 days (adjust dose based on absolute neutrophil count; see product information)[h]

Gemcitabine
Gemcitabine 600–1000 mg/m^2/week IV, days 1, 8, and 15
Repeat cycles every 28 days (may need to hold day 15 dose based on blood counts)[k]

Liposomal Doxorubicin
Liposomal doxorubicin 30–50 mg/m^2 IV over 90 minutes
Repeat cycles every 21–28 days[m]

Table 89–5

Toxicities of Common Chemotherapies Used for Breast Cancer

Class	Drug	Dose-Limiting Toxicities	Other Toxicities
Anthracyclines	Doxorubicin, epirubicin	Myelosuppression, cardiomyopathy	Alopecia, nausea, vomiting, stomatitis, ulceration, and necrosis with extravasation, red-colored urine, radiation recall effect
	Liposomal doxorubicin	Myelosuppression, palmar-plantar erythrodysesthesia (hand–foot syndrome)	Alopecia, infusion reactions, stomatitis, fatigue, nausea, vomiting
Taxanes	Paclitaxel	Neutropenia, peripheral neuropathy, hypersensitivity reactions	Alopecia, fluid retention, myalgia, skin reactions, ulceration, and necrosis with extravasation, bradycardia, stomatitis
	Docetaxel	Myelosuppression, severe fluid retention	Alopecia, fatigue, stomatitis, nausea, vomiting, diarrhea, peripheral neuropathy, nail disorder, skin reactions, hypersensitivity reactions
Antimetabolites	Capecitabine	Diarrhea, palmar-plantar erythrodysesthesia (hand–foot syndrome)	Myelosuppression, stomatitis, nausea, vomiting
	Gemcitabine	Myelosuppression (especially thrombocytopenia)	Flu-like syndrome (fever, chills, myalgias, and arthralgias), nausea
	Fluorouracil	Myelosuppression	Stomatitis, diarrhea, alopecia
	Methotrexate	Myelosuppression, stomatitis	Diarrhea, nausea, vomiting, renal toxicity
Vinca alkaloids	Vinorelbine	Neutropenia	Fatigue, nausea, vomiting, ulceration, and necrosis with extravasation
Alkylating agents	Cyclophosphamide	Myelosuppression, hemorrhagic cystitis	Alopecia, stomatitis, amenorrhea, aspermia

delayed more than 12 weeks following surgery. Currently, four to eight cycles of chemotherapy are administered for 12 to 24 weeks. Dose reduction for standard chemotherapy regimens should be avoided in the absence of severe acute toxicity because of the negative impact on DFS and OS. Even though most patients are able to maintain a reasonable level of functional, emotional, and social well-being during treatment, there are some compelling data indicating that some toxicities can have chronic debilitating effects on the quality of life.[12] Various forms of supportive therapy, including antiemetics and hematopoietic growth factors for patients receiving systemic adjuvant chemotherapy, are discussed in Chapter 99.

As mentioned previously, the usefulness of the intrinsic subtype classification also extends to treatment strategies. Since the magnitude of the 10-year survival benefit with cytotoxic agents appears to be only 5% and 10% for patients with negative and positive nodes, respectively, there has been intensive research to identify patients with low-risk disease that could avoid treatment with chemotherapy. One validated multigene assay known as Oncotype DX is used in patients with luminal A disease and limited nodal involvement, to determine who can be treated with endocrine therapy alone.[13]

KEY CONCEPT It is generally agreed that patients with high-risk luminal B, HER2 overexpression, and basal-like subtypes should receive chemotherapy (both anthracycline and taxane) with hormonal and/or HER2-targeted therapy if indicated.[14]

▶ *Adjuvant Anti-HER2 Therapy*

HER2 amplification or overexpression is found in approximately 15% to 20% of all breast cancers. Because of its aggressive features, treatment targeting the receptor (plus chemotherapy) is indicated in this subset of patients, especially for tumors greater than or equal to 0.5 cm in size. Most experts agree that HER2-positive tumors appear to derive greater benefit from anthracycline or taxane-based chemotherapy regimens. When used with these two classes of cytotoxic agents, trastuzumab is given either following completion of the anthracycline or concurrently with the taxane. However, the combination of trastuzumab and pertuzumab should be considered in patients with positive nodes or stage 2 or 3 tumors. One additional issue of relevance relates to the risk of trastuzumab-associated cardiac toxicity. Noninferiority of 6 months compared to standard 12 months trastuzumab has been demonstrated prospectively in one study; however, the shorter course is not standard of care.[15]

▶ *Adjuvant Endocrine Therapy*

Hormone receptors are used clinically to gauge prognosis, predict response to endocrine therapy, and discriminate luminal breast cancer subtypes. Approximately 50% to 70% of patients with breast cancer have hormone receptor–positive tumors. However, receptor positivity refers to tumors expressing both ER and PR, as well as either ER or PR alone. Furthermore, "ER-positive" tumors traditionally refer to ERα only. Although it is beyond the scope of this discussion, it is noteworthy to mention the existence, and accumulating data regarding the roles of ERβ and the ERα/ERβ heterodimer in breast cancer.[16,17] Tumors with high expression of both ER and PR (ie, luminal A subtype) are associated with favorable prognoses, superior responses to endocrine therapy, and longer disease-free intervals following initial treatment. Hormone receptor–positive tumors are more common in postmenopausal patients.

KEY CONCEPT Hormonal therapies that have been studied in the treatment of early breast cancer include tamoxifen, ovarian suppression (surgical and pharmacologic), and the AIs.

Duration of adjuvant endocrine therapy has historically been for 5 years. However, ER-positive tumors retain a substantial risk of recurrence beyond the initial 5-year period. Studies demonstrate a longer duration of endocrine therapy can reduce recurrence.[18,19] However, the greatest benefit appeared among women who initially received tamoxifen then switched to an AI. The strategies of extended monotherapy tamoxifen or AI were found to be proportionately less beneficial. Extended therapy can be considered after careful assessment of potential clinical benefits and risks related to tumor features and patient characteristics, including comorbidities, bone mineral density, and prior tolerance with AI therapy.

Another issue that may be related to overall prognosis is the observation that premenopausal breast cancer is biologically more aggressive than breast cancers diagnosed after menopause. Reduction in recurrence and an emerging survival benefit are being seen with long-term follow-up of a clinical trial of ovarian function suppression in combination with either tamoxifen or an AI in younger women with ER-positive breast cancer, particularly women with higher grades or higher stage cancers.[20]

Endocrine therapy is initiated shortly after surgery or as soon as pathology results are known. However, when chemotherapy is also indicated, endocrine therapy is given after all cytotoxic agents have been completed. This approach has been adopted based on possible harm and lack of convincing evidence of apparent benefit when given concurrently. In addition to tamoxifen, three AIs, anastrozole, letrozole, and exemestane are available (Table 89–6).

LOCALLY ADVANCED BREAST CANCER TREATMENT

Desired Outcome

Locally advanced breast cancer (LABC) is defined by size, 2 cm or greater, and nodal involvement, high likelihood, in the absence of measurable metastasis. Clinically, LABC includes stage 2 or 3, HER2-positive, triple-negative, and inflammatory breast cancers. The latter is a unique clinical entity that has, at times, been misdiagnosed as cellulitis. Notably, patients with stage 2B, 3A, and 3B tumors have much poorer prognosis with 5-year rates of 70%, 52%, and 48%, respectively.

Initial management for LABC is the use of cytotoxic or endocrine therapy as well as HER2-directed therapies (if indicated) prior to surgery. This approach, referred to as systemic neoadjuvant therapy (SNT), can render initially inoperable tumors resectable, even with the possibility of BCS. In addition, the application of SNT enables some patients to avoid some of the morbidities associated with axillary dissection. Furthermore, tailoring the initial approach to triple-negative and HER2-positive breast cancers can improve disease outcomes.

Pharmacologic Therapy

One of the treatment objectives for patients with high-risk LABC is to obtain tumor resectability. The guidelines for selection and duration of SNT are similar to the adjuvant setting. Available data support the use of anthracycline- and/or taxane-containing regimens as well as any approach to improve dose density or dose intensity. In patients with HER2-overexpressing tumors, the combination of a taxane, carboplatin, and trastuzumab with or

Table 89–6

Endocrine Therapies for Breast Cancer

Class	Drug	Dose	Side Effects
Aromatase inhibitors			
Nonsteroidal	Anastrozole	1 mg/day PO	Hot flashes, arthralgias, myalgias, headaches, diarrhea, mild nausea
	Letrozole	2.5 mg/day PO	
Steroidal	Exemestane	25 mg/day PO	
Antiestrogens			
SERMs	Tamoxifen	20 mg/day PO	Hot flashes, vaginal discharge, mild nausea, thromboembolism, endometrial cancer
	Toremifene	60 mg/day PO	
SERDs	Fulvestrant	250 mg IM every 28 days	Hot flashes, injection-site reactions, possibly thromboembolism
LHRH analogues	Goserelin	3.6 mg SC every 28 days	Hot flashes, amenorrhea, menopausal symptoms, injection-site reactions
Progestins	Megestrol acetate	40 mg PO 4 for a day	Weight gain, hot flashes, vaginal bleeding, edema, thromboembolism
	Medroxyprogesterone	400–1000 mg IM every week	

IM, intramuscular; LHRH, luteinizing hormone–releasing hormone; PO, oral; SC, subcutaneous; SERD, selective estrogen receptor downregulator; SERM, selective estrogen receptor modulator.

without pertuzumab avoids some of the risks and toxicities associated with anthracyclines. Furthermore, anti-HER2 therapy can be given concurrently with this regimen.

Neoadjuvant endocrine therapy may be an option for patients who have unresectable, strongly hormone receptor–positive tumors, low-risk factors, or are unable to receive chemotherapy because of comorbid medical conditions. Endocrine therapy is usually given for 4 to 8 months or until maximal response. Regardless of therapeutic approach, about two-thirds of the tumors can be downstaged; the pathological complete response rate is approximately 50%.

The extent of surgery will be determined by tumor response to neoadjuvant therapy, patient wishes, and cosmetic results likely to be achieved. Adjuvant anti-HER2 therapy improves the overall survival in patients with residual disease and should be administered.[21] Patients with HER2-negative breast cancer who do not achieve pathological complete responses (pCRs) following neoadjuvant chemotherapy have a high risk of relapse, especially those with TNBC. In the absence of any established adjuvant chemotherapy, a recent study demonstrated that 6 months of adjuvant capecitabine improved both the DFS and OS (though this is still not considered the standard of care).[22]

Patient Encounter, Part 4

Despite what appeared to be a small tumor on imaging, the multidisciplinary breast cancer team, in discussion with the patient, decided the best treatment strategy was systemic neoadjuvant therapy (SNT) followed by surgery and adjuvant therapy.

Discuss important aspects related to each component of the treatment plan including:

- *Selection of systemic agents and their toxicity profiles*
- *Extent of surgery*
- *Adjuvant therapy considerations*

METASTATIC BREAST CANCER (STAGE IV) TREATMENT

Desired Outcome

The goals of therapy for patients with metastatic breast cancer (MBC) are maintaining or improving quality of life and prolonging survival. In order to achieve these goals, an important consideration is selecting therapy with good activity and tolerability.

General Approach to Treatment

The choice of therapy for MBC disease is based on receptor expression status (ie, hormone and HER2) and distant disease sites. In many instances, age and comorbid medical problems will also be considered. While the choice between endocrine and cytotoxic chemotherapy is usually the hormone receptor status of the tumor, sites of metastatic disease may also influence treatment decisions. For example, in patients with ER-positive breast cancer with soft tissue or bone-only metastasis (without impending fracture), endocrine therapy alone is usually warranted. Hormonal therapy can even be considered in patients with asymptomatic visceral involvement. In contrast, chemotherapy is usually the initial treatment option for hormone-dependent breast cancer in patients who present with significant life-threatening metastasis to liver and/or lung. When used, chemotherapy is continued to maximal response. Patients with tumors responding initially to endocrine therapies are often treated with chemotherapy when endocrine options are exhausted or symptomatic visceral metastasis develops. Approximately 75% to 80% of tumors positive for both ER and PR respond to initial hormonal therapy; responses decrease to 50% to 60% for ER-positive/PR-negative tumors. The best predictor of response to second- and, possibly, third-line endocrine therapies is extent and duration of the initial response. Nevertheless, tumor responses are frequently lower and durations shorter with subsequent hormonal therapies.

KEY CONCEPT Endocrine therapy is not indicated for tumors that do not express at least one of the hormone receptors. Depending on functional status, patients with receptor-negative tumors should be treated with cytotoxic chemotherapy. Objective responses are achieved in 50% to 60% of patients who have not received prior chemotherapy though less than 20% of the responses are complete.

The duration of response to first-line therapy is usually less than 12 months. Although uncommon, responses to initial treatment can be extremely durable with patients living years without evidence of disease. The response rate to second- and third-line chemotherapy varies from 20% to 40%. Combinations of chemotherapy plus endocrine therapy are not used in the metastatic disease setting because of increased toxicity without added benefit.

Even though incurable, it has been recently reported that the 5-year relative survival rate has increased twofold from 18% to 36%. Notably, the improvement was observed primarily in women less than 50 years of age.

Pharmacologic Systemic Therapy

▶ *Endocrine Therapy*

The operative mode of all endocrine therapies is estrogen deprivation. The pharmacologic goal is to decrease the levels of circulating estrogen and/or prevent estrogen effect on tumor tissue through receptor blockade or downregulation. A number of new and effective agents are available. For postmenopausal women with hormone receptor–positive, HER2-negative MBC, an AI is recommended either alone or in combination with a cyclin-dependent kinase (CDK) 4/6 inhibitor as frontline therapy. Of note, the addition of palbociclib, ribociclib, or abemaciclib has demonstrated improvement in **progression-free survival (PFS)** and possibly, OS. One other biological target involves the PI3K pathway that is relevant because the development of acquired resistance remains a significant challenge. Activated in approximately 70% of all breast cancers, a recent study showed that an α-specific, PI3K inhibitor in combination with fulvestrant improved PFS in subjects with disease progressing on endocrine-based therapy.[23]

Until the turn of the century, evidence did not support the superiority of one type of endocrine therapy with regard to response or survival. Because of the similarity in efficacy, selection of endocrine therapy was based primarily on their toxicity profile (see Table 89–6), which favored tamoxifen. The only exception to this choice of therapy occurred in patients who received adjuvant tamoxifen and subsequently developed metastatic disease within 1 year of drug cessation.

Over the last 15 years, accumulating evidence related to the AIs has changed the way postmenopausal women with hormone-dependent MBC are treated. After menopause, estrogens continue to be produced by extragonadal conversion of androstenedione and testosterone to estrone and estradiol. This biosynthetic process, which is dependent on aromatase, occurs in peripheral tissue, including muscle, adipose, and even the breast itself. Therefore, AIs effectively reduce the level of circulating estrogens, as well as estrogens in the target gland. Their toxicity profile has been described in Chapter 88 and Table 89–6.

In general, the AIs are preferred as first-line therapy for ER-positive advanced breast cancer in postmenopausal women. Results of large clinical trials comparing these agents against tamoxifen demonstrated improved PFS among patients receiving AI therapy. A consistent observation in these trials was a lower incidence of thromboembolic events, endometrial cancer, and vaginal bleeding in patients treated with an AI. Of note also, several small studies indicated that regardless of which subclass of AI used initially, approximately 50% of the patients will have further antitumor benefit after switching to the other subclass suggesting that cross-resistance is incomplete. Therefore, postmenopausal patients may receive two AIs as first- and second-line therapies.

While the therapeutic benefit of the AIs is well accepted, targeted interruption of the cell cycle has been investigated to further enhance the treatment of patients with hormone-dependent MBC. The biological rationale is based on the critical role CDKs have in regulating phase transition related to cell cycle progression, cell division, and cell proliferation. Of the four stimulatory kinases, CDKs 4 and 6 are believed to be key promoters of tumor proliferation and hence, attractive targets for inhibition. Published results of three clinical trials demonstrating a significant reduction in risk of disease progression or death with combined CDK4/6 inhibitor plus AI compared to AI alone led to the recent approval of palbociclib with letrozole, and ribociclib or abemaciclib with any AI, as first-line therapy for ER-positive MBC in postmenopausal women.[24-26]

The use of AIs is approved for postmenopausal women. Even though ovarian estrogen production relies on the same enzymatic pathway discussed earlier, premenopausal or perimenopausal women with functioning ovaries are not appropriate candidates for these therapies. The reason is physiologic as evidence indicates that negative endocrine feedback will overcome aromatase inhibition. Clinical data also suggested that the strategy of combining an AI with ovarian suppression (ie, oophorectomy or luteinizing hormone–releasing hormone [LHRH] agonists) can also be considered in treatment-naïve premenopausal women.

Administration of AIs in men increases circulating levels of testosterone, which may antagonize the therapeutic effect of the drug. However, an AI plus gonadotropin-releasing hormone agonist with a CDK4/6 inhibitor is an option in men with **hormone receptor–positive** MBC.[27]

Antiestrogens bind to ERs, preventing receptor-mediated gene transcription, and therefore are used to block the effect of estrogen on the end target. This class of agents is subdivided into two pharmacologic categories, SERMs and selective ER downregulators (SERDs). SERMs like tamoxifen have tissue-specific estrogenic and antiestrogenic activities. The effort to minimize or eliminate the adverse estrogenic effects led to the development of SERDs, which are pure ER antagonists. The distinguishing feature of SERDs is their ability to degrade the ligand–ER complex.

Fulvestrant is the only SERD approved for clinical use in the United States. The drug received expanded indication as initial monotherapy for postmenopausal women with hormone receptor–positive, HER2-negative MBC.[28] However, clinical trial results have not consistently demonstrated improvements in PFS and OS with AI added to fulvestrant. The side-effect profile of fulvestrant is generally similar to the antiestrogens except for dermal reactions at the injection site. Even though fulvestrant is a good option for patients who are unable to take an oral medication, some patients may be averse to the drug because it must be given intramuscularly. There is no biological reason why fulvestrant should not produce similar outcomes in premenopausal women; however, safety or efficacy data are lacking.

Resistance to frontline therapy inevitably occurs in patients with advanced disease. One of the mechanisms of endocrine resistance appears to involve the mammalian target of rapamycin (mTOR), a protein downstream PI3K/Akt-signaling pathway. Results from a number of clinical trials demonstrated that everolimus, an mTOR inhibitor combined with an AI, tamoxifen, or fulvestrant is an effective treatment option for postmenopausal women with advanced disease.

Tamoxifen can be used in both premenopausal and postmenopausal women with ER-positive MBC. Toxicities associated with tamoxifen have been previously described. The only additional acute adverse effect, which occurs in about 5% of the patients with bone metastasis, is tumor flare or hypercalcemia following initiation of tamoxifen. Generally, this acute reaction is not an indication to discontinue treatment. Conversely, this finding appears to correlate with subsequent response to endocrine therapy.

Ovarian ablation or suppression in premenopausal women can be effectively achieved surgically or pharmacologically. Even though the efficacy of oophorectomy and tamoxifen are comparatively similar, secondary response rates to oophorectomy after tamoxifen treatment were somewhat higher than response rates achieved with tamoxifen after oophorectomy (33% vs 11%). Interpretation of these findings suggests that tamoxifen does not completely antagonize available estrogen, particularly in premenopausal women.

Castration can also be achieved pharmacologically with LHRH agonists. An initial surge in luteinizing hormone induces estrogen production, which can cause a tumor flare reaction similar to tamoxifen. Receptor downregulation occurs after a few weeks resulting in castrate levels of estrogen. With continued therapy, remission is achieved in about one-third of unselected patients. Of the three agents available in the United States, only goserelin is approved for the treatment of MBC.

Although tamoxifen alone can be considered, guidelines developed by the American Society of Clinical Oncology recommend offering ovarian ablation or suppression in combination with antiestrogen or AI in premenopausal women with endocrine-responsive MBC.

In randomized trials, progestins such as megestrol acetate and medroxyprogesterone acetate have been shown to induce noninferior response rates when compared with tamoxifen. Megestrol acetate is used more frequently in the United States. Despite their efficacy, these agents have been relegated to third-line status. The most common side effects are listed in Table 89–6. One side effect, weight gain, occurs in 20% to 50% of patients. Patients experiencing weight gain may have fluid retention, but fluid retention is not responsible for all of the weight gain. In cachectic cancer patients, the weight gain may be desirable, but this is not uniformly true of all patients with MBC.

High-dose estrogens and androgens are rarely used because they are more toxic than other hormonal agents and, in some cases, less effective. About one-third of patients placed on high-dose estrogens will discontinue the use of these agents because of side effects, the most important of which are thromboembolic events, vomiting, and fluid retention.

▶ *Cytotoxic Chemotherapy*

Except for brain and spine (with impending cord compression), chemotherapy is given as initial treatment of metastasis in patients with hormone receptor–negative tumors. The median time to an objective response is 2 to 3 months, but this period depends largely on the site of measurable disease. For example, time to response is 3 to 6 weeks for disease localized primarily to skin and lymph nodes; 6 to 9 weeks lung lesions; 15 weeks for liver metastasis; and 18 weeks for bone involvement. Once chemotherapy has been initiated, it is usually continued until maximal response, disease progression, or intolerable toxicity.

Unlike endocrine or anti-HER2 therapy, no clinical characteristic or established test has been shown to predict benefit from chemotherapy. However, a number of factors are associated with likelihood of tumor response, including good performance status, limited number (one or two) of disease sites, treatment-naïve status, and previous response to chemotherapy with a long disease-free interval. Tumors that progress while being treated may respond to different agents. Importantly, tumors that do not respond to endocrine therapy are as likely to respond to chemotherapy as tumors treated with cytotoxic agents first. If not used initially, chemotherapy can be an effective therapeutic option in appropriately selected patients with advanced breast cancer.

KEY CONCEPT The most active classes of chemotherapy in MBC are the anthracyclines and the taxanes with response rates as high as 50% to 60% in patients who have not received prior chemotherapy for metastatic disease. Although many chemotherapeutic agents have demonstrated activity in the treatment of breast cancer, the most frequently used agents include all of the agents used in the adjuvant setting. A brief discussion of the taxanes, capecitabine, and gemcitabine extends upon what is described in Chapter 88.

Taxanes

In the metastatic setting, the most effective weekly dose of paclitaxel is 80 to 100 mg/m^2 days 1, 8, and 15 of a 28-day cycle. With this approach, the toxicity profile of paclitaxel changes with less myelosuppression and delayed onset of peripheral neuropathy, but slightly more fluid retention and skin and nail changes.

A dose-response relationship has been demonstrated with docetaxel. The preferred regimen is 80 to 100 mg/m^2 given every 21 days. While less neuropathy, myalgia, and hypersensitivity reactions are observed with docetaxel (compared to paclitaxel), the incidence of febrile neutropenia, fluid retention, and skin reactions is higher. A weekly schedule of docetaxel, 30 to 40 mg/m^2 for 3 weeks followed by a week off may be more tolerable in some patients. Premedication with dexamethasone reduces the risk of hypersensitivity reactions and fluid retention associated with paclitaxel and docetaxel, respectively.

Antimetabolites

Capecitabine has activity against tumors progressing on anthracycline- and taxane-containing regimens. Moreover, the drug exhibits somewhat selective activity against cancer cells. This belief is supported by the presence of higher tumor cell levels of thymidine phosphorylase, the enzyme that catalyzes the final step in the conversion of capecitabine to 5-FU. In previously treated patients, capecitabine produced response rates of about 25%, which was impressive compared with other tested chemotherapy agents.

Gemcitabine is another agent that is used frequently in patients with advanced breast cancer. This nucleotide analogue has a unique mechanism of action and a favorable toxicity profile. As a single agent, response rates of nearly 40% have been achieved in the first-line setting. Response rates to gemcitabine monotherapy in the second- and third-line settings are approximately 18% to 26%. When combined with one other agent such as a taxane, vinorelbine, cisplatin, or an anthracycline, results of clinical studies consistently demonstrated higher efficacy than either single agent. In patients who have been exposed to an anthracycline and a taxane, gemcitabine appears to provide a similar benefit to capecitabine.

General Comments

Combination chemotherapy regimens are usually associated with higher response rates than single-agent therapies, but the higher response rates do not necessarily translate into significant differences in OS. The use of sequential single-agent therapy versus combination chemotherapy regimens has been debated widely for MBC. In the advanced disease setting, the least toxic approach is preferred when efficacy is considered equal. In clinical practice, patients who require a rapid response to chemotherapy (ie, those with symptomatic bulky metastases) often receive combination therapy despite the added toxicity. This decision is complex and should be made on an individual patient basis.

Because many patients receive adjuvant chemotherapy, regimens that are chosen for first-line use in the metastatic setting often are different from those used in the adjuvant setting with the following caveat. If the patient's cancer recurs more than 1 year after the end of adjuvant chemotherapy, the same agents may have activity in the metastatic disease setting.

▶ *Targeted Biologic Therapy*

Anti-HER2 therapies are only indicated for breast cancers that meet the definition for HER2 positivity (ie, 3+ by immunohistochemistry and/or *HER2* gene/chromosome 17 ratio ≥ 2 by fluorescence in situ hybridization).

Trastuzumab targets a specific extracellular epitope of HER2. Single-agent treatment with trastuzumab produces responses in approximately 15% to 20% of patients; the clinical benefit rate, which includes CRs, PRs, and stable disease, is nearly 40%. Trastuzumab has additive and perhaps synergistic activity with chemotherapeutic agents.[29] The issue regarding concomitant administration with other cytotoxic agents has been discussed previously.

The most notable adverse effects associated with trastuzumab include cardiac dysfunction, infusion-related hypersensitivity reactions, and pulmonary toxicity. Close monitoring for clinical signs and symptoms of heart failure is imperative. Although cardiac toxicity is usually reversible, some patients may require pharmacologic therapy. In addition, it is important to educate patients regarding the latter two adverse effects because they may occur up to 24 hours after the infusion and can be fatal if not treated promptly.

Three oral agents have been tested in clinical trials involving women with HER2-positive MBC. Lapatinib inhibits the intracellular kinase domains of HER2 and HER1 (epidermal growth factor receptor). A pivotal phase 3 clinical trial assessed the efficacy and safety of lapatinib plus capecitabine versus capecitabine alone in patients with disease progressing on trastuzumab. The trial was terminated early when a preplanned interim analysis indicated a significant reduction in the risk of disease progression that favored the combination arm. Of note, the incidence of brain metastasis was significantly lower in the lapatinib-treated group.[30] Neratinib, a pan-HER receptor blocker, was approved initially as extended adjuvant therapy (following completion of trastuzumab) in July 2017. Both drugs are approved in combination with capecitabine as third-line therapies for women with advanced disease. In April 2020, tucatinib was approved as part of a three-drug combination with trastuzumab and capecitabine as 3rd-line therapy for patients with metastatic HER2-positive breast cancer including those with brain metastases.

The side-effect profiles of these three tyrosine kinase inhibitors are similar. Diarrhea, especially with neratinib, is the most distressing untoward effect. Dyspepsia and rash occurred more frequently when these agents were combined with capecitabine. Importantly, cardiac toxicity in the phase 3 trials of both agents was minimal compared to trastuzumab.

Pertuzumab is another HER2-targeted agent. Although both pertuzumab and trastuzumab are monoclonal antibodies that block HER2-mediated signaling, a number of differences exist. First, each agent recognizes different extracellular epitopes. Second, the unique binding site of pertuzumab induces structural changes that hinder receptor dimerization. Theoretically, by inhibiting HER2 signaling initiated by ligand-activated HER1 or HER3, pertuzumab could provide even greater inhibition of HER2 signaling than trastuzumab. However, this does not appear to be case. In fact, compared to trastuzumab, pertuzumab has exhibited less activity. Based on results of a phase 3 clinical trial, pertuzumab was initially approved as first-line therapy (in combination with trastuzumab and docetaxel) for HER2-positive MBC.[31] The antibody received additional indications as part of the treatment regimens in the neoadjuvant and adjuvant settings. The most frequently reported adverse observed in clinical trials involving pertuzumab was diarrhea; cardiac toxicity was similar to, but does not appear to be increased when used concurrently with, trastuzumab.

One of the most significant limitations of cytotoxic chemotherapy is the lack of tumor specificity. Coupling target selectivity with the observation that trastuzumab's modest antitumor effect was substantially improved by the addition of chemotherapy led to the idea that antibodies could be used to deliver chemotherapy rather specifically to tumor cells. However, the efficacy of antibody–chemotherapy (drug) conjugates (ADCs) has historically been limited by variable expression of the target antigen, defective tumor cell uptake mechanisms, and unreliable linkers used in the conjugation process.

A novel therapeutic compound known as trastuzumab-DM1 (T-DM1, trastuzumab emtansine) has been developed that appears to have resolved all of the above issues. Because HER2 is overexpressed in approximately 15% to 20% of breast cancers, trastuzumab was identified as a reasonable vehicle for drug delivery. In order to improve the therapeutic index of the attached chemotherapeutic agent, a maytansine derivative was synthesized. The resulting maytansinoid, emtansine, was configured to have an easily cleavable linker to trastuzumab. The resulting ADC has the potential not only of retaining the antitumor properties of the individual agents but also maintaining a tolerable side-effect profile. T-DM1 is effective both for women with progressing disease and in the adjuvant setting.[32,33] A second ADC, fam-trastuzumab deruxtecan, was recently approved as third-line therapy for HER2-positive, metastatic breast cancer. Other HER2-targeted agents and immune checkpoint inhibitors are in clinical development and appear promising.[34-36]

▶ *Bisphosphonates*

The inclusion of bisphosphonates as part of standard adjuvant therapy should be considered for all postmenopausal women. For women whose breast cancer has metastasized to bone, bisphosphonates are recommended, in addition to chemotherapy or endocrine therapy, to reduce bone pain and fractures. Zoledronic acid, a potent bisphosphonate, is used most frequently. Although usually dosed every 4 weeks, a 12 weekly schedule has been reported to be noninferior.[37] Supplemental calcium and vitamin D are usually prescribed.

Local-Regional Control

▶ *Radiation Therapy*

Radiation is an important modality in the treatment of symptomatic metastatic disease. The most common indication for treatment with radiation therapy is painful bone metastases or other localized sites of disease refractory to systemic therapy. Approximately 90% of patients who are treated for painful bone metastases experience significant pain relief with radiation therapy. Additionally, radiation is an important modality in the palliative treatment of metastatic brain lesions and spinal cord lesions, which respond poorly to systemic therapy.

Patient Encounter, Part 5

Two months after the case above, the president of the Sierra Club, a woman 63 years of age, reported that she too has been diagnosed with invasive breast cancer after routine biennial mammography. Pathological evaluation indicated the tumor was positive for both ER and PR, HER2 negative, low tumor grade, and low proliferation index. Surgically, a total mastectomy was performed with sentinel node biopsy. Tumor was 2.1 cm at its widest margin, and sentinel node was negative for tumor. Final diagnosis was $T_2N_0M_0$ (stage 2, node-negative), hormone receptor–positive breast cancer. Her overall prognosis is very good. Even though the decision to receive systemic therapy following surgery is ultimately a patient's decision, appropriately used enhances the 5-year survival rate.

Detail the process regarding recommendations for adjuvant therapy in this patient focusing on:

- *Choice and duration of endocrine therapy*
- *Quality-of-life issues and treatment-related adverse events*
- *Clinical benefit of adding chemotherapy*
- *Supplemental supportive care measures*
- *Counseling regarding physical activity and weight gain*

OUTCOME EVALUATION

Early breast cancer is resected completely with curative intent and adjuvant chemotherapy and/or hormonal therapy plus trastuzumab with or without pertuzumab, in selected patients who are initiated to prevent a recurrence. During adjuvant chemotherapy, clinical and laboratory assessments to monitor patient tolerance to therapy-related toxicities are performed before each cycle of treatment. After completion of adjuvant therapy, patients are monitored every 3 months for the first few years after diagnosis, with intervals between examinations extended as time from diagnosis lengthens. Evaluation includes the following:

- Physical examination to detect breast cancer recurrence
- Annual mammography
- Symptom-directed workup
- Assess vitamin D status, especially in postmenopausal women

Patients with LABC are often treated with neoadjuvant therapy to enable tumor resectability. However, many believe that neoadjuvant therapy may have benefits that extend beyond downstaging. In addition, physical and ultrasound examinations are conducted to determine the size of the tumor following a complete course of neoadjuvant therapy. Surgical resection is then performed. Although no further chemotherapy is usually given following surgery, there is one confirmed exception, adjuvant T-DM1 and, possibly, capecitabine in patients with pathologically assessed residual tumor cells after preoperative chemotherapy. MBC is not curable, and therapy is intended to palliate symptoms and prolong survival. In most cases, hormonal therapy is the mainstay for tumors that are ER positive. While on therapy, patients are monitored monthly for signs of disease progression or metastasis to common sites, such as the bones, brain, or liver. Evaluations include the following:

- Pain
- Mental status or other neurologic findings
- Laboratory tests
- Liver function tests
- Complete blood count
- Calcium, electrolytes

Patient Care Process: Breast Cancer

Collect Information:

- Review medical/medication history and current laboratory values
- Document components of the medical history related to risk factors, breast cancer screening and surveillance programs, and menopausal status
- Discuss the overall health and performance status with the patient
- Address issues related to quality of life, psychosocial support, and survivorship needs
- Gather information related to insurance coverage

Assess the Information:

- Detail key aspects of the patient's history related to breast cancer risk level (ie, age, family history of breast/ovarian and other cancers, exposure to estrogens and ionizing radiation, and atypia)
- Determine the circumstance(s) that led to the diagnosis
- Determine the intrinsic subtype and stage of the disease
- Evaluate the overall prognosis for a patient with early breast cancer based on intrinsic subtype, stage, regional node status, proliferation markers, and tumor grade

Develop a Care Plan:

- Provide sufficient time for patient to process and cope with the diagnosis
- Explore the appropriateness of testing for possible hereditary cancers and fertility preservation in premenopausal women
- Assess treatment goals
- Formulate treatment strategy based on tumor burden, nodal involvement, tumor biology, health and menopausal status, and patient preference
- Identify key endpoints (especially with regard to quality-of-life issues) related to pharmacotherapeutic management of the patient
- Develop a supportive care plan

Implement the Care Plan:

- Ensure that the patient understands details related to the overall treatment plan (ie, timing and duration of systemic therapy relative to other treatment modalities)
- Assess pharmacologic treatment for drug interactions
- Address concerns and appraise comprehension and communication of drug-related side effects and possible adverse events (both acute and delayed)

(*Continued*)

Patient Care Process: Breast Cancer (*Continued*)

Follow-up: Monitor and Evaluate:

- Reinforce compliance regarding clinic visit and medications prescribed
- Address acute therapy-related complications and recommend or modify therapy as appropriate
- Recommend treatment of delayed therapy-related complications (ie, menopausal symptoms, and osteoporosis)
- Reeducate patient regarding any change(s) in medication(s)
- Assess quality-of-life issues especially for women receiving long-term endocrine therapy

Abbreviations Introduced in This Chapter

AI	Aromatase inhibitor
BCS	Breast-conserving surgery
CDK4/6	Cyclin-dependent kinases 4 and 6
ER	Estrogen receptor
HER2	Human epidermal–related growth factor receptor
HRT	Hormone replacement therapy
LABC	Locally advanced breast cancer
LHRH	Luteinizing hormone–releasing hormone
MBC	Metastatic breast cancer
PD-L1	Programmed death ligand 1 (PD1-binding protein)
PR	Progesterone receptor
SERD	Selective estrogen receptor downregulator
SERM	Selective estrogen receptor modulator
TNBC	Triple-negative breast cancer
TNM	Tumor, node, metastasis (staging system)

90 Lung Cancer

Ninh M. La-Beck and Christopher Selby

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify major risk factors for the development of lung cancer.
2. Explain the pathologic progression of lung cancer and its relationship with signs and symptoms of the disease.
3. Make appropriate recommendations for screening and preventive measures in high-risk patients.
4. Understand staging of lung cancer patients and how it influences treatment decisions.
5. Explain how histology, biomarkers, and genetic mutational testing are used to select therapy.
6. List the rationale, advantages, and disadvantages for neoadjuvant and adjuvant chemotherapy in non–small cell lung cancer (NSCLC).
7. Identify the treatment of choice and treatment goals for limited and extensive small-cell lung **carcinoma**.
8. Identify the treatment of choice and treatment goals for local, locally advanced, and advanced non–small cell lung carcinoma.

INTRODUCTION

Lung cancer continues to be one of the most commonly diagnosed cancers and the leading cause of cancer-related mortality. Although treatment can cure some patients, most therapies are aimed at prolonging survival and reducing symptoms. Recent advances in lung cancer research have provided a number of new targeted therapies that provide significant benefit for some populations of patients; however, prevention and risk-reduction still appear to be the best strategies for reducing lung cancer incidence and mortality.

EPIDEMIOLOGY AND ETIOLOGY

Incidence and Mortality

Lung cancer, including cancer of the bronchus, is the second most common cancer diagnosis in the United States behind breast cancer[1] and the number one cause of cancer-related mortality, comprising more than 25% of cancer-related deaths in the United States. A close correlation exists between incidence and mortality of lung cancer, reflecting the reality that approximately 80% of patients with lung cancer ultimately die of the disease.[1]

Risk Factors

▶ *Tobacco Smoke*

KEY CONCEPT The most important risk factor for the development of lung cancer is tobacco smoke. Although rates of lung cancer have nearly doubled in never-smokers over the past 25 years, this population still only represents about 15% of all cases while the remaining 85% of cases occur in current or former smokers.[2] The correlation between smoking and lung cancer continues to drive anti-smoking and clean indoor air campaigns. Both total smoke exposure (reported as pack-years where one pack-year is the equivalent of smoking one pack per day for 1 year) and current use correlate with the individual's risk of developing malignancy. The risk of lung cancer decreases over time after a patient stops smoking, with at least 5 years needed to see appreciable decreases in cancer risk.[3] However, a former smoker will never see their risk return to that of a nonsmoker. Therefore, smoking cessation plays an important role in reducing lung cancer risk, making this a critical element of lung cancer prevention and treatment in at-risk patients. In addition to direct inhalation of cigarette smoke, environmental tobacco smoke, also known as passive smoking, is thought to cause 3000 cases of lung cancer per year.[3]

▶ *Other Environmental Risks*

Other environmental risk factors include **radon**, arsenic, nickel, and carcinogens such as chloromethyl ethers and coal products. Radon is the second leading cause of lung cancer overall, and the leading cause in never-smokers.[4] Those who live in an urban environment are also at increased risk for lung cancer due to exposure to high concentrations of combustion fumes.[4] Asbestos exposure increases the risk of developing **mesothelioma**, a distinct and rare type of lung cancer.

▶ *Hereditary Risk Factors*

Although smoking is a key risk factor for lung cancer, the majority of smokers never develop lung cancer. It is likely that genetic risk factors exist that may predispose certain smokers to lung cancer. After adjustments for age, smoke exposure, occupation, and gender, relatives of a lung cancer patient have approximately a two-fold higher risk of developing lung cancer.[5] The degree of inherited risk inversely correlates with the age of the relative at the time of diagnosis. First-degree relatives of a lung cancer patient diagnosed between the ages of 40 and 59 years have a six-fold higher risk for lung cancer. Although familial lung cancer that develops at an early age in nonsmokers fits a Mendelian codominant inheritance model, no gene has been identified that is specific for lung cancer.

▶ *Uncertain or Unproven Risk Factors*

Smoking marijuana may increase the risk of lung cancer similarly to tobacco smoking. However, this has not been well-studied due to the illicit status of marijuana in most places and due to confounding factors, such as concurrent tobacco smoking. E-cigarettes, which deliver nicotine without tobacco or by-products of smoking, are relatively new and no long term studies are currently available. However, emerging studies suggest that e-cigarette products may contain high levels of heavy metals such cadmium and nickel which may be risk factors for lung cancer.

Chemoprevention

Many potential chemoprevention agents, including nonsteroidal anti-inflammatory drugs, retinoids, inhaled glucocorticoids, vitamin E, selenium, and green tea extracts have been studied.[6-8] However, none have met regulatory criteria for drug approval[8] and two large randomized trials found that beta carotene supplements may actually increase the risk of lung cancer in smokers.[9] Therefore there are currently no chemoprevention strategies for smokers.

Screening and Early Detection

The 5-year survival for patients diagnosed with localized lung cancer is greater than 60% whereas for regional and distant disease, 5-year survival rates are 35% and 6%, respectively.[10] Unfortunately, most patients have advanced disease at the time of diagnosis (Figure 90–1), therefore, improved early detection of lung tumors could improve overall survival.

The National Lung Screening Trial (NLST) randomized over 53,000 patients at high risk for lung cancer to three annual low-dose spiral computed tomography (CT) scans or chest X-rays.[11] Chest X-ray has been shown in large trials to be equivalent to no screening and can be considered a placebo control for mortality. In the CT screening arm, 6.9% of patients were diagnosed with localized lung cancer with over 90% having surgery with curative intent, resulting in a 20% reduction in lung cancer mortality compared to the control arm.[11] In this study, high-risk patients were defined as having all of the following criteria:

1. Age between 55 and 74 years old
2. If former smoker, had quit within the previous 15 years
3. Greater than or equal to a 30 pack-year history

While screening reduces lung cancer mortality, implementation has been slow. This is likely due to the small absolute change in mortality of 0.3% (1.3% vs 1.6%) combined with the high false positive findings.[11] In the NLST, the CT screening arm had positive findings in 26% of scans and nearly 40% of all patients, and 96.4% of the lesions discovered were benign (false positive).[11] Due to this high false positive rate, research continues to look for methods to improve the specificity of lung screening strategies.[12]

Based on these data, the United States Preventative Services Task Force guidelines give a category B recommendation (indicating moderate benefit) that CT screening be offered to high-risk patients in combination with tobacco cessation where applicable.[12]

PATHOPHYSIOLOGY

Histologic Classification

Most lung cancers arise from the respiratory epithelium and are classified as carcinomas. Based on histological characteristics, lung cancer is classified into two major types, small-cell lung cancer (SCLC) and non–small cell lung cancer (NSCLC), that have major differences in invasiveness, disease prognosis and treatment. Small-cell lung cancer represents about 15% of cases but has a significantly higher mortality rate than NSCLC, which accounts for about 85% of cases.[13] NSCLC is further categorized into three major histologic subtypes: squamous cell carcinoma, adenocarcinoma, and large-cell carcinoma. It is important to note that there are other rare lung malignancies and lung cancers may consist of multiple histologic subtypes. Furthermore, pharmacologic treatments may selectively kill different components of the tumor, resulting in a conversion of the remaining tumor to a different subtype. Therefore, tumor histological classification is critical for therapy selection and clinical staging at the time of

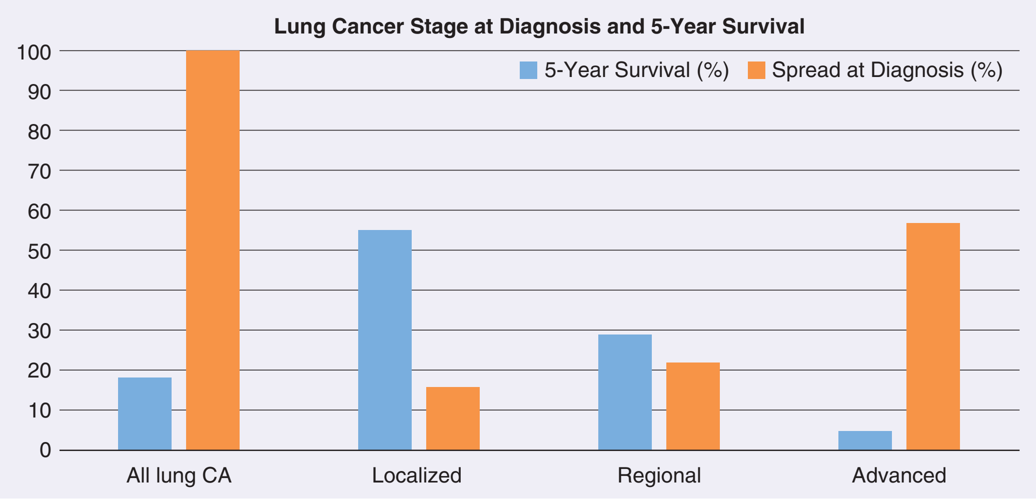

FIGURE 90–1. Lung cancer stage at diagnosis and corresponding 5-year survival in the United States. Data from National Cancer Institute. SEER Database https://seer.cancer.gov/statfacts/html/lungb.html accessed 8/14/2017.

Table 90–1

Lung Tumor Histopathology[14]

Tumor Type	Percent of Tumors	Targetable Mutation	Frequency
Small cell	15–20	None	
Non–small cell			
Adenocarcinoma	35–40	*EGFR*	15%–20%
		ALK	2%-7%%
		BRAF	3%–5%
		ROS1	1%–2%
		MET	1%-4%
		RET	1%–2%
		NTRK	<1%
Squamous (epidermoid)	25–30	Rare	
Large cell (giant)	10	None

diagnosis, and also after disease progression/recurrence in order to guide patient care decisions.

Molecular Classification

In addition to histology, tumors are described by the presence of driver mutations or biomarkers[14] as outlined in Table 90–1. All patients with metastatic disease and nonsquamous histology are tested for actionable oncogenes, eg, sensitizing epidermal growth factor receptor (EGFR), anaplastic lymphoma kinase 1 (ALK-1), ROS proto-oncogene 1 (ROS1), B-Raf proto-oncogene (BRAF), c-mesenchymal-epithelial transition factor exon 14 skipping mutation (MET), rearranged during transfection (RET) rearrangements, and neurotrophic-tropomyosin receptor kinase (NTRK; also referred to as neurotrophic tyrosine receptor kinase) gene fusions.[15] These driver mutations have a total prevalence of approximately 27% in newly diagnosed NSCLC patients with low overlapping probability (1%–3%).[16,17] In NSCLC, tumors with driver mutations or mutation/rearrangement of *ALK, BRAF, EGFR, MET, NTRK, RET,* or *ROS1* should be treated first line with molecular targeted therapies since they have been shown to improve response rates and survival compared to traditional cytotoxic therapies in this scenario.[16] Notably, targeted therapy can induce molecular changes in tumors that may lead to treatment resistance. Approximately 50% of NSCLC patients initially treated with EGFR targeting tyrosine kinase inhibitors (TKIs) (erlotinib, gefitinib, osimertinib, or afatinib) acquire resistance[18] leading to disease progression within 1 to 2 years in the majority of patients.[19]

It is estimated that 73% of NSCLC patients have oncogenic drivers that are not eligible for treatment with the currently approved molecular targeted therapies.[17] These patients are potentially eligible for immune checkpoint inhibitor (ICI) therapy targeting programmed cell death protein 1 receptor (PD-1), programmed death ligand 1 (PD-L1), or cytotoxic T-lymphocyte antigen 4 (CTLA4).[15] These checkpoints are immunoinhibitory coreceptors expressed on lymphocytes, myeloid immune cells, and tumor cells that are implicated in mediating cancer-associated immunosuppression and immune evasion.[20,21] Immune evasion is an emerging hallmark of cancer that involves upregulation of immune checkpoints such as the PD-1/PD-L1 pathway.[22] Blockade of this pathway using monoclonal antibodies against PD-1 or PD-L1, restored tumor-specific T-cell immunity and inhibited tumor growth in preclinical models.[22] Since then, evidence from multiple randomized trials have led to the approval of several immune checkpoint inhibitors for the treatment of lung cancer as monotherapy or as part of combination chemo-immunotherapy or dual immunotherapy regimen.[23-26] Although it involves monoclonal antibodies, it is considered separate from other antibody therapeutics because the goal is to activate the immune system to attack tumor cells, rather than the monoclonal antibody being directly responsible for cytotoxicity. A retrospective cross-sectional study found that about 40% of cancer patients were eligible for immunotherapy, with NSCLC patients accounting for about 20% of these patients.[27] Tumor PD-L1 expression and mutational testing should be performed on all NSCLC patients with metastatic disease who are considering systemic treatments.[15] Tumor mutational burden (TMB) is a measure of somatic nonsynonymous mutations,[28] and high TMB (10 or greater) is another indication for immunotherapy use.[28]

Patient Encounter Part 1

A 68-year-old man presents at your clinic complaining of worsening cough with occasional hemoptysis. He has had 1 to 2 severe upper respiratory infections annually for the past 4 to 5 years and 1 last month. He smoked about a pack of cigarettes per day beginning since he was 15 years old. He lives in a small rural town where he worked as a coal miner. A year after retiring at age 62 he purchased a restaurant/bar where he now works.

What risk factors for lung cancer are present?

Calculate this patient's pack-year history.

CLINICAL PRESENTATION AND DIAGNOSIS

The signs and symptoms of lung cancer depend on tumor location, size, and extent of invasion/metastasis. Tumors that are centrally located near the bronchus and trachea tend to present earlier with symptoms such as coughing, hoarseness (from tracheal compression), and dysphagia (from esophageal compression). In contrast, tumors that are peripherally located may not be symptomatic until lesions have progressed much longer. Nonetheless, the early clinical signs and symptoms of lung cancer are nonspecific and can also be attributed to other more common conditions such pulmonary or cardiovascular diseases. Consequently, 75% of patients will have advanced disease (regional and distant metastases) at the time of diagnosis.

KEY CONCEPT Signs and symptoms of lung cancer can be classified into three categories: pulmonary, extrapulmonary, and paraneoplastic syndromes. Distinguishing among these classes of symptoms is important in determining disease severity and prognosis, and guiding treatment selection.

Clinical Staging

The diagnosis of lung cancer is confirmed through visualization and biopsy (Table 90–2), then the extent of disease must be determined by clinical staging. Clinical staging serves two primary purposes: predicting prognosis and guiding therapy. Both NSCLC (squamous and nonsquamous subsets) and SCLC are staged using the American Joint Committee on Cancer (AJCC) tumor, node, and metastasis (TNM) staging system. However,

Clinical Presentation and Diagnosis[29]

Pulmonary Symptoms

Symptoms related to the direct effects of the primary tumor often appear first and are the most common. These include:

- Cough
- Chest pain
- Shortness of breath
- Pneumonitis
- Dysphagia
- Hemoptysis
- Hoarseness
- Pleural effusion

Extrapulmonary Symptoms

Once the tumor invades tissues outside the pleural cavity, it can produce a wide array of symptoms, including:

- General bone pain
- Adrenal insufficiency
- Confusion
- Personality changes
- Enlarged lymph nodes
- Weight loss
- Seizures
- Nausea and vomiting
- Focal neurologic symptoms
- Horner syndrome
- Fatigue
- Headache
- Pancoast syndrome
- Subcutaneous skin nodules

Paraneoplastic Syndromes

Symptoms that are not a result of the direct effects of the tumor are termed paraneoplastic syndromes. They may be caused by substances secreted by the tumor or in response to the tumor and often occur in tissues far from the site of malignancy. Paraneoplastic syndromes are numerous and affect a wide variety of systems, including the endocrine, neurologic, skeletal, renal, metabolic, vascular, and hematologic systems.

- Cushing's syndrome
- Hypercalcemia
- Syndrome of inappropriate secretion of antidiuretic hormone (SIADH)
- Hypercoagulable state
- Anemia

Diagnosis

Diagnosis requires visualization of one or more lesions as well as a biopsy to confirm malignancy. Both visualization and sampling can be performed by invasive or noninvasive methods. These methods are summarized in Table 90–2.

clinical staging, management and prognosis of these two types of lung cancer are distinct. Lung cancer diagnosis can be confirmed through a number of diagnostic biopsies including direct tissue biopsies via bronchoscopy, mediastinoscopy, and transthoracic fine needle aspiration or core sample. These tests all carry risk to the patient as they require a surgical procedure, typically under anesthesia, to confirm a lung cancer diagnosis, and some patients may not be physically fit enough to tolerate such procedures. Less invasive methodologies include cytology testing on samples collected from sputum or thoracentesis to look for cancerous cells.[15] The newest and least invasive form of testing is a plasma or liquid biopsy which is a PCR-based test that can detect tumor-associated mutations in circulating cell-free DNA. At this time, liquid biopsies are not recommended in lieu of traditional histologic diagnostics, but can be used to help identify targetable mutations in a minimally invasive way.[15]

▶ *Non–Small Cell Lung Cancer*

Clinical staging of NSCLC with the TNM system is based on the size of the tumor (T), extent of nodal involvement (N), and presence of metastatic sites (M). Clinical stages are grouped together as localized, regional, or metastatic disease for real world prognosis by the National Cancer Institute Surveillance Epidemiology and End Results (SEER) Database. Local disease (stages 1 and 2) includes tumors that are confined to a single hemithorax and those cancers which have spread to the ipsilateral hilar lymph nodes. Once malignancy invades the mediastinal lymph nodes or contralateral hilar nodes, the disease becomes locally advanced (regional, stage 3). When lung cancer is detected outside the pleural cavity, it is considered advanced metastatic disease (stage 4). Local disease is associated with the highest cure and survival rates, whereas those with advanced disease have a 5-year survival rate of less than 5%.[10]

▶ *Small-Cell Lung Cancer*

The staging system for SCLC, originally developed by the Veterans Administration Lung Cancer Study Group, has now been incorporated into the TNM staging system.[30] This system categorizes SCLC into two classifications, limited disease or extensive disease, that guide treatment.

- Limited disease: Stages I to III that can be treated with definitive radiation therapy.
- Extensive disease: Stage IV or T3 and T4 characterized by multiple tumor/nodal lesions that are too extensive for a single radiation field.

TREATMENT

General Treatment Considerations

The treatment of lung cancer depends on tumor histology, stage of disease, biomarkers (eg, driver mutations, PD-L1 expression), patient characteristics and comorbidities, and performance status (PS). Treatment modality based on histology and stage is outlined in Figure 90–3. In the development of a patient care plan, the ultimate goals of therapy should be determined and treatment decisions made based on discussions between the treatment team and a well-informed patient. Some treatments may prolong survival by a few months, but at the expense of significant decrease in patient quality of life. Approximately half of patients diagnosed with NSCLC are greater than 70 years old[31] and compared to patients greater than 65 years old, they have more complex disease presentation with physiological changes and comorbidities[32,33]

Table 90–2

Diagnostic Tools[75,76]

	Technique	Description
Visualization	Chest X-ray	The least expensive visualization method in the diagnosis of lung cancer. Readily accessible and does not require systemic administration of contrast dye. However, it often detects lesions that are not cancerous and is not capable of assessing lymph node status.
	CT	More accurate when providing information on size, location, and invasion than chest radiography. It is recommended as part of the standard workup in most cases.
	PET scanning	Uses a substance called 5-FDG to produce a functional image of the lungs. Cells that are actively growing and dividing use greater amounts of glucose and therefore take up more 5-FDG. Focal regions of fluorescence can be visualized in cancerous lesions. PET scanning combined with a CT scan is more accurate than CT scan alone; however, the exact role of PET scanning in staging and monitoring is unclear. The apparent benefit and common role in staging is to evaluate mediastinal disease when it can influence the tumor resectability.
Tumor sampling	Fine needle aspiration	A method of aspirating cells from the tumor via insertion of a small-bore needle into the lesion and aspirating. Commonly used to evaluate lymph nodes or other poorly accessible sites, it has the advantage of being faster and less invasive than other biopsy methods; however, it does not preserve the architecture of the tumor and may return cells that are undergoing cell death, which negates histologic analysis.
	Bronchoscopy	A fiberoptic camera is inserted through the airways to examine the site of the suspected lesion. Once the lesion is visualized, a tool attached to the camera allows for a tissue biopsy. Newer technologies incorporate fluorescence to differentiate malignant tissue from premalignant lesions.
	Core needle biopsy	A method of obtaining tissue and preserving the tumor architecture. A large-bore needle is inserted into a lesion, where it cuts a core of tissue out that then can be evaluated.
	Liquid Biopsy	A method in which a peripheral blood sample is assessed for the presence of cancer biomarkers and oncogenes. This is considerably less invasive than direct tumor sampling, but is not yet considered to be as reliable as conventional sampling.
	Thoracentesis	Involves removal of fluid in the pleural cavity via a needle. The fluid then is assayed for the presence of cancerous cells. This procedure has low sensitivity and depends on the presence of a pleural effusion.
	Sputum cytology	Detects cancerous cells that become dislodged from the airways into the sputum. Sputum cytology is useful because it is not invasive, but it has much lower sensitivity for detecting cancer.

CT, computed tomography; 5-FDG, 5-fluorodeoxyglucose; PET, positron-emission tomography.

that may affect response to therapy and/or increase risk of adverse effects. KEY CONCEPT In patients with early stage disease, a definitive cure is the primary goal of treatment, although this end point is not always met. Additional goals of treating lung cancer patients include prolongation of survival and improvement of quality of life through alleviation of symptoms.

▸ *Performance Status*

The Eastern Cooperative Oncology Group (ECOG) performance status (PS) (see Chapter 88) is an independent prognostic indicator for survival in patients with lung cancer.[34] The performance status (PS) also predicts response and likelihood of toxicity to chemotherapy. Patients with localized disease tend to be treated with more aggressive measures as the intent of treatment is curative. However, these aggressive treatments also increase the risks of treatment related adverse events, some of which can be dose-limiting or fatal. Patients with good PS (0–1) are more likely to tolerate the full treatment intensity, while patients with PS 2 may require dose reductions or experience treatment delays due to adverse events. Patients with PS 3 to 4 usually receive palliative therapy and/or supportive care.

KEY CONCEPT Categorizing patients by their ECOG PS allows for a standardized approach to predict the capability to tolerate systemic therapies that have significant drug toxicities.

Treatment Modality

▸ *Surgery (NSCLC)*

KEY CONCEPT Of all treatment modalities, surgical resection is associated with the greatest improvement in survival for patients with early stage NSCLC tumors (clinical stage IA, IB, or IIA). Surgery is not recommended in locally advanced and metastatic disease as it has not been proven to prolong survival. However, surgery for advanced disease is an important palliative treatment that can improve quality of life in some patients. In this respect, surgery is limited to local sites where the tumor is causing significant morbidity (eg, spinal cord compression).[15]

▸ *Surgery (SCLC)*

Historically, patients with SCLC were rarely treated with surgery as the results of a randomized trial published in 1969 showed that surgery did not result in any 5- or 10-year survivors in comparison to radiation which produced a 4% survival rate at 5 and 10 years.[35] More recently, a retrospective study was published in 2018 showing that patients with limited stage SCLC who received surgery with adjuvant chemotherapy were found to have increased overall survival at 5 years (47.6%) as compared to patients who received concurrent chemoradiation (32.5%).[36] With improved imaging, surgical techniques, and better application of pharmacotherapy these numbers are significantly improved compared

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnosis

PMH: Moderate hypertension (controlled)

FH: Father died from lung cancer at age 62, mother is 85, alive, and living in a nursing home due to heart failure and dementia

Meds: Lisinopril 20 mg daily

ROS: (+) Chest pain, shortness of breath, hemoptysis; (–) recent weight loss

PE:

VS: BP 125/69 mm Hg, RR 26 breaths/min, P 80 beats/min, T 99°F (37.2°C)

CV: RRR

Labs: Slightly elevated LFTs and platelets, mild anemia (Hgb 11.8 g/dL); all others WNL; CXR reveals a solitary nodule in right lobe; fine needle aspiration confirms squamous cell carcinoma of the lung that stains positive for PD-L1; further evaluation with CT and PET scans reveal a 3-cm mass, with bilateral mediastinal lymph node involvement and a lesion on his adrenal gland.

What clinical stage is this patient's disease?

What is the estimated survival time for this stage of NSCLC?

Does this patient have any factors that may negatively or positively influence survival?

to the data from the 1960s. However, the review did note that only 30% of SCLC patients in the study received surgery while 70% were treated with chemoradiation, suggesting that we may be able to continue to improve upon the 5-year overall survival numbers for this patient population.

▸ *Radiotherapy (NSCLC)*

Patients with localized NSCLC are best treated with surgery, however, many of these patients are considered inoperable due to comorbidities (eg, lung disease from smoking).[37] In these situations, radiation therapy can be used with curative intent in place of surgery, and the success rate is approximately 50% that of surgery.[38] Patients with locally advanced (stage IIIB, nonsurgically resectable) disease have prolonged survival with combined chemotherapy and radiotherapy, while patients with metastatic NSCLC can receive radiation therapy to palliate symptomatic metastases. Although radiation is less invasive than surgery, it is associated with significant toxicities affecting normal tissue in the radiated area. Patients may experience esophagitis, pneumonitis, cardiac abnormalities, myelosuppression, and skin irritation. These adverse events can be decreased by using stereotactic radiation and/or hyperfractionated administration.[39]

Postoperative radiotherapy (PORT) is thought to eliminate remnants of the resected tumor that might be deposited in nearby tissue, but is only recommended for patients with positive margins after surgical resection when a local recurrence is of concern.[15]

▸ *Radiotherapy (SCLC)*

Radiotherapy, with concurrent chemotherapy, is the treatment of choice for limited-stage SCLC. Radiation may also be used for extensive-stage patients for symptomatic management. Limited- and extensive-stage SCLC patients who respond to therapy should also receive prophylactic cranial irradiation, which treats micrometastatic disease in the CNS. This improves cure rates for limited-stage disease and prolongs survival for extensive-stage disease.[37]

▸ *Systemic therapy (NSCLC)*

Traditional cytotoxic chemotherapy is the mainstay of lung cancer treatment for patients with locally advanced disease (ie, stage IIb or IIIa) although osimertinib was recently approved for patients with early stage EGFR mutant disease. In advanced or metastatic disease (stage IV), patients who are eligible for immunotherapy or whose tumors express a targetable mutation are treated first with targeted therapies. Cisplatin and carboplatin are considered the most effective traditional chemotherapy agents regardless of histology and are combined with a second agent to comprise a regimen known as a "platinum doublet".[14] **KEY CONCEPT** Platinum doublet chemotherapy offers superior response rates compared with single-agent chemotherapy regimens and should be used when the patient can tolerate the increased toxicity of multiple agents. Effective chemotherapy agents that may be combined with a platinum agent include paclitaxel, albumin bound paclitaxel, docetaxel, gemcitabine, vinorelbine, etoposide, and pemetrexed. Patients with squamous histology do not benefit from pemetrexed, while they seem to benefit more from gemcitabine (see Table 90–3 for regimen details). The duration of therapy has also been intently studied. Doublet therapy is generally given for four to six cycles; patients with nonsquamous histology receive benefit from maintenance therapy with pemetrexed with or without bevacizumab. Those with squamous histology can be treated with maintenance gemcitabine.[15]

PD-1 and PD-L1 inhibitors have become a mainstay in advanced NSCLC treatment. Pembrolizumab, targeting PD-1, is approved for first-line therapy both as monotherapy in PD-L1 positive patients, and in combination with chemotherapy regardless of PD-L1 expression. Atezolizumab, targeting PD-L1, is approved first-line for NSCLC regardless of PD-1 expression when used in combination with chemotherapy and bevacizumab, an antibody against VEGF.[40,41] Durvalumab, targeting PD-L1, was recently approved as consolidation immunotherapy after definitive platinum-based chemoradiation in unresectable stage 3 NSCLC.[15] Nivolumab (PD-1 target), atezolizumab, and pembrolizumab are also efficacious as second-line therapy. Key studies are shown in Table 90–4.

TKIs are the front-runners in molecular-targeted therapy for advanced NSCLC. Monotherapy with a TKI in genetically selected patients frequently outperforms cytotoxic chemotherapy. Multiple agents are approved for *EGFR, BRAF, and MET* mutations, *ALK, ROS1*, and *RET* rearrangements, and *NTRK* gene fusions. These TKIs are oral medications. Optimizing outcomes requires clinicians to obtain a complete medication history and be knowledgeable about preventing and managing therapy-induced toxicity (see Chapter 88) and drug interactions. Everyone involved in this process should be knowledgeable about toxicity prevention and management.[15] Results of key studies for targeted therapies are shown in Table 90–5.

Monoclonal antibodies targeting vascular endothelial growth factor (VEGF) signaling (bevacizumab and ramucirumab) and epidermal growth factor receptor (EGFR; necitumumab) have

Table 90–3

Select Chemotherapy Regimens and Their Efficacy

Regimen	Histology	Comparison	PFS	OS
		NSCLC Adjuvant Therapy[77]		
Cisplatin-vinorelbine (JBR.10)		Cisplatin 50 mg/m^2 IV day 1 and 8 q4 week × 4 weeks Vinorelbine 25 mg/m^2 IV day 1 q3 week for 16 weeks vs Observation		Median 7.8 years vs 6.1 years (P = 0.05)
		NSCLC First-Line for Advanced Disease[78-82]		
Cisplatin-paclitaxel	Not reported	Paclitaxel 135 mg/m^2 CIV over 24 h day 1 + cisplatin, 75 mg/m^2 IV day 2 repeat q3 week	Median 3.4 months vs	Median 7.8 months vs
Cisplatin-docetaxel		Cisplatin 75 mg/m^2 IV day 1 and docetaxel 75 mg/m^2 IV day 1 repeat q3 week	3.7 months vs	7.4 months vs
Cisplatin-gemcitabine		Cisplatin 100 mg/m^2 IV day 1 and gemcitabine 1000 mg/m^2 IV days 1, 8, and 15 repeat q4 week	4.2 months vs	8.1 months vs
Carboplatin paclitaxel (ECOG 1594)		Carboplatin AUC 6 IV day 1 and paclitaxel 225 mg/m^2 IV over 3 hours day 1 repeat q3 week	3.1 months (P = NS)	8.1 months (P = NS)
Cisplatin-pemetrexed	Squamous and nonsquamous	Cisplatin 75 mg/m^2 IV day1 + Pemetrexed 500 mg/m^2 IV day 1 Repeat q3 week × 6	Median 4.8 months vs	Median 12.6 months (adenocarcinoma) (P = 0.03) 9.4 months (squamous)
Cisplatin-gemcitabine		Cisplatin 75 mg/m^2 IV day 1 + Gemcitabine 1250 mg/m^2 IV days 1 and 8 Repeat q3 week × 6	5.1 months (P = NS)	Median 10.9 months (adenocarcinoma) 10.8 months (squamous) (P = 0.05)
Carboplatin-pemetrexed	Nonsquamous	Carboplatin AUC 6 IV day 1 + Pemetrexed 500 mg/m^2 IV day 1 Repeat q3 week	5.7 months vs	10.5 months vs
Oxaliplatin-pemetrexed		Oxaliplatin 120 mg/m^2 IV day + Pemetrexed 500 mg/m^2 IV day 1 Repeat q3 week	5.1 months (P = NS)	10.5 months (P = NS)
Carboplatin-albumin-bound paclitaxel	Squamous and nonsquamous	Carboplatin AUC 6 IV day 1 + albumin-bound paclitaxel 100 mg/m^2 IV days 1, 8, 15 Repeat q3 week	6.3 months vs	12.1 months vs
Carboplatin-paclitaxel		Carboplatin, AUC 6 IV day 1 + Paclitaxel 200 mg/m^2 IV over 3 hours day 1 Repeat q3 week	5.8 months (P = NS)	11.2 months (P = NS)
Carboplatin-paclitaxel +/– Bevacizumab (ECOG 4599)		Paclitaxel 200 mg/m^2 IV Day 1 + Carboplatin AUC 6 IV Day 1 Repeat q3 week × 6 vs Paclitaxel 200 mg/m^2 IV Day 1 + Carboplatin AUC 6 IV Day 1 + Bevacizumab 15 mg/kg IV day 1 Repeat q3 week × 6	Median 4.5 months vs 6.2 months (P < 0.001)	Median 10.3 months vs 12.3 months (P = 0.003)
		SCLC First-Line Regimens[83,84]		
Limited stage				
EP	Etoposide 100 mg/m^2/d IV days 1–3 + Cisplatin 80 mg/m^2 IV day 2 + Radiation Repeat q4 week vs		Median 1.1 year vs	Median 3.2 years vs
IP	Irinotecan 60 mg/m^2 IV days 1, 8, 15 + Cisplatin 60 mg/m^2 IV day 1 Repeat q4 week		1.0 year (P = 0.74)	2.8 years (P = 0.70)
Extensive stage				
Carboplatin-etoposide-atezolizumab	Etoposide 100 mg/m^2/d IV days 1–3 + Carboplatin AUC 5 IV day 1 + Atezolizumab 1200 mg day 1 Repeat q3 week x 4 followed by Atezolizumab 1200 mg day 1 Repeat q3 week vs		Median 5.2 months vs	Median 12.3 months vs
Carboplatin-Etoposide	Etoposide 100 mg/m^2/d IV days 1–3 + Carboplatin AUC 5 IV day 1 Repeat q3 week × 4–6		4.3 months (P = 0.02)	10.3 months (P = 0.007)
Platinum-Etoposide-Durvalumab	Carboplatin AUC 5–6 OR Cisplatin 75–80 mg/m^2 IV day 1 + Etoposide 100 mg/m^2/d IV days 1–3 + Durvalumab 1500 mg day 1 Repeat q3 week x 4 followed by Durvalumab 1500 mg day 1 Repeat q4 week vs			Median 13 months vs

been combined with traditional chemotherapy to improve outcomes. Their use is currently limited to stage IV NSCLC.

Therapeutic decisions must include the full consent and understanding of risks by the patient. Counseling on the therapeutic regimen and risk of toxicity is imperative before dosing. Refer to Chapter 88 for dosing recommendations in renal and hepatic failure.

▶ *Systemic therapy (SCLC)*

A platinum-based doublet regimen, either carboplatin or cisplatin combined with etoposide, is the cytotoxic chemotherapy backbone of treatment for SCLC. With limited-stage disease, cisplatin is thought to be slightly more efficacious than carboplatin, but also more toxic. The preferred treatment regimen for extensive-stage disease is four to six cycles of a platinum agent in combination with etoposide and an ICI, either atezolizumab or durvalumab, followed by maintenance therapy with the ICI.[37] If ICI therapy is contraindicated, carboplatin with etoposide, or cisplatin combined with irinotecan or etoposide, are acceptable alternatives. While molecular targeted therapies such as those targeting VEGF and EGFR have been investigated in SCLC, they have not been found to significantly improve outcomes.

Treatment of Non–Small Cell Lung Cancer

The first step in treatment of NSCLC involves confirmation of the clinical stage, histological subtype, and determination of likelihood of resection of the tumor. All patients should undergo histological evaluation since the subtype will impact clinical management. Moreover, patients with advanced (nonresectable) disease should also undergo genetic and biomarker analysis in addition to their histologic classification. PD-L1 testing needs to be done on all tumors in this setting, while the genomic analysis of driver mutations is required in nonsquamous NSCLC subtypes (adenocarcinoma and large cell). Mutation testing should also be considered in never smokers with squamous NSCLC. Treatment options depend on the stage of disease (ie, eligibility for resection), performance status, histology (squamous versus nonsquamous NSCLC), PD-L1 expression, and genetic findings.[15]

▶ *Local Disease (Stages IA, IB, and IIA)*

Local disease encompasses stages IA through IIA and is associated with a favorable prognosis. Approximately 60% of these patients are expected to live more than 5 years from time of diagnosis. The goal of therapy is curative in local disease, and surgery is the mainstay of treatment regardless of histology. Stage IA tumors are rarely seen clinically and may be treated with surgery alone. If surgical margins are positive, radiotherapy or repeat resection is recommended.[15] Stage IB and IIA may be treated with adjuvant chemotherapy, if surgical margins are positive for disease or if they are particularly high-risk patients. The rationale behind adjuvant chemotherapy is to eradicate micrometastases or other tumor cells that may have been missed during removal of the primary tumor. The results of five prospective trials suggest that there is benefit from adjuvant chemotherapy leading to a survival advantage of 4% to 15%.[42,43] Consequently, adjuvant therapy has become the standard of care in resectable NSCLC and should be offered to patients, particularly those with stage II or III disease.

Although the regimen of choice is unclear, studies evaluating pemetrexed in squamous NSCLC indicate that it has minimal to no activity in this histology. Thus, regimens containing pemetrexed should be avoided in patients with squamous NSCLC, regardless of stage. Cisplatin and vinorelbine regimens appear to have the most evidence supporting efficacy, regardless of histology or genetics. Carboplatin-based regimens may be used in patients unable to tolerate cisplatin or with comorbidities precluding cisplatin use.

▶ *Locally Advanced Disease (Stages IIB and IIIA)*

Patients with locally advanced disease should also be considered for surgery, followed by adjuvant chemotherapy as outlined in local disease. However, neoadjuvant chemotherapy could also be considered before surgery. The rationale behind neoadjuvant chemotherapy is to decrease the size of the tumor so that it can be resected more easily with clean margins, as well as to eliminate distant micrometastases before invasive local treatment. A meta-analysis of neoadjuvant trials suggests that neoadjuvant chemotherapy in all early stages improves 5-year survival by 5%.[44] Notably, in many of these studies, there was no adjuvant chemotherapy, which could theoretically improve survival to a similar extent as neoadjuvant chemotherapy. One concern with neoadjuvant chemotherapy is that the toxicity of these regimens may delay surgery, and if the tumor does not respond to the treatment, there is a risk of disease progression. However, current data suggest that more than 90% of patients who are treated with neoadjuvant chemotherapy maintained their scheduled surgery.[45] The utilization of neoadjuvant chemotherapy is inconsistent, but is most common in patients with locally advanced tumors (stage III).[46] Neoadjuvant chemotherapy regimens are platinum-based doublets. Three cycles of carboplatin and paclitaxel administered on a 3-week schedule is a common and supported approach. The benefit of combining neoadjuvant chemotherapy and surgery with additional adjuvant chemotherapy is being investigated but is of unknown value at this time. Relatively small studies have compared using three treatment modalities (chemotherapy, radiation, and surgery) to two treatment modalities (chemotherapy and radiation). Improvements have been shown for progression-free survival, but not overall survival. Consequently, the value of trimodal therapy is unclear.

▶ *Advanced or Metastatic Disease (Stages IIIB, IIIC, and IV)*

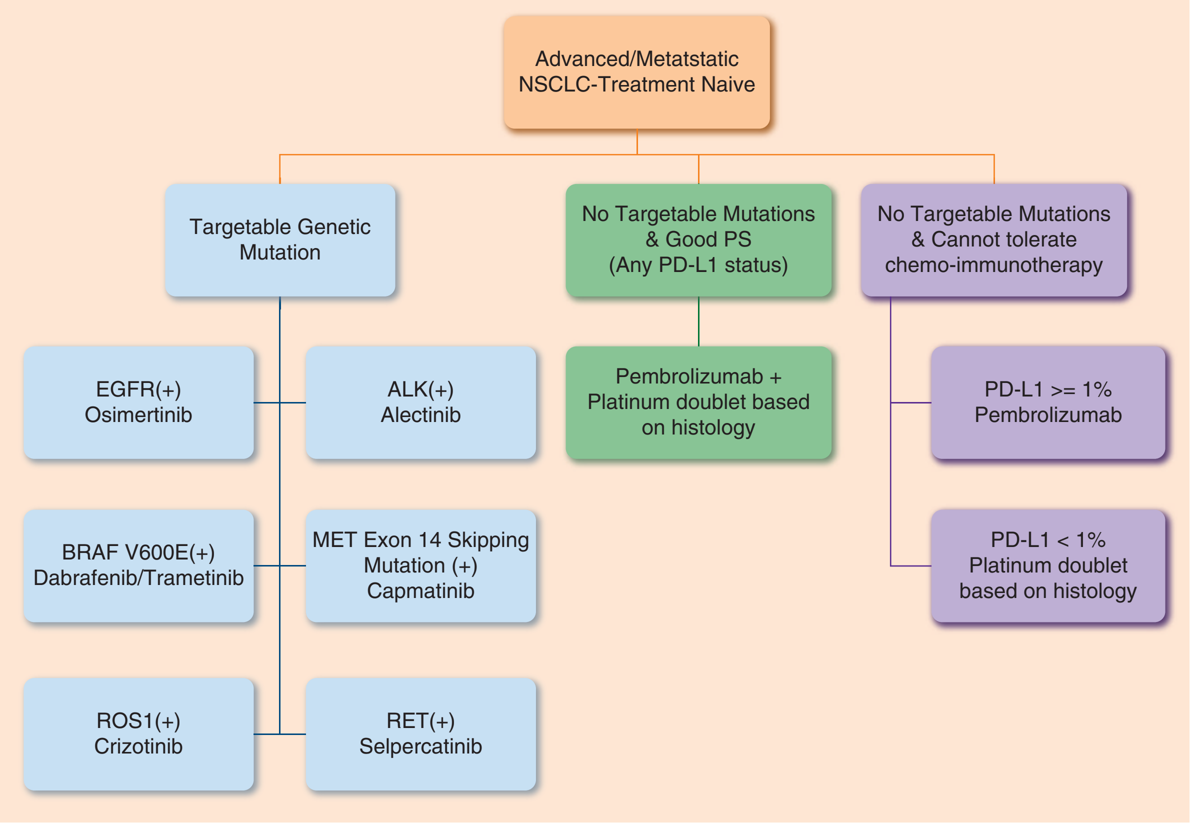
Advanced disease is treated with systemic therapy if the patient has an acceptable performance status. The selection of therapy is determined by the stage, histology, presence/absence of biomarkers/targetable mutations, and patient characteristics. Tumor PD-L1 expression and mutational analysis should be performed since these will determine selection of the treatment regimen. Patients with targetable tumor mutations do significantly better with a molecular-targeted agent than with traditional chemotherapy or immunotherapy. Currently, there are seven families of targetable mutations that have been reported in NSCLC: (a) *EGFR*, (b) *ALK*, (c) *BRAF*, (d) *ROS1*, (e) *MET*, (f) *RET*, (g) *NTRK*; they occur almost exclusively in nonsquamous histologies and are generally mutually exclusive. The *EGFR* activating mutations (most commonly exon 19 deletion and exon 21 substitution) are present in about 15% of nonsquamous tumors, *ALK* mutations (most commonly *ALK-EML4* rearrangement) are found in about 7% of nonsquamous NSCLC, while *BRAF* (most commonly V600E), *ROS1*, *MET* (most commonly exon 14 skipping mutation), *RET*, and *NTRK* mutated tumors are all less common, appearing in <5% of NSCLC patients.[15] Once patients fail appropriate targeted therapies, treatment options are similar to first-line treatment for no driver mutation (consider PD-L1 status and histology) (Figure 90–2).

EGFR mutation positive patients should be treated with osimertinib, afatinib, dacomitinib, erlotinib, or gefitinib in the first-line setting. In large randomized trials they have all been shown to be superior to chemotherapy with a median PFS of about 11 months. Osimertinib was recently compared to erlotinib and gefitinib in the first-line setting of *EGFR*-mutated NSCLC. Osimertinib demonstrated superior progression-free survival (18.9 vs 10.2 months) with fewer serious adverse effects, therefore it is now considered the preferred first-line agent.[15,47] Ultimately, all patients have a recurrence and the most common acquired mutation conveying resistance to EGFR-targeted TKIs is *T790M*. Upon recurrence patients should be tested for this mutation and those who are positive should be treated with osimertinib, which is active against this gatekeeper mutation, if they have not received osimertinib in the first-line setting. A prospective randomized trial compared second-line osimertinib to a platinum doublet. The results showed that osimertinib was superior in terms of ORR (71% vs 31%) and PFS (10.1 vs 4.4 months); however, the overall survival data were not mature at the time of analysis.[48]

ALK mutation positive patients should be treated with alectinib. Recently second-generation alectinib was studied head to head with crizotinib and demonstrated superiority. The median PFS with crizotinib was just 10.4 months (similar to previous trials), compared to 25.7 months with alectinib.[49] Moreover, the 5 year survival rates were 63% and 46% for alectinib and crizotinib, respectively. Ceritinib, another second-generation ALK inhibitor was approved as first-line therapy based on a trial showing its superiority to chemotherapy. In that trial the ceritinib PFS was 16.6 months.[50] Brigatinib is approved as second-line therapy for patients who have failed crizotinib.[51] *In vitro* studies suggest that it is active against resistance mutations, but the clinical significance of this is unknown. Lorlatinib is the most recently approved ALK inhibitor and demonstrates activity against resistance mutations and has good CNS penetration to reach brain metastases.[52] Ceritinib, alectinib, brigatinib, and lorlatinib are all approved as second-line options and the selection of therapeutic agent should be based on avoiding the agent used in the previous line of therapy.

A small number of lung cancer patients (~1%) harbor a mutation in *BRAF*, where dabrafenib with trametinib are indicated. A pivotal single arm, phase II trial enrolled 57 previously treated patients and reported an overall response rate of 63%. The progression-free survival for this trial was 9.7 months with a median duration of response of 9 months. Although large randomized trials are lacking, nonrandomized comparison of dabrafenib to dabrafenib plus trametinib support the combination based on ORR (27% vs 63%), and duration of response (9.9 vs 12.6 months).[53,54] For this population, dabrafenib with trametinib is recommended to be used first line. The other *BRAF* and *MEK* inhibitors do not have enough data to be used in this setting at this time. When patients fail dabrafenib and trametinib, they should be treated similarly to patients with no targetable mutations (Figure 90–2).

The *NTRK* driver mutation is found in less than 0.5% of NSCLC patients, but is targetable by tropomyosin receptor kinase (TRK)



Advanced/Metatstatic NSCLC-Treatment Naive
Targetable Genetic Mutation
No Targetable Mutations & Good PS (Any PD-L1 status)
No Targetable Mutations & Cannot tolerate chemo-immunotherapy
EGFR(+) Osimertinib
ALK(+) Alectinib
BRAF V600E(+) Dabrafenib/Trametinib
MET Exon 14 Skipping Mutation (+) Capmatinib
ROS1(+) Crizotinib
RET(+) Selpercatinib
Pembrolizumab + Platinum doublet based on histology
PD-L1 >= 1% Pembrolizumab
PD-L1 < 1% Platinum doublet based on histology

FIGURE 90–2. First-line treatment algorithm with preferred agents for advanced stage NSCLC based on biomarkers, genetic mutations, and histology. (NSCLC, non–small cell lung cancer; PD-L1, PD-1 targeting immunotherapy; EGFR, Epidermal Growth Factor Receptor; ALK, Anaplastic Lymphoma Kinase; MET, C-mesenchymal-epithelial transition factor; RET, rearranged during transfection.)

inhibitors. The presence of *TRK* mutations in other tumor types, including salivary gland cancers, sarcomas, and thyroid cancers, led to the FDA approval of larotrectinib for any *TRK* mutation positive cancers, making it the first oral anticancer therapy with an indication that is agnostic to tissue type or anatomical location.[55] Both larotrectinib and entrectinib have shown response rates between 75% and 80% when used as monotherapy in *NTRK* positive advanced NSCLC patients.

Patients whose tumors harbor an *ROS1* mutation should be treated with crizotinib. Since this mutation is only present in ~1% of tumors it is relatively uncommon and randomized controlled trial data are lacking. Studies have reported 70% to 80% response rates in ROS1 positive patients receiving crizotinib.[56] Other first-line agents include ceritinib and entrectinib, though neither have matched crizotinib's response rate, and lorlatinib is approved for patients with a ROS1 mutation in the second line setting.[15]

For patients with a *MET* mutation, capmatinib and tepotinib are FDA approved targeted therapy. The phase II GEOMETRY trial showed a 71.4% response rate in patients receiving capmatinib with a reported 9 months PFS.[57,58] Additionally, 54% patients with brain metastases who enrolled in GEOMETRY, saw improvement of those brain metastases on study.

Selpercatinib and pralsetinib targeted options for patients with *RET* rearrangements.[59] In a phase I/II trial, first-line therapy with selpercatinib showed an overall response rate of 85%, patients receiving selpercatinib after progressing on chemotherapy showed an almost 70% overall response rate and a median PFS of just over 18 months.[60] Selpercatinib also showed good CNS penetration with 91% of patients who enrolled with brain metastases showing a response to therapy.

For advanced NSCLC patients with no targetable mutations, first-line chemotherapy with a platinum-based doublet is the most commonly used regimen. Patients with stage IIIB or IIIC disease should receive concurrent chemotherapy and radiation, followed by therapy with durvalumab if unresectable disease.[15] Historically, four to six cycles of a platinum-based doublet regimen were used, with an overall response rate of 25% to 35% and 1-year survival rates of 30% to 40%. The PACIFIC trial, which studied the effects of adding maintenance durvalumab to concurrent chemoradiation in patients with stage III unresectable disease, found that durvalumab maintenance therapy had a 2-year overall survival rate of 66%, compared to the placebo maintenance arm at 55%.[61] These data strongly support the use of durvalumab maintenance therapy in advanced, unresectable NSCLC. However, durvalumab therapy is not recommended in patients who have definitive surgical resection. Consolidation chemotherapy (two additional cycles of chemotherapy after concurrent chemoradiation) is an option in patients who are not candidates for consolidation therapy with durvalumab. However, concurrent chemotherapy and durvalumab is not recommended in this setting due to increased risk of pneumonitis. Cisplatin and etoposide are an example of a preferred platinum doublet that can be given with radiotherapy, though many combinations have been studied. Guideline recommended platinum doublets that are considered equivalent and key trials are listed in Table 90–3.

For metastatic patients with nonsquamous NSCLC and no targetable mutational drivers, pembrolizumab with a platinum and pemetrexed chemotherapy doublet is the preferred regimen, regardless of tumor PD-L1 expression, unless there are contraindications to ICI therapy. The addition of pembrolizumab to a platinum and pemetrexed doublet chemotherapy regimen demonstrated a median progression-free survival that was 4 months longer than chemotherapy with placebo, and median overall survival of 22 versus 10.7 months, respectively.[62] If PD-L1 expression is greater than equal to 50% (NCCN category 1) or between 1% and 49% (category 2B), then pembrolizumab monotherapy may be considered. Other acceptable chemoimmunotherapy regimens, irrespective of PD-L1 expression levels, include atezolizumab with carboplatin/paclitaxel/bevacizumab or carboplatin/albumin-bound paclitaxel, or dual immunotherapy with nivolumab (PD-1 inhibitor) and ipilimumab (CTLA-4 inhibitor). In patients with contraindications to ICI therapy, combination chemotherapy with or without bevacizumab are acceptable options. The addition of bevacizumab to carboplatin and paclitaxel improved survival by 2 months (median OS = 12.3 months); however, the survival curve did not plateau at the end, indicating that lung cancer deaths were delayed and not prevented.

Patients who progress after first-line therapy will benefit from second-line therapy. The choice of therapy depends on prior therapies, comorbidities, PS, PD-L1 status, and mutation status. For those not previously treated with immunotherapy, the preferred second-line therapy is a PD1 or PD-L1 inhibitor. Second-line treatment with atezolizumab, nivolumab, or pembrolizumab improved overall survival by 2 to 4 months when compared to docetaxel (the prior standard).[15] If patients received immunotherapy in the first-line setting, their subsequent treatment options include docetaxel, pemetrexed, ramucirumab + docetaxel and gemcitabine. For patients treated with front-line chemoimmunotherapy, second-line treatment with docetaxel would be the standard and adding ramucirumab could be considered. The pivotal study that led to FDA approval of ramucirumab in this setting reported a statistically significant overall survival benefit (10.5 vs 9.1 months); however, the clinical significance of this difference is questionable and this has not become a clear standard of care.

Patients with squamous NSCLC are treated similarly to nonsquamous NSCLC with several notable exceptions. As mentioned earlier, pemetrexed does not provide benefit for this population and should be avoided. Similarly, bevacizumab is not recommended for patients with squamous histologic subtype, due to an increased risk of hemoptysis. Based on secondary endpoints, it appears that a platinum-gemcitabine or platinum-paclitaxel regimen are effective chemotherapy regimens. Immune checkpoint monotherapy, combination chemoimmunotherapy, or dual immunotherapy are treatment options as in nonsquamous NSCLC.[15]

▶ *Special Populations*

Patients who cannot tolerate platinum agents can be treated with gemcitabine-paclitaxel or gemcitabine-docetaxel. Randomized trials have produced response durations and survival times similar to the platinum-containing doublet regimens. However, these regimens are only recommended for patients who are unlikely to tolerate the toxicity of platinum regimens owing to comorbidities or other factors.[15]

Patients with poor PS, defined as those with a PS of 2 or greater, is a subject of debate. Although patients with a PS of 2 typically have inferior survival rates and increased treatment toxicity than higher performing patients, low-toxicity single-agent regimens may offer a survival advantage in this subset. Use of these regimens also presents a method of providing symptomatic care for advanced stage patients. Agents such as pemetrexed, gemcitabine, and docetaxel may be used in this scenario. In patients with a PS of 3 or 4, chemotherapy typically results in high rates of toxicity and without a significant survival benefit. Consequently, treatment should be reserved for cases where it may provide symptomatic relief. Because targeted agents typically have lower rates of severe toxicity, they also have been used in appropriate subsets of patients with a poor PS (ECOG PS of 2 or 3). Unfortunately, there is not adequate clinical trial data regarding the efficacy and toxicity of immunotherapy or targeted agents in these patients. In summary, patients with poor PS should not be treated with combination chemotherapy with or without targeted agents because of historically high rates of toxicity and no evidence of survival benefit. Single-agent therapy is associated with less toxicity and can be used to help palliate symptoms.[15]

▶ *Duration of Therapy*

Because advanced stage lung cancer is not curable, therapeutic goals should include extending the number of quality days, rather than just overall survival. With this in mind and the assumption that quality of life is lower while receiving chemotherapy, it is important to consider the duration of treatment. Over the last decade, treatment has moved toward fewer chemotherapy cycles. Typical cytotoxic doublet therapy regimens have decreased from eight planned cycles to four cycles with the option of two additional cycles if treatment is well tolerated.[15] However, maintenance therapy with a single cytotoxic chemotherapy, targeted therapy, or immunotherapy agent has become the standard.[15]

The duration of therapy for NSCLC also depends on the presence/absence of biomarkers and the agents that are used. For patients without a targetable genetic mutation the duration is determined by the order in which patients received therapies. Patients receiving first-line immunotherapy, with or without chemotherapy, should receive maintenance immunotherapy for 2 years or the development of intolerable side effect. Patients receiving immunotherapy in the second-line or later setting can receive immunotherapy maintenance until progression or the development of intolerable side effects. All of the targeted therapies (oral TKIs) for targetable mutational drivers are continued until disease progression or unacceptable toxicity. At this point, subsequent therapy will be determined based upon the mutation in question, the presence or absence of brain metastasis, and the presence or absence of symptoms and adverse effects. It is possible that patients will continue with the same targeted therapy agent after progression, or may be switched to a different agent within the same class. However, in general, patients will typically remain on a therapy that targets their specific mutation until intolerable side effects. Additionally, any patient with a targetable mutation may switch over to cytotoxic chemotherapy if necessary. However, this is reserved for cases that appear to be refractory to targeted agents and in whom cytotoxic chemotherapy is not contraindicated due to comorbidities or performance status.

In summary, the duration of therapy depends highly on treatment pathway, histology, and initial therapy; cytotoxic chemotherapy rarely exceeds six cycles, while monotherapy and targeted therapies are commonly administered until disease progression except in patients with squamous cell histology, in whom switch maintenance therapy is an option. This involves rotating or switching between monotherapy maintenance options based on patient performance status, history of adverse events, and response to therapy.

Treatment of Small-Cell Lung Cancer

SCLC typically presents as extensive disease (approximately 60%–70% of new cases) and progresses very quickly. SCLC is very responsive to chemotherapy and radiation but has a short

Patient Encounter Part 3

The patient is treated with pembrolizumab 200 mg IV q3 weeks as first-line treatment. Six weeks after starting therapy a repeat CT scan is performed, which shows that the primary 3 cm lesion is now 5 cm in diameter.

Does that mean he has progressed on this treatment?

Discuss how this influences assessment moving forward and propose a treatment and monitoring plan.

duration of response. Radiotherapy became the standard in 1969, when a randomized trial showed that it offered the potential for cure, whereas surgery did not.[63] In the vast majority of patients, chemotherapy, augmented with either radiotherapy or immunotherapy is the treatment of choice. Even after a complete response to therapy, the cancer usually recurs within 6 to 8 months and the survival time following recurrence is short (approximately 4 months). This yields an average survival rate of 24 to 30 months for limited disease and 10 to 13 months for extensive disease.[37]

▶ *Limited Disease*

The regimen of choice for limited-disease SCLC is etoposide with cisplatin. In patients who are able to tolerate combined modality therapy, concomitant chemoradiotherapy offers the greatest survival benefit. Carboplatin may be substituted for cisplatin in patients who cannot tolerate cisplatin toxicity. Cisplatin is associated with significantly more nephrotoxicity and more emetogenicity than carboplatin. Cisplatin is preferred over carboplatin because of a small study that randomized patients to cisplatin or carboplatin plus etoposide. There was a numerically higher complete response rate with cisplatin, which is believed to be requisite for cure. Consequently, the guidelines recommend that the etoposide-platinum regimen be used with concurrent radiotherapy.[37]

Because patients with SCLC commonly have a recurrence in the CNS, trials have been performed to evaluate the benefit of prophylactic cranial irradiation. A pivotal study showed that prophylactic cranial irradiation reduces the incidence of brain metastasis and increases the 3-year survival rate from 15% to 21%.[64] Patients with limited-stage SCLC who achieve a complete response with treatment should be offered prophylactic cranial irradiation.

▶ *Extensive Disease*

In the first-line setting, etoposide-platinum doublet, combined with either atezolizumab or durvalumab is the treatment of choice for extensive disease. Carboplatin is commonly used in place of cisplatin because it is generally thought to have less toxic and demonstrated similar outcomes in progression-free survival and overall survival. The choice of atezolizumab or durvalumab appears to be of little clinical consequence as each showed similar outcomes of 12.3 and 13 months of overall survival, respectively, for first-line treatment of extensive-stage SCLC. At this time there is not thought to be any meaningful difference in the adverse event profile between these two PD-L1 inhibitors and either agent in combination with etoposide-platinum are considered to be preferred regimens.[37] Patients with contraindications to ICI therapy can be treated using these doublet chemotherapy regimens without the PD-L1 inhibitor.

Patient Encounter Part 4

The patient's condition has caused symptoms and periodic interruptions to his tasks, but he has been able to work and complete daily activities up to this point.

What is this patient's ECOG PS score?

Are there any nonpharmacologic interventions you would suggest?

Concurrent radiotherapy is not used routinely in extensive disease; however, prophylactic cranial irradiation provides significant benefit in patients responding to systemic treatment. A pivotal study demonstrated that median survival from the time of randomization increased from 5.4 to 6.7 months and 1-year survival rates increased from 13.3% to 27.1% with prophylactic cranial irradiation.[65] An additional benefit was a lower rate of brain metastases (14.6% vs 40.4%), thought this has not been tested with the addition of immunotherapy to the front-line setting.

▶ *Recurrent Disease*

The treatment of recurrent SCLC depends on the time to recurrence. If the time to recurrence is less than 6 months, nonplatinum based second-line therapy should be considered if the patient has an acceptable PS (0–2) (see Patient Care Process). The most widely accepted second-line therapies in SCLC are topotecan and lurbinectedin, although other acceptable options include nivolumab with or without ipilimumab, pembrolizumab, paclitaxel, docetaxel, irinotecan, oral etoposide, and others. Lurbinectedin is new cytotoxic agent, approved for use in small-cell lung cancer in 2020. This alkylating agent binds to DNA and bends the helix towards the minor groove, disrupting the actions of some transcription and DNA repair pathways.[66] Relapses occurring more than 6 months after treatment warrant a repeat of the initial platinum-based regimen, or lurbinectedin. Patients with a poor PS (3–4) are typically managed with best supportive care, including palliative therapies.[37]

▶ *Duration of Therapy*

For patients with limited stage SCLC, four to six cycles of cytotoxic chemotherapy with radiation is the standard of care. First-line treatment beyond six cycles has not been shown to be beneficial.[37] However, in patients with extensive-stage disease, the standard of care has shifted to four cycles of cytotoxic chemotherapy with an immunotherapy agent, followed by single agent immunotherapy maintenance until disease progression or unacceptable toxicity.[37] Second-line therapy, regardless of stage, is generally continued until progression or intolerable toxicity.

OUTCOME EVALUATION IN LUNG CANCER

Evaluating outcomes is a goal-oriented process and should begin from that perspective. Patients with localized disease are treated with localized therapy with or without systemic therapy, with curative intent as the goal. Monitoring for toxicity and response on a regular basis is essential.

Following surgery or pharmacologic treatment, the patient should be monitored regularly to detect recurrence or progression of disease. Methods include a physical examination and chest X-ray every 3 to 4 months for 2 years. If no disease is detected during this time, follow-up frequency can be prolonged to every 6 months for 3 years and then annually. Low-dose spiral CT scanning is also recommended annually.[15]

For patients who have advanced stage disease, response of target lesions is performed with a radiologic scan every 6 to 12 weeks. Response Evaluation Criteria in Solid Tumors (RECIST)[67] are applied to classify response as follows: complete remission (CR) is complete disappearance of tumor, partial remission (PR) is a reduction in target tumor volume in unilateral diameters by 30% or more, progressive disease (PD) is defined as new lesions or a growth of the target lesion diameter by more than 20%, and stable disease (SD) is defined by not meeting the PR or PD criteria. These criteria have been modified for patients on immunotherapy because the checkpoint inhibitors have a delayed time to antitumor effect due to their mechanisms of action. The process for T-cell activation against tumors, migration to and infiltration of tumor tissue, and then exertion of tumoricidal activity requires more time than the direct cytotoxic and antiproliferative effects typical of traditional chemotherapies. Moreover, immune activation by immunotherapies may transiently increase cellular mass and inflammation-related edema, causing tumors to appear larger on radiologic evaluation prior to observations of antitumor responses. The revised guidelines most commonly used in this scenario is the immune RECIST (iRECIST).[68] The primary difference is that the first progression based on RECIST is considered an immune Unconfirmed Progressive Disease (iUPD). The confirmatory radiology would then occur 4 to 8 weeks later and PD is confirmed if target lesions continue to grow. If they do not grow or shrink to any degree, it would become the new set point and repeat radiologic assessments would reevaluate for iUPD prior to having confirmed PD.[68]

Smoking cessation counseling with or without pharmacologic treatment should be a priority. Although studies have shown that patients who continue to smoke through treatment in NSCLC do not perform more poorly compared with those that quit before treatment, those who respond to treatment and continue to smoke probably have an increased risk of developing secondary malignancies.[69] In contrast to NSCLC, data in SCLC patients suggests increased toxicity in those who continue to smoke during treatment.[37]

For those with advanced disease, the goal of treatment is to prolong the duration of life, particularly the number of quality days. Ultimately, most lung cancer patients succumb to their disease or related complications. Palliative care focuses on the management of symptoms and improvement of quality of life. Symptomatic metastases can be removed by surgery (depending on location) or can be treated with radiotherapy to reduce tumor size. In selecting options in this setting, it is important to keep the goals of therapy (ie, maximizing the duration and quality of life) in mind. Low-toxicity single-agent chemotherapy, targeted therapy, and best supportive care (including fatigue and pain management) may all be employed to attempt to prolong quality days of life in the advanced disease population.

COST-EFFECTIVENESS AND QUALITY OF LIFE CONSIDERATIONS

Cancer treatments such as the molecular and immune targeted therapies currently are much more expensive than traditional chemotherapy. Where there is a clear survival benefit, they should be used over traditional chemotherapy. However, where the efficacy benefit is marginal or minor, cost-effectiveness should be considered because they can pose long-term financial burdens for patients and their families. This is especially the case when immunotherapy is added to another regimen which adds not only significantly more cost but also more toxicities. In cost-effectiveness analyses of pembrolizumab plus chemotherapy versus chemotherapy the incremental cost-effectiveness ratio

Patient Care Process

Collect Information:

- Determine stage and histology of cancer.
- Perform PD-L1 expression and mutation analysis if advanced disease.

Assess the Information:

- Comorbidities and organ and hematological function.
- Starting doses and schedules of planned treatment regimen.
- Need for supportive care therapies.

Develop a Care Plan:

- Ensure the patient has access and insurance coverage for chemotherapy and supportive therapies.
- Educate the patient on expected outcomes, potential adverse effects, and their management.

Implement the Care Plan:

- Evaluate the appropriateness of a patient's regimen at every visit (every week, 3 weeks, or 4 weeks).
- Inquire about toxicity and quality of life issues.
- Include a medication reconciliation process.
- Laboratory and/or radiology evaluations can be prompted by the initial assessment or at a scheduled interval for the treatment regimen.
- Findings of tumor growth or significant toxicity should prompt a change in the therapeutic plan.
- Grade and monitor toxicity—Grade 3 or 4 toxicity (see Chapter 88) requires a change in therapy with the next cycle of treatment. Common changes include a chemotherapy dose reduction or pharmacologic intervention to prevent or treat the toxicity.
- Manage toxicity—*Knowing when and how to treat adverse events from therapy is an important aspect of patient care. Unmanaged events may cause delays in therapy administration and reduced therapy doses and may contribute to treatment failure.* This includes managing neutropenic episodes (see Chapter 99) and chemotherapy-induced nausea and vomiting (see Chapter 99). The emetogenic potential of selected chemotherapy regimens is listed in Chapter 99. For patients on immunotherapy, they must be monitored for immune-related adverse events with early recognition and intervention (see Chapter 88).
- Counsel patients on appropriate use and adherence of oral medications.

Follow-up: Monitor and Evaluate:

- Monitor for recurrence. Follow recommendations of the NCCN, as outlined in Outcome Evaluation.
- Smoking cessation plans. For NSCLC patients, all long-term care plans should include options and recommendations for smoking cessation (see Chapter 36).

(ICER) for the combination regimen was $86,293 to $104,823/quality-adjusted life year (QALY).[70,71] This can be considered cost-effective using either the World Health Organization threshold of $180,000/QALY[71,72] or the traditional USA threshold of $100,000/QALY.[73] The chemo-immunotherapy combination was shown to extend life expectancy in tumors with PD-L1 greater than equal to 50% compared with pembrolizumab monotherapy at an ICER of $147,365/QALY and $118,879/life years, respectively.[70] However, cost-analysis of atezolizumab plus bevacizumab plus chemotherapy versus chemotherapy reported an ICER of $568,967/QALY and $516,114, respectively,[74] suggesting that this may not be cost effective. While additional cost-effectiveness and quality of life studies are needed, these are factors that warrant discussion with the patient when potential efficacy benefits are marginal and treatment toxicities may diminish quality of life.

Abbreviations Introduced in This Chapter

5-FDG	5-Fluorodeoxyglucose
ALK	Anaplastic lymphoma kinase
BRAF	A proto-oncogene kinase that is a sarcoma viral oncogene homolog B
CT	Computed tomography
CTLA-4	Cytotoxic T-Lymphocyte Antigen 4
ECOG	Eastern Cooperative Oncology Group
EGF	Epidermal growth factor
EGFR	Epidermal growth factor receptor
EML4	Echinoderm microtubule-associated protein-like 4
EP	Etoposide-cisplatin
ETS	Environmental tobacco smoke
ICI	Immune Checkpoint Inhibitor
Met	c-Mesenchymal-Epithelial Transition Factor
NSCLC	Non–small cell lung cancer
NTRK	Neurotrophic-tropomyosin receptor kinase or neurotrophic tyrosine receptor kinase
PD1	Programmed cell death protein 1 receptor
PD-L1	Programmed death ligand 1 (aka B7-H1 and CD274)
PET	Positron-emission tomography
PS	Performance status
RET	Rearranged during transfection
RECIST	Response Evaluation Criteria in Solid Tumors
ROS1	ROS Proto-Oncogene 1, Receptor Tyrosine Kinase
SCLC	Small-cell lung cancer
TNM	Tumor, node, and metastasis staging
TRK	Tropomyosin Receptor Kinase
VEGF	Vascular endothelial-derived growth factor

91 Colorectal Cancer

Emily B. Borders and Allison Baxley

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify the risk factors for colorectal cancer.
2. Outline preventive and screening strategies for individuals at average and high risk for colorectal cancer.
3. Recognize the signs and symptoms of colorectal cancer.
4. Describe the treatment options for colorectal cancer based on patient-specific factors, such as stage of disease, age of patient, genetic mutations, and previous treatment received.
5. Outline the pharmacologic principles for agents used to treat colorectal cancer.
6. Develop a monitoring plan to assess the efficacy and toxicity of agents used in colorectal cancer.
7. Educate patients about the adverse effects of chemotherapy that require specific patient counseling.

INTRODUCTION

Colorectal cancer is one of the four most common cancers diagnosed in the United States and includes cancers of the colon and rectum. In 2021, an estimated 149,500 new cases of colorectal cancer are expected to be diagnosed, with an estimated 52,980 deaths expected, making colorectal cancer the second leading cause of cancer-related deaths in the United States.[1] The prognosis is primarily determined by the stage of disease with the majority of patients with early stage (I or II) disease cured. Treatment options for colorectal cancer include surgery, radiation, chemotherapy, and targeted molecular therapies.

EPIDEMIOLOGY AND ETIOLOGY

Colorectal cancer occurs more frequently in industrialized regions such as North America and Europe, while the lowest rates are seen in less-developed areas, suggesting that environmental and dietary factors influence the development of colorectal cancer. In addition to environmental factors, colorectal cancers develop more frequently in certain families, and genetic predisposition to this cancer is well known.

The incidence of colorectal cancer in men is approximately 1.2 times greater than observed in women. Overall, colon and rectal cancers make up approximately 7.9% of all cancer diagnoses in men and women in the United States. The median age at diagnosis is 67 years with few cases occurring in individuals younger than 45 years of age.[2] KEY CONCEPT Age appears to be the biggest risk factor for the development of colorectal cancer with 56% of cases diagnosed in adults older than 65 years of age.

Although still the second leading cause of cancer death, mortality rates for colorectal cancer have declined over the past 30 years as a result of better and increasingly used screening modalities and more effective treatments.

RISK FACTORS

In addition to age, dietary or environmental factors, inflammatory bowel disease, and genetic susceptibility increase the risk of colorectal cancer. Table 91–1 lists well-known risk factors for developing colorectal cancer.

KEY CONCEPT Diets high in fat and low in fiber are associated with increased colorectal cancer risk. While data are not entirely consistent, long-term consumption of red and processed meats is associated with an increased risk of colorectal cancer. A large pooled analysis of 13 prospective cohort studies found dietary fiber intake to be inversely associated with the risk of colorectal cancer; however, upon multivariate analysis for other dietary risk factors, the benefit was no longer observed.[3] This analysis does not consider the known benefits of a fiber-rich diet for noncancerous conditions such as diabetes and coronary artery disease.

Foods that are high in fiber include vegetables, fruit, and grains. The protective effects of fiber may be a result of reduced absorption of carcinogens in the bowel, reduced bowel transit time, or a reduction in dietary fat intake associated with high-fiber diets.[3]

Physical inactivity and elevated body mass index (BMI) are associated with up to a twofold increase in the risk of colorectal cancer. Increasing physical activity, decreased bowel transit time and exercise-induced alterations in body glucose, insulin levels, and other hormones may reduce tumor cell growth.[4,5] Type 2 diabetes mellitus, independent of body mass size and physical activity level, is also associated with an increased risk of colorectal cancer in women and supports a role for hyperinsulinemia as a possible link between obesity, sedentary lifestyle, diabetes mellitus, and colorectal cancer.[5] Additional lifestyle choices that increase the risk of colorectal cancer include alcohol consumption and smoking, which may increase the risk of colorectal cancer by generating carcinogens with direct toxic effects on bowel tissue.[4]

Table 91–1

Risk Factors for Colorectal Cancer

Risk Factors for Colorectal Cancer
General
Age is the primary risk factor
Dietary
High-fat, low-fiber diets
Lifestyle
Alcohol
Smoking
Obesity or physical inactivity
Comorbid Conditions
Inflammatory bowel disease (ulcerative colitis and Crohn disease)
Hereditary or Genetic
FAP and HNPCC
Family history

FAP, familial adenomatous polyposis; HNPCC, hereditary nonpolyposis colorectal cancer.

Patient Encounter Part 1

A 67-year-old man presents to your clinic with a chief complaint of bloating and distention, abdominal discomfort, and intermittent changes in his bowel movements over the past 3 to 4 months. He has a medical history positive for type 2 diabetes mellitus, hyperlipidemia, diabetic neuropathy, and obesity. He states that he quit drinking alcohol almost 30 years ago but is a current smoker (50-pack-year history). He reports he used to eat healthy until his wife passed away almost 10 years ago. Currently his diet mostly consisted of red meats and processed foods. He reports that he hasn't exercised in years.

What risk factors does this patient have for colon cancer?

Does he have clinical symptoms suggestive of colon cancer?

What additional tests need to be ordered to diagnosis colon cancer?

Inflammatory bowel diseases, such as chronic ulcerative colitis, particularly when it involves the entire large intestine, and to lesser extent Crohn disease, confer increased risk for colorectal cancer. Overall, individuals with inflammatory bowel disease account for about 1% to 2% of all new cases of colorectal cancer each year.

Finally, as many as 10% of cases are thought to be hereditary. The two most common forms of hereditary colorectal cancer are familial adenomatous polyposis (FAP) and hereditary nonpolyposis colorectal cancer (HNPCC). FAP is a rare autosomal dominant trait that is caused by mutations of the **adenomatous polyposis coli (*APC*)** gene and accounts for 1% of all colorectal cancers. The disease is manifested by hundreds to thousands of **polyps** arising during adolescence.[6] The risk of developing colorectal cancer for individuals with untreated FAP is nearly 100%, and patients require early screening for the disease and likely a prophylactic total colectomy. HNPCC, also an autosomal dominant syndrome, accounts for up to 5% of colorectal cancer cases.[6] In contrast to FAP, juvenile polyps occur rarely, and the average age of colorectal cancer in these patients is closer to that of average-risk patients, with most patients diagnosed in their 40s. Testing for HNPCC mutations is available but reserved for individuals who meet diagnostic criteria.

Up to 20% of patients who develop colorectal cancer have a family history of colorectal cancer unrelated to a mutation described earlier.[7] First-degree relatives of patients diagnosed with colorectal cancer have an increased risk of the disease that is at least two to four times that of persons in the general population without a family history.

Summary of Risk Factors

In summary, the true association between most dietary factors and the risk of colorectal cancer is unclear. The protective effects of fiber and a diet low in fat are not completely known at this time. Physical inactivity, alcohol use, and smoking appear to increase the risk of colorectal cancer. Certain genetic mutations are well-known risks for colorectal cancer.

SCREENING

KEY CONCEPT Effective colorectal cancer screening programs incorporate annual fecal occult blood testing or regular examination of the entire colon starting at age 45 years for average-risk individuals and should be recommended by all healthcare providers. Appropriate screening of patients at normal and high risk for colorectal cancer leads to the detection of smaller, localized lesions and higher cure rates.[8] Screening techniques include fecal occult blood tests (FOBTs) and imaging of the colon. The use of FOBTs annually in combination with digital rectal examinations has led to the diagnosis of early stages of disease and may reduce colorectal cancer mortality by up to one-third.[8] However, FOBT using a single stool sample collected during a digital rectal examination is not a recommended option for screening because this method has a decreased sensitivity for detecting advanced disease. Recommendations for adequate FOBT require the patient to collect two stool samples from three consecutive specimens using at-home testing procedures.[8] Two main methods are available to detect occult blood in the feces: guaiac dye and immunochemical methods. The Hemoccult II is the most commonly used FOBT in the United States and is a guaiac-based test. Proper counseling by healthcare providers is required to receive accurate test results. Consumption of red meat, blood sausages, peroxidase-containing vegetables, iron products, or nonsteroidal anti-inflammatory drugs (NSAIDs) may result in false-positive results. Vitamin C and dehydrated samples may lead to false-negative results. These products should be avoided for 3 days prior to testing. Fecal immunochemical tests (FITs) (InSure and others), which use antibodies to detect hemoglobin, are also available for use. Though more expensive, an advantage of FITs is that they do not react with dietary factors or medications. Both FOBTs can be recommended in screening protocols for patients.

Imaging of the colon with a sigmoidoscopy, colonoscopy, or CT colonography is recommended every 5 to 10 years for most individuals. Colonoscopy is the preferred procedure as it allows for greater visualization of the entire colon and simultaneous removal of lesions found during screening.[8] A sigmoidoscopy only examines the lower half of the colon. Several revisions to the colorectal cancer screening guidelines have been made in an attempt to increase the compliance to screening guidelines. These include the use of computed tomographic colonography (CTC) and stool DNA testing as acceptable screening methods. CTC, also known as "virtual colonoscopy," uses integrated two- and three-dimensional images to detect and characterize polyps. Although noninvasive compared with colonoscopy, adequate bowel preparation, which is often cited as the reason for noncompliance, is still required. In addition, any lesions found on examination require a follow-up colonoscopy.

Table 91–2

Colon Cancer Screening Guidelines

Average risk	Annual FOBT or FIT after age 45 years Stool DNA testing may be used as an alternative *or* One of the following after age 45 years: Sigmoidoscopy every 5 years Colonoscopy every 10 years CTC every 5 years
Family history	Screening at ages 40 years or 10 years before the youngest case in the immediate family, whichever is earlier
HNPCC	Screening at age 20–25 years or 10 years before the youngest case in the immediate family, whichever is earlier
FAP	Screening at ages 10–12 years
IBD	8 years after the onset of pancolitis; 12–15 years after onset of left-sided colitis

CTC, computed tomographic colonography; FAP, familial adenomatous polyposis; FIT, fecal immunochemical tests; FOBT, fecal occult blood tests; HNPCC, hereditary nonpolyposis colorectal cancer; IBD, inflammatory bowel disease.

Multitarget stool DNA tests with fecal immunochemical testing detect molecular markers (KRAS and methylation biomarkers) as well as FIT for hemoglobin. Advantages of this test are it can be done at home, requires only a single stool collection, and is recommended once every 3 years. However, like virtual CT, positive tests require follow-up colonoscopy. KEY CONCEPT Table 91–2 is a summary of the current NCCN guidelines for screening and surveillance for early detection of colorectal polyps and cancer.[8]

COLORECTAL CANCER PREVENTION

There are currently no pharmacologic agents approved for colorectal cancer prevention. Strategies under investigation to prevent colorectal cancer include pharmacologic and surgical interventions and involve either preventing the initial development of colorectal cancer (primary prevention) or preventing cancer in patients who demonstrate early signs of colorectal cancer (secondary prevention).

The most widely studied agents for the chemoprevention of colorectal cancer are agents that inhibit cyclooxygenase-2 (COX-2) (aspirin, NSAIDs, and selective COX-2 inhibitors) and calcium supplementation.[9] Individual studies have demonstrated that regular (at least two doses per week) NSAID and aspirin use is associated with a 20% to 40% reduction in risk of colorectal cancer in individuals at average risk.[10,11] However, a meta-analysis of over 40 trials suggests the benefit of these agents may be limited to individuals at high risk for developing colorectal cancer.[12] Chronic use of aspirin and other NSAIDs are associated with significant potential adverse effects, including gastrointestinal (GI) and cardiovascular toxicities. These risks limit healthcare professionals from making routine recommendations for use in patients of average risk for colorectal cancer.

The risk of colorectal cancer appears to be inversely related to calcium and folate intake. Calcium supplementation appears to be associated with a moderate reduction in risk of recurrent colorectal adenomas with prospective studies demonstrating a nonstatistical decrease in adenoma recurrence, its role as a chemoprevention agent in the average-risk patient remains under investigation.[9,12]

Exogenous hormone use, particularly postmenopausal hormone replacement therapy, is associated with a significant reduction in colorectal cancer risk in most studies with the greatest benefit in women who are on current hormone replacement therapy.[13] Unfortunately, the known risks of hormone replacement therapy outweigh this benefit, and routine use of hormone replacement therapy to prevent colorectal cancer is not recommended.

Surgical resection remains an option to prevent colorectal cancer in individuals at extremely high risk for its development such as patients diagnosed with FAP. Individuals with FAP who are found to have polyps on screening examinations require total abdominal colectomy. In addition, removal of noncancerous polyps detected during screening colonoscopy is considered the standard of care to prevent the progression of premalignant polyps to cancer.

PATHOPHYSIOLOGY

Anatomy and Bowel Function

The large intestine consists of the cecum; ascending, transverse, descending, and sigmoid colon; and rectum (Figure 91–1).

Four major tissue layers, from the lumen outward, form the large intestine: the mucosa, submucosa, muscularis externa, and serosa. Complete replacement of surface epithelial cells occurs every 7 to 10 days with the total number of epithelial cells remaining constant in normal colonic tissue. As patients age, abnormal cells accumulate on the surface epithelium and protrude into the stream of fecal matter; their contact with fecal mutagens can lead to further cell mutations and eventual adenoma formation.[6]

Colorectal Tumorigenesis

The development of a colorectal neoplasm is a multistep process of several genetic and phenotypic alterations of normal bowel epithelium leading to unregulated cell growth, proliferation, and tumor development. A genetic model has been proposed for colorectal tumorigenesis that describes a process of transformation from adenoma to carcinoma. This model of tumor development reflects an accumulation of mutations within colonic epithelium that gives a selective growth advantage to the cancer cells.[6] Genetic changes include activating mutations of oncogenes,

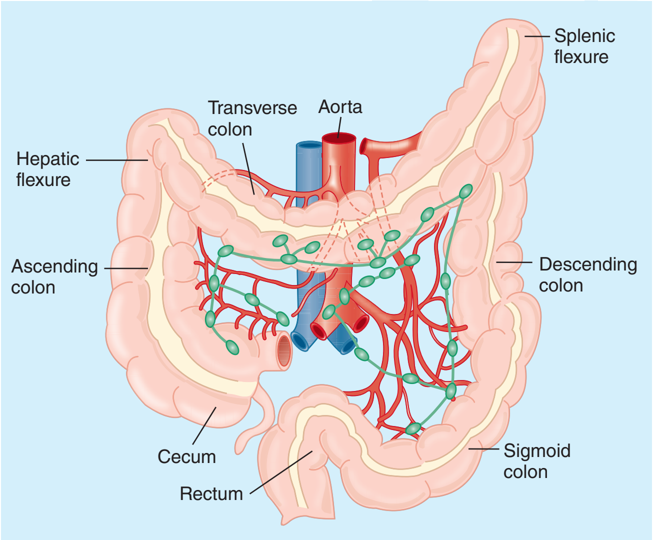

FIGURE 91–1. Colon and rectum anatomy. (From Davis LE, Sun W, Medina PJ. Colorectal Cancer. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill, 2014; Figure 107–2.)

Clinical Presentation and Diagnosis of Colorectal Cancer

General

Patients are often asymptomatic in early stages of disease

Symptoms

Changes in bowel habits, abdominal pain, anorexia, nausea and vomiting, weakness (if anemia is severe), and tenesmus

Signs

Blood in stool and weight loss

Laboratory Tests

- Patients may have a low hemoglobin level from blood loss
- Positive FOBT
- Liver function tests (INR, activated partial thromboplastin time, and bilirubin) may be abnormal if disease has metastasized to the liver.
- CEA level may be high; normal level is less than 2.5 ng/mL (2.5 mcg/L) in nonsmokers and less than 5 ng/mL (5 mcg/L) in smokers.

Imaging Tests

Chest X-ray, CT scan, or PET scan results may be positive if cancer has spread to the lungs, liver, or peritoneal cavity.

mutations of tumor suppressor genes, and defects in DNA mismatch repair genes.

Additional genes and protein receptors are believed important in colorectal tumorigenesis. COX-2, which is induced in colorectal cancer cells, influences apoptosis and other cellular functions in colon cells, and overexpression of EGFR, a transmembrane glycoprotein involved in signaling pathways that affect cell growth, differentiation, proliferation, and angiogenesis, occurs in the majority of colon cancers.[14] These mechanisms are potentially important because of the availability of pharmacologic agents targeted to inhibit these processes.

CLINICAL PRESENTATION AND DIAGNOSIS

The signs and symptoms associated with colorectal cancer can be extremely varied, subtle, and nonspecific. Most patients are asymptomatic but may develop changes in bowel or eating habits, fatigue, abdominal pain, and blood in the stool.

TREATMENT

Desired Outcomes

Patients are staged with the tumor, node, metastasis (TNM) classification system (see Chapter 88) to determine treatment options and assess prognosis. Figure 91–2 depicts how the three categories are used in combination to determine the stage of disease. **KEY CONCEPT** The stage of colorectal cancer upon diagnosis is the most important prognostic factor for survival and disease recurrence. Stages I, II, and III disease are considered potentially curable and are aggressively treated in an attempt to cure these patients. Patients who develop stage IV disease are treated to reduce symptoms, avoid disease-related complications, and prolong survival.

General Approach to Treatment

The treatment approaches for colorectal cancer reflect two primary treatment goals: curative therapy for localized disease (stages I–III) and palliative therapy for metastatic cancer (stage IV). Surgical resection of the primary tumor is the most important part of therapy for patients in whom cure is possible.[16] Depending on the stage of disease and whether the tumor originated in the colon or rectum, further adjuvant chemotherapy or chemotherapy plus radiation may be needed after surgery to cure these patients. In the metastatic setting, pharmacologic intervention is the main treatment option.

Pharmacogenetic and pharmacogenomic testing has become an integral component to designing the optimal pharmacologic intervention for patients with colorectal cancer. The choice of treatment agents is largely dictated by individualized patient and tumor-specific factors. For example, data have demonstrated specific tumor characteristics that may assist clinicians in predicting who will respond to EGFR inhibitors. Early immunohistochemical staining for EGFR status is not useful in predicting response because both EGFR-positive and EGFR-negative patients respond at the same rate. However, *RAS* gene mutation status has demonstrated predictive value. Patients should be tested for both *KRAS*

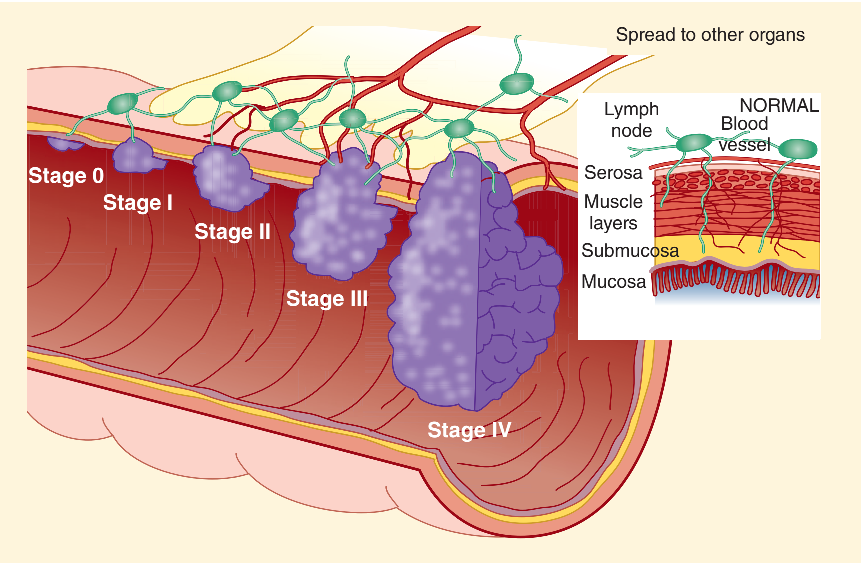

FIGURE 91–2. Stage I: cancer is confined to the lining of the colon. Stage II: cancer may penetrate the wall of the colon into the abdominal cavity but does not invade any local lymph nodes. Stage III: cancer invades one or more lymph nodes but has not spread to distant organs. Stage IV: cancer has spread to distant locations in the body, which may include the liver, lungs, or other sites. (From National Cancer Institute, Washington, DC).

and *NRAS*; patients with mutated *RAS* are unlikely to benefit from cetuximab or panitumumab therapy.[15] In particular, testing for *RAS* mutational status is now part of the disease workup to define patients who may derive benefit from cetuximab or panitumumab. Characteristics of the tumor are also vital in making treatment decisions for patients with stages II and III disease. The degree of microsatellite instability (MSI) within a tumor tells clinicians information about both prognosis and treatment options. More detail on specific pharmacogenetic and pharmacogenomic information is provided in the pertinent pharmacologic therapy sections.

Nonpharmacologic Therapy

▶ *Operable Disease (Stages I–III)*

Surgery Individuals with stages I to III colorectal cancer should undergo a complete surgical resection of the tumor mass with removal of regional lymph nodes as a curative approach for their disease.[16] Surgery for rectal cancer depends on the region of tumor involvement with attempts to retain rectal function as a goal of the surgical procedure. Overall, surgery for colorectal cancer is associated with low morbidity and mortality rates. Common complications include infection, anastomotic leakage, obstruction, adhesion formation, and malabsorption syndromes.

Radiation Therapy There is currently no role for adjuvant radiation in colon cancer. However, patients who receive surgery for rectal cancer receive radiation therapy to reduce local tumor recurrence. Adjuvant radiation plus chemotherapy is considered standard treatment for patients with stage II or III rectal cancer after the surgical procedure is complete.[17] Preoperative chemoradiation using either capecitabine or fluorouracil may be used to reduce the initial size of rectal cancers to make the surgical procedure less extensive.

▶ *Metastatic Disease (Stage IV)*

Surgery Unlike stages I to III disease, the benefit of surgical resection in most patients with metastatic disease is limited to symptomatic improvement. Selected patients who have one to three small nodules isolated to the liver, lungs, or abdomen may have a prolongation of survival, although cure is rare. Five-year survival for patients who undergo surgical resection of metastases isolated to the liver is approximately double than that of patients who are not surgical candidates with approximately 38% of patients alive at 5 years.[18] Alternatives to surgery include destroying the tumor through freezing and thawing (cryoablation), heat (radiofrequency), or alcohol injection, although these appear to be less successful than surgical resection.[15,16,18]

Radiation Symptom reduction is the primary goal of radiation for patients with advanced or metastatic colorectal cancer.

Pharmacologic Therapy

Table 91–3 lists common chemotherapy regimens used in colorectal cancer and the abbreviations used in the literature to describe them.

Table 91–3

Dosing Schedules of Chemotherapy Regimens for Colon Cancer[a]

Regimen	Dosing
5-FU + leucovorin (continuous infusion)	Leucovorin 200 mg/m² IV 5-FU 400 mg/m² IV bolus and then 600 mg/m² of 5-FU as a 22-hour continuous infusion on days 1 and 2; repeat every 2 weeks
FOLFIRI	Irinotecan 180 mg/m² IV day 1 Folinic acid (leucovorin) 400 mg/m² IV day 1 5-FU 400–500 mg/m² IV bolus after folinic acid; then 2400–3000 mg/m² of 5-FU IV over 46 hours Repeat every 14 days
FOLFOX4	Oxaliplatin 85 mg/m² IV + leucovorin 200 mg/m² IV followed by 5-FU 400 mg/m² IV bolus and then 5-FU 600 mg/m² IV over 22 hours day 1 Leucovorin 200 mg/m² IV, followed by 5-FU 400 mg/m² IV bolus and then 5-FU 600 mg/m² IV over 22 hours day 2 Repeat every 2 weeks
mFOLFOX6	Oxaliplatin 85 mg/m² IV day 1 Leucovorin 400 mg/m² IV over 2 hours, followed by 5-FU 400 mg/m² IV bolus day 1 followed by 2400 mg/m² IV over 48 hours Repeat every 2 weeks
FOLFOXIRI	Irinotecan 165 mg/m² IV day 1 Oxaliplatin 85 mg/m² IV day 1 Leucovorin 200 mg/m² IV over 2 hours, followed by 5-FU 3200 mg/m² IV over 48 hours Repeat every 2 weeks
Bevacizumab + 5-FU regimen	Bevacizumab 5 mg/kg IV every 2 weeks + a 5-FU–containing regimen (FOLFOX, FOLFIRI, or 5-FU + leucovorin) Bevacizumab 7.5 mg/kg IV every 3 weeks with CapeOX
Cetuximab ± irinotecan	Cetuximab 400 mg/m² IV first infusion, then 250 mg/m² weekly ± irinotecan 125 mg/m² IV every week for 4 weeks Repeat irinotecan every 6 weeks (after a 2-week break)
Panitumumab	6 mg/kg IV every 2 weeks
Capecitabine	1250 mg/m² twice a day orally for 14 days Repeat every 3 weeks
CapeOX	Capecitabine 1000 mg/m² twice a day orally for 14 days Oxaliplatin 130 mg/m² IV on day 1 Repeat every 3 weeks

[a] Note that many variations exist, and current literature should be checked before administering any chemotherapy regimen.

5-FU, 5-fluorouracil; IV, intravenous.

Patient Encounter Part 2

PMH: Type 2 diabetes mellitus since 60 years, hyperlipidemia since 40 years, diabetic neuropathy since 65 years, obesity; the patient is 40% over his ideal body weight.

FH: Father died at age 74 years of lung cancer; mother died at age 81 of congestive heart failure; older sister with breast cancer; maternal uncle died at age 53 years from rectal cancer.

SH: Retired from the sales industry. Widowed with three grown children. Volunteers at local organization delivering meals.

Meds: Metformin 1000 mg po daily BID, liraglutide 1.2 SUBQ daily; gabapentin 300 mg po TID, pravastatin 40 mg daily.

ROS: (+) Abdominal cramping, diarrhea, constipation, and fatigue.

PE:

VS: 146/94 mm Hg, P 74 beats/min, RR 18 breaths/min, T 37.1°C (98.8°F), Ht 187 cm (74 in.), Wt 115 kg (253 lb).

Abd: Distended and tender to touch, (+) bowel sounds.

Labs: Positive hemoglobin 12.0 g/dL (120 g/L or 7.45 mmol/L) decreased from 13.9 g/dL (139 g/L or 8.63 mmol/L) last year. Positive lipid panel: triglycerides 279 mg/dL (3.15 mmol/L). Hemoglobin A1C 6.9% (goal:<7%)

Imaging and Diagnostic Studies

- Colonoscopy revealed multiple polyps in his transverse colon.
- Biopsy revealed two polyps positive for adenocarcinoma of the colon.
- T4 lesion present with disease spreading through the bowel wall.
- Staging CT scan negative for disease outside of the colon.
- Biopsied lymph nodes were negative for disease.
- Tumors positive for low levels of microsatellite instability.

Because the patient has stage II colon cancer, how does this affect the goal of your treatment plan compared with stage IV disease?

What nonpharmacologic and pharmacologic options are available to this patient?

▶ *Operable Disease (Stages I–III)*

KEY CONCEPT Adjuvant chemotherapy is administered after tumor resection to decrease relapse rates and improve survival in patients with colon cancer by eliminating micrometastatic disease that is undetected on imaging studies. Patients diagnosed with stage I colon or rectal cancer are usually cured by surgical resection, and adjuvant chemotherapy is not indicated in these patients.[16] The role of adjuvant chemotherapy for stage II colon cancer is controversial but may benefit certain high-risk groups. Adjuvant chemotherapy is standard therapy for patients with stage III colon cancer. Table 91–4 lists adjuvant treatment regimens based on stage and performance status (PS). Adjuvant chemotherapy for patients with stage II disease has not been shown to be superior to surgery alone with the possible exception of high-risk patients, including those with inadequate nodes sampled for staging, bowel perforation upon diagnosis, T4 lesions, and those with unfavorable histology.[15] The risks and benefits of adjuvant chemotherapy should be discussed with medically fit patients who have stage II disease with high-risk features. However, the American Society of Clinical Oncology does not recommend the routine use of adjuvant chemotherapy in the general patient population with stage II disease unless part of a clinical trial.[19]

Table 91–4

Adjuvant Treatment Regimens for Colon Cancer

Stage II[a]	Stage III
High Risk	**Good Performance Status**
• Capecitabine or 5-FU plus leucovorin	• FOLFOX
• FOLFOX	• CapeOX
• CapeOx	• FLOX
• FLOX	• Capecitabine or 5-FU plus leucovorin
Low Risk[b]	**Poor Performance Status**
• Observation or clinical trial	• Capecitabine
• Capecitabine or 5-FU plus leucovorin	

[a] Individualized assessment of patient risk is necessary to determine if treatment is required. Clinical trials or observation may be an appropriate option.

[b] T3 lesions may be considered high risk by some clinicians.

5-FU, 5-fluorouracil.

There are currently insufficient data to recommend the use of tumor gene profiling to determine the need for adjuvant therapy in stage II disease, but it is an area of active research.[15] An additional consideration for deciding on adjuvant therapy is the status of MSI within the tumor. MSI results from defective DNA mismatch repair (dMMR) genes leading to damaged DNA. Patients with tumors that display high levels of MSI may have better prognosis than patients with microsatellite-stable (MSS) tumors. Despite being associated with a better prognosis, tumors that display high levels of MSI (MSI-H) do not respond as well to certain chemotherapy, including 5-fluorouracil (5-FU).[20] It is recommended that stage II patients should be tested for the status of MSI if 5-FU is being considered for therapy, and an alternative therapy should be considered if high levels of MSI are displayed.[15] In general, patients with stage II colon cancer should be enrolled into clinical trials to assess the impact of new agents and prognostic models.

Adjuvant chemotherapy is standard therapy for patients with stage III colon cancer. The presence of lymph node involvement in the resected specimen places patients with stage III colon cancer at high risk for relapse; the risk of death within 5 years of surgical resection alone is as high as 70%.[16] In this population of patients, adjuvant chemotherapy significantly decreases the risk of cancer recurrence and death and is considered standard of care.

KEY CONCEPT 5-FU, leucovorin, and oxaliplatin (FOLFOX)-based chemotherapy is the standard regimen used in adjuvant colon cancer. It is usually given for 6 months. Refer to Tables 91–3 and 91–4 for recommended treatment regimens and schedules. 5-FU alone results in a small improvement in survival that can vary based on the method of 5-FU administration and the status of MSI.[20]

The combination of 5-FU plus leucovorin has undergone extensive study in the adjuvant setting with decreased rates of recurrence and improved survival seen in patients receiving 5-FU plus leucovorin compared with surgery alone. Though various schedules of 5-FU and leucovorin can be administered, continuous infusions may be less toxic and have improved response rates (although no survival advantage) compared with bolus regimens. Capecitabine is an oral prodrug of 5-FU that is also effective in the adjuvant setting and is being used as a replacement in certain regimens for 5-FU. Data suggest that capecitabine is at least equivalent to bolus 5-FU and leucovorin in efficacy and is better tolerated by patients in the adjuvant setting.[21] An increase in hand–foot syndrome and decreased mucositis and neutropenia are seen with capecitabine compared with bolus 5-FU.

More often, 5-FU or capecitabine is administered as part of a combination regimen with oxaliplatin and leucovorin (FOLFOX or CapeOx). FOLFOX is considered standard of care for patients with stage III disease unless their PS is so poor that clinicians do not believe the patients could tolerate intensive combination therapy. Every effort should be made to minimize adverse treatment effects and use this regimen in patients with stage III colon cancer because this is the only regimen demonstrated to improve overall survival.[16,22] Several variations on the original FOLFOX regimen have been studied with mFOLFOX6 being the most routinely used in clinical practice (refer to Table 91–4). CapeOx resulted in improved disease-free survival (DFS) compared with bolus 5-FU-leucovorin, but no overall survival benefit in stage III patients and is considered an acceptable adjuvant regimen in this patient population.[15,23]

Targeted therapies, including cetuximab and bevacizumab, have been evaluated for their role in their adjuvant treatment of colon cancer. At this time, no targeted agents are approved for use as adjuvant therapy in stage II or III colorectal cancer patients. Additionally, irinotecan should not be used in the adjuvant setting because its addition to 5-FU–based regimens has increased toxicity without therapeutic benefit.[15]

▶ *Metastatic Disease (Stage IV)*

Traditional chemotherapy and targeted biological therapies are the mainstay of treatment for metastatic colon or rectal cancer and have improved the median survival time of these patients to more than 2 years.[16] Most often, a combination of chemotherapy agents with biological therapies is administered to these patients. Currently, metastatic colorectal cancer is incurable, and treatment goals are to reduce patients' symptoms, improve quality of life, and extend survival. Combination chemotherapy regimens have been demonstrated to result in prolongation of survival with tolerable adverse effects. Similar to the adjuvant setting, 5-FU plus leucovorin continues to be in most first-line chemotherapy regimens used for metastatic colorectal cancer. A variety of continuous intravenous (IV) infusion 5-FU and bolus regimens can be used; however, compared with IV bolus 5-FU, response rates with the continuous infusion 5-FU are approximately doubled. In a large meta-analysis of patients with advanced colorectal cancer, continuous infusions of 5-FU had a significantly higher tumor response rate, a small increase in survival, and lower incidence of myelosuppression, diarrhea, and mucositis when compared with bolus regimens.[24]

Additional agents including irinotecan and oxaliplatin have been added to 5-FU and leucovorin regimens with superior response and survival rates compared to the two drugs used alone.[25,26] A large European study compared a combined bolus and infusional 5-FU regimen plus irinotecan (FOLFIRI) with the FOLFOX regimen (using a slightly different schedule) with crossover to the opposite arm upon relapse.[27] No difference in patient survival was seen with either regimen, and toxicity was as expected. Neuropathy and neutropenia were more common with FOLFOX, while diarrhea, nausea, vomiting, dehydration, and febrile neutropenia were more common with FOLFIRI. Based on improved survival data with the FOLFOX and FOLFIRI regimens, irinotecan-based regimens should be administered outlined as described in Table 91–3.

Capecitabine also has activity in the metastatic setting. When combined with oxaliplatin in regimens known as CapeOx or XELOX, capecitabine appears to be as safe as 5-FU–based regimens.[15] Additionally, progression-free survival (PFS) with CapeOX is similar to that of FOLFOX and is considered noninferior to the FOLFOX regimen as first-line therapy in advanced disease.[28] This noninferiority with capecitabine may be specific to its use with oxaliplatin because capecitabine in combination with irinotecan (CAPIRI) demonstrated decreased PFS compared with FOLFIRI and the routine substitution of 5-FU with capecitabine in irinotecan-based regimens is not recommended.[15,29]

5-FU plus leucovorin, or capecitabine alone, are appropriate first-line treatment options for individuals for whom three-drug combination regimens are believed to be toxic. The site(s) of tumor involvement, history of prior chemotherapy, and patient-specific factors help define the appropriate management strategy. **KEY CONCEPT** The most important factor in patient survival is not the initial regimen but whether or not patients receive all three active chemotherapy drugs (5-FU, irinotecan, and oxaliplatin) at some point in their treatment course.[30] Some clinicians choose to use all three agents in combination in the first-line setting in a regimen termed FOLFOXIRI, although only in patients who are able to tolerate intensive therapy.

Targeted or biologic agents are approved for use in metastatic colorectal cancer. Bevacizumab in combination with IV 5-FU–based chemotherapy (either FOLFOX or FOLFIRI) is approved by the FDA for initial treatment of patients with metastatic colorectal cancer. Results from randomized trials show increased benefit compared with chemotherapy alone.[15] The efficacy of bevacizumab in this patient population shows the relevance of angiogenesis as an important target for the treatment of metastatic colorectal cancer. The addition of bevacizumab to first-line oxaliplatin-based chemotherapy has also been demonstrated to improve PFS but did not positively impact response rates or overall survival.[31] Similar results were demonstrated with bevacizumab in combination with capecitabine and oxaliplatin.[42]

Based on these results, bevacizumab is recommended as part of 5-FU–based chemotherapy regimens used for the first-line treatment of metastatic colorectal cancer unless contraindicated. Bevacizumab is contraindicated in patients with GI perforation or fistulas involving a major organ, recent (within 28 days) major surgeries or open wounds, wound dehiscence requiring medical intervention, hypertensive crisis or uncontrolled severe hypertension, hypertensive encephalopathy—serious bleeding, a severe arterial thromboembolic event, moderate or severe proteinuria (urine protein excretion 2 g/24 hours or more), nephrotic syndrome, and reversible posterior leukoencephalopathy syndrome.

Monoclonal antibody EGFR inhibitors, cetuximab and panitumumab, demonstrate improved PFS as first-line therapy in the metastatic setting when individually combined with either the FOLFOX or FOLFIRI regimens in *RAS* wild-type individuals.[32-35] In addition, pembrolizumab may be considered in patients with MSI-H cancers and encorafenib with cetuximab or panitumumab for those with a BRAF V600E mutation. **KEY CONCEPT** Before using these agents, testing for *RAS* (*KRAS* and *NRAS*), *BRAF* and *MSI-H* mutation status should occur. Extensive literature exists, demonstrating poor response rates of EGFR inhibitors in patients whose tumors have a mutation in exons 2, 3, or 4 of the *KRAS* or *NRAS* genes.[15,36] Consequently, cetuximab or panitumumab may be used in the first-line setting in combination with traditional chemotherapy agents in *RAS* WT patients only.[15]

Attempts to combine the vascular endothelial growth factor (VEGF) inhibitor bevacizumab with cetuximab and panitumumab as part of traditional chemotherapy regimens have resulted in inferior outcomes to regimens with bevacizumab alone.[37] Based on these results, the use of bevacizumab with either EGFR inhibitor is not recommended.[15]

KEY CONCEPT In summary, most practitioners select first-line treatment for metastatic colorectal cancer from among these treatments: oxaliplatin plus 5-FU plus leucovorin (FOLFOX); irinotecan plus 5-FU plus leucovorin (FOLFIRI); capecitabine plus oxaliplatin (CapeOx or XELOX); oxaliplatin plus irinotecan plus 5-FU plus leucovorin (FOLFOXIRI); bevacizumab plus 5-FU- or capecitabine-based chemotherapy (FOLFIRI or FOLFOX or CapeOx or FOLFOXIRI); or cetuximab or panitumumab plus 5-FU–based chemotherapy (FOLFOX or FOLFIRI) in *RAS* WT patients.[15]

▶ *Second-Line Therapy*

KEY CONCEPT Treatment of relapsed or refractory metastatic disease uses agents not given in the first-line setting. Patients who receive all effective chemotherapy options have improved outcomes compared with those who do not. Because most patients will have received a combination of 5-FU or capecitabine with either irinotecan or oxaliplatin, second-line therapy with the alternate regimen should be considered.[15] For example, a patient who received FOLFOX plus bevacizumab as first-line therapy for metastatic disease should be offered FOLFIRI as part of their second-line regimen. EGFR inhibitors are an additional option for use in the second-line setting in patients with WT *RAS* only. Patients who did not have an EGFR inhibitor in their first-line regimens are candidates for single-agent cetuximab or panitumumab or either agent in combination with 5-FU and irinotecan (FOLFIRI + EGFR inhibitor). Additionally cetuximab plus irinotecan can be used without the inclusion of 5-FU. The use of EGFR inhibitors may be beneficial as monotherapy, but response rates and PFS appear to be increased in combination with irinotecan-based chemotherapy.[38-42] The results appear to be best when irinotecan is continued because of synergy demonstrated between the two classes of agents.[15,38]

If targeted agents such as bevacizumab were not part of the initial regimen, addition to the second-line regimen should be strongly considered. The addition of bevacizumab to FOLFOX has been shown to increase overall survival.[43] Bevacizumab as monotherapy was shown to be inferior to FOLFOX4 in efficacy and should not be considered a treatment option in the second-line setting. In patients receiving bevacizumab as part of first-line therapy, continuation of bevacizumab with second-line therapy is associated with increased survival.[44] Based on these findings, continuation of bevacizumab in combination with traditional second-line chemotherapy regimens (5-FU-irinotecan- or 5-FU-oxaliplatin–based) can be considered in patients treated with a first-line bevacizumab-containing regimen. Additional agents targeting VEGF, ziv-aflibercept or ramucirumab, in combination with FOLFIRI can also be considered for use in the second-line setting in patients who have progressed following an oxaliplatin-based first-line regimen. A modest increase in overall and PFS was found in patients receiving FOLFIRI plus ziv-aflibercept compared to FOLFIRI alone.[45] In two separate clinical trials, the addition of ramucirumab or ziv-aflibercept to FOLFIRI led to a modest increase in overall and PFS when compared to FOLFIRI alone.[45,46] Adverse events and warnings for use with ziv-aflibercept or ramucirumab are similar to those with bevacizumab and described in the section of specific agents. Table 91–5 lists treatment options for first- and second-line treatment of metastatic colorectal cancer. Patients with good PS are treated more aggressively than those with poor PS because of their ability to better tolerate chemotherapy.

Table 91–5

Treatment Options for Metastatic Colon Cancer[a]

First-Line Therapy	Second-Line Therapy
Good Performance Status	**If First-Line Irinotecan**
• FOLFOX or FOLFIRI with bevacizumab • FOLFOX or FOLFIRI with cetuximab or panitumumab[c] • FOLFOXIRI with or without bevacizumab • 5-FU + leucovorin or capecitabine with or without bevacizumab	• FOLFOX with or without bevacizumab[b] • Irinotecan with or without cetuximab[c,d] • Capecitabine or 5-FU plus leucovorin
Poor Performance Status	**If First-Line Oxaliplatin**
• Capecitabine or 5-FU plus leucovorin with or without bevacizumab	• FOLFIRI with or without bevacizumab • FOLFIRI with ziv-aflibercept • Irinotecan with ziv-aflibercept • FOLFIRI or irinotecan with or without cetuximab or panitumumab[c,d]

[a]CapeOX may replace FOLFOX in selected patients.

[b]Bevacizumab may be given if not part of the first-line therapy.

[c]If *RAS* wild type.

[d]Cetuximab or panitumumab may be given if not part of first-line therapy.

5-FU, 5-fluorouracil.

▶ *Salvage Therapy*

Several salvage therapy options exist for patients with colorectal cancer who have progressed beyond standard first- and second-line therapy. Panitumumab is approved for patients who have progressed after 5-FU, oxaliplatin, and irinotecan. Compared with best supportive care, it improves time to disease progression.[15] Based on improvement in PFS compared to best supportive care, the multiple tyrosine kinase inhibitor, regorafenib, was approved as a single agent for metastatic colorectal cancer in the third- or fourth-line setting.[47] Trifluridine and tipiracil is another oral treatment option for patients who have been previously treated with all standard therapies. This agent gained FDA approval after demonstrating improved overall survival when compared with placebo.[48]

An additional option in patients with metastatic colorectal cancer and who also demonstrate high MSI or dMMR disease is pembrolizumab. Patients with these particular tumor characteristics have demonstrated notable clinical benefit in early clinical trial data, thus prompting FDA approval in this setting.[49] Although several salvage options exist, patients who fail standard treatment for metastatic colorectal cancer should be encouraged to participate in a clinical trial evaluating new treatment approaches for this incurable disease.

Patient Encounter Part 3

Based on the information presented, create a care plan for this patient's colon cancer. Your plan should include:

(a) The patient's drug- and nondrug-related needs and problems.

(b) The goals of therapy.

(c) A treatment plan specific to this patient that includes strategies to prevent adverse effects of chemotherapy.

(d) A follow-up plan to determine whether the goals have been achieved and the adverse effects of chemotherapy have been minimized.

SPECIFIC AGENTS USED IN COLORECTAL CANCER

Table 91–6 lists FDA-approved drugs used in colorectal cancer along with their mechanisms of action, common toxicities, and recommended dose adjustments for hepatic and renal dysfunction as well as pharmacogenetic considerations.

5-Fluorouracil

5-Fluorouracil (5-FU) acts as a "false" pyrimidine inhibiting the formation of the DNA base thymidine as described in Chapter 88.[16]

5-FU is commonly used in the adjuvant and metastatic treatment of colon and rectal cancers with common regimens listed in Table 91–3. Clinical studies comparing efficacy of bolus and continuous infusion schedules generally favor continuous infusion of 5-FU. This is consistent with evidence that suggests that the duration of infusion may be an important determinant of the biologic activity of 5-FU, particularly because of its short plasma half-life, S-phase specificity, and relatively slow growth of colon tumors.[16,50]

Clinically significant differences in toxicity also differ based on the dose, route, and schedule of 5-FU administration. Leukopenia and mucositis are the primary dose-limiting toxicities of bolus 5-FU, whereas palmar–plantar erythrodysesthesia ("hand–foot syndrome") and diarrhea occur most frequently with continuous infusions of 5-FU.[16,50] Healthcare practitioners can offer valuable patient advice to decrease the impact of these adverse effects. Patients can be informed to suck on ice chips before and for up to 30 minutes after 5-FU boluses to decrease the incidence of mucositis. Hand–foot syndrome, characterized by painful swelling and redness of the soles of the feet and palms of the hand, can be minimized with loose-fitting clothing and keeping skin moist. Additional toxicities include moderate nausea and vomiting, skin discoloration, nail changes, photosensitivity, and neurologic toxicity.

An additional determinate of 5-FU toxicity, regardless of the method of administration, is related to its catabolism and pharmacogenomic factors. Dihydropyrimidine dehydrogenase (DPD) is the main enzyme responsible for the catabolism of 5-FU to inactive metabolites.[48] A number of polymorphisms in DPD have been identified in which patients have a complete or near-complete deficiency of this enzyme. This results in unusually severe toxicity, including death, after the administration of 5-FU. Approximately 3% of patients have a complete lack of DPD activity with other patients demonstrating a partial deficiency in enzyme activity. Although patients may be tested for level of DPD activity, it is not routinely done but may be considered in patients who develop severe toxicity after 5-FU administration. The response to 5-FU is also influenced by the status of MSI within the tumor. Tumors with high levels of MSI are generally more resistant to 5-FU despite being associated with better prognosis.

Leucovorin is commonly given with 5-FU. Leucovorin acts to increase the affinity of 5-FU to thymidine synthase, thus increasing the pharmacologic activity of 5-FU.[16] Leucovorin is most effective when administered before 5-FU and can be given by IV bolus or as a continuous infusion. 5-FU toxicities (leukopenia, mucositis, and diarrhea) are increased when leucovorin is given in combination with 5-FU.

Capecitabine

Capecitabine (Xeloda) is an oral prodrug of 5-FU that is designed to be selectively activated by tumor cells. Capecitabine undergoes a three-step conversion to 5-FU, the last step being phosphorylation by thymidine phosphorylase (TP). TP levels are reported to be higher in tumor cells than normal tissues; therefore, the systemic exposure of active drug is minimized, and tumor concentrations of the active drugs are optimized.[16,22] After the drug is converted to 5-FU, it has the same mechanism of action. The current FDA-approved indication for capecitabine is for use in metastatic and adjuvant colorectal cancer when monotherapy is desired, although it is actively being investigated as a replacement for 5-FU in most combinations of colon and rectal cancer regimens. Hand–foot syndrome and diarrhea are common with capecitabine because its toxicities (and pharmacologic activity) appear to mimic those of continuous infusions of 5-FU.

The dose of capecitabine ranges from 1000 to 1250 mg/m^2 twice a day when used alone; lower doses are often used when it is given in combination with irinotecan or oxaliplatin or in patients with renal insufficiency. The dose should be taken on a full stomach with breakfast and dinner. Capecitabine administered with warfarin can result in significant increases in patients' international normalized ratio (INR) and requires close monitoring. The convenience of oral administration, potentially requiring fewer clinic visits, and an improvement in toxicity make capecitabine a useful alternative to IV 5-FU both by itself and incorporated into other regimens used in colorectal cancer.

Irinotecan

Irinotecan (Camptosar) is a topoisomerase-I inhibitor that forms a complex with the covalently bound DNA topoisomerase I enzyme and interferes with the DNA breakage–resealing process. Binding permits uncoiling of the double-stranded DNA, but it prevents subsequent resealing of the DNA, resulting in double-stranded DNA breaks. Irinotecan is a prodrug that is converted by carboxylesterases to its active form, SN-38. Irinotecan is indicated for the first-line treatment of metastatic colorectal cancer in combination with 5-FU and leucovorin or as a single agent in patients who fail first-line therapies. Irinotecan is not recommended as part of the adjuvant treatment of colorectal cancer at this time.

The major toxicity of irinotecan is diarrhea, which can occur both early and late in therapy.[15,50] The early diarrhea is a cholinergic reaction that occurs in the first 24 hours (often during the infusion) in up to 10% of patients and responds to atropine 0.25 to 1 mg IV. The late diarrhea seen in a larger percent of patients occurs 7 to 14 days after the irinotecan infusion. Healthcare practitioners have to be diligent in counseling patients on this adverse reaction and counseling them on the proper use of antidiarrheals. At the first change in bowel habits, an intensive loperamide regimen should be started by patients (4 mg initially followed by 2 mg every 2 hours until diarrhea free for 12 hours). If diarrhea does not stop or if it worsens, patients should be instructed to

Table 91–6

FDA-Approved Drugs Used in Colon Cancer

Generic Name (Trade Name)	Mechanism of Action	Common Toxicities	Dosing Adjustments for Renal or Hepatic Dysfunction or Pharmacogenetic Considerations
5-FU	Inhibition of the enzyme thymidylate synthase, the rate-limiting step in thymidine formation	*Dose limiting:* Myelosuppression and mucositis with bolus administration Diarrhea and hand–foot syndrome with continuous infusion *Additional toxicities:* Skin discoloration, nail changes, photosensitivity, and neurologic toxicity	Do not give if bilirubin greater than 5 mg/dL (86 µmol/L) DPD deficiency may result in increased toxicity. Testing not routine but may be considered in those with excessive toxicity
Capecitabine (Xeloda)	Orally active prodrug of 5-FU. Once activated, the mechanism of action is the same	Similar to continuous infusion 5-FU	CrCl 30–50 mL/min (0.50–0.83 mL/s) decrease starting dose to 75% of the original dose Do not give if CrCl< 30 mL/min (0.50 mL/s)
Irinotecan (Camptosar)	Topoisomerase inhibitor that forms a complex with the covalently bound DNA topoisomerase enzyme and interferes with the DNA breakage–resealing process	*Dose limiting:* Early and late diarrhea *Additional toxicities:* Neutropenia, nausea, and vomiting	Decrease dose one level in patients with a homozygous UGT1A1*28 allele. Having this allele decreases the hepatic metabolism of irinotecan and increases the toxicity
Oxaliplatin (Eloxatin)	Similar to other platinum analogues (cisplatin) in that it binds to the N-7 position of guanine, which results in cross-linking of DNA and double-stranded DNA breaks	*Dose limiting:* Acute (within first 2 days) and persistent (> 14 days) neuropathies *Additional toxicities:* Anaphylactic-like reactions, dyspnea, nausea, vomiting	No formal dose adjustment, though use with caution in patients with mild-to-moderate renal dysfunction
Bevacizumab (Avastin)	Monoclonal antibody that binds to VEGF and inhibits angiogenesis	*Dose limiting:* Hypertension, bleeding episodes, thrombotic events *Additional toxicities:* Rare perforation of the bowel, proteinuria	None
Ziv-aflibercept (Zaltrap)	Recombinant fusion protein that binds to VEGF and inhibits angiogenesis	*Dose limiting:* Hypertension, bleeding episodes, thrombotic events, infection, diarrhea *Additional toxicities:* Rare perforation of the bowel, proteinuria	None
Ramucirumab (Cyramza)	Monoclonal antibody that binds to VEGF-2 and inhibits angiogenesis	*Dose limiting:* Hypertension, bleeding, thrombosis *Additional toxicities:* Gastrointestinal perforation, proteinuria, delayed wound healing	None
Regorafenib (Stivarga)	Multiple protein kinase inhibitor, including VEGF KIT, PDGFR, RET, FGFR, TIE2, DDR2, TrkA, Eph2A, RAF-1, BRAF, SAPK2, PTK5, and Abl	*Dose limiting:* Hypertension, hand–foot skin reaction *Additional toxicities:* GI perforation, impaired wound healing, hemorrhage, RPLS, fatigue, electrolyte imbalance, hepatotoxicity	Do not use if Child-Pugh class C hepatic impairment Specific recommendations exist for hepatotoxicity developing while on therapy
Cetuximab (Erbitux)	Binds to the cell surface EGFR, preventing EGF and TGF-α binding. This decreased cell proliferation of cancer cells	*Dose limiting:* Infusion-related reactions, acneiform skin rash *Additional toxicities:* Diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease	*KRAS* WT only
Panitumumab (Vectibix)	Similar to cetuximab	*Dose limiting:* Acneiform skin rash *Additional toxicities:* Infusion-related reactions, diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease	*KRAS* WT only

(Continued)

Table 91–6

FDA-Approved Drugs Used in Colon Cancer (*Continued*)

Generic Name (Trade Name)	Mechanism of Action	Common Toxicities	Dosing Adjustments for Renal or Hepatic Dysfunction or Pharmacogenetic Considerations
Trifluridine/ tipiracil (Lonsurf)	Thymidine analog, inhibits DNA synthesis	*Dose limiting:* Myelosuppression *Additional toxicities:* Nausea, diarrhea, stomatitis	Do not initiate therapy in moderate or severe hepatic impairment
Pembrolizumab (Keytruda)	Monoclonal antibody that inhibits PD-1 receptor and prevents PD-1 pathway activation	*Toxicities:* Immune-mediated colitis, dermatitis, hepatitis, etc	Indicated for MSI-H

5-FU, 5-fluorouracil; CrCl, creatinine clearance; EGF, epidermal growth factor; EGFR, epidermal growth factor receptor; PD, programmed death; RPLS, reversible posterior leukoencephalopathy syndrome; TGF, transforming growth factor; VEGF, vascular endothelial growth factor; WT, wild type.

call their healthcare provider immediately. Late-onset diarrhea may require hospitalization or discontinuation of therapy, and fatalities have been reported. Additional toxicities with irinotecan include leukopenia (including neutropenic fever) and moderate nausea and vomiting. Toxicities of irinotecan appear to be greater when the drug is given weekly compared with other administration schedules.

Similar to 5-FU, a pharmacogenomic abnormality is associated with irinotecan toxicity. UDP-glucuronosyltransferase (UGT1A1) is an enzyme that is responsible for the glucuronidation of SN-38 to inactive metabolites, and reduced or deficient levels of this enzyme correlate with irinotecan-induced diarrhea and neutropenia.[15,50] The FDA approved a blood test that detects variations in this gene. This test may assist healthcare providers in predicting which patients may develop severe toxicities from "normal" doses of irinotecan and can be ordered before patients receive irinotecan.[15] The package insert recommends dose reductions of one level in patients who are UGT1A1 homozygous variants. Irinotecan is administered as an IV bolus over 60 to 90 minutes in a variety of dosing schedules.

Oxaliplatin

Oxaliplatin (Eloxatin) is similar to other platinum analogues (cisplatin) in that it binds to the N-7 position of guanine that results in cross-linking of DNA and double-stranded DNA breaks.[50] Oxaliplatin differs from cisplatin in that the DNA damage induced by oxaliplatin may not be as easily recognized by DNA repair genes often seen in colorectal cancer. Oxaliplatin, in combination with 5-FU–based regimens, is indicated for the first- and second-line treatment of metastatic colorectal cancer as well as the adjuvant treatment of colorectal cancer.

The dose-limiting toxicity of oxaliplatin is acute and chronic neuropathy.[16] Acute neuropathies occur within 1 to 2 days of dosing, resolve within 2 weeks, and usually occur peripherally. These acute neuropathies occur in almost all patients to some degree and are exacerbated by exposure to cold temperature or cold objects. Healthcare providers should instruct patients to avoid cold drinks, avoid use of ice, and cover skin before exposure to cold or cold objects. In addition, carbamazepine, gabapentin, amifostine, and calcium and magnesium infusions have been used to both prevent and treat oxaliplatin-induced neuropathies, although the use of these agents is not widely accepted.[16] Persistent neuropathies generally occur after eight cycles of oxaliplatin and are characterized by defects that can interfere with daily activities (eg, writing, buttoning, swallowing, and walking). Patients may receive predefined breaks from oxaliplatin to decrease the onset of these toxicities with reinitiation of therapy.[26] This strategy varies among protocols but involves administering a certain number of predefined oxaliplatin cycles and then stopping. Maintenance therapy with another agent is usually administered and then the oxaliplatin-based regimen is restarted based on the protocol. These neuropathies occur in up to half of patients receiving oxaliplatin but usually resolve with dosage reductions or after oxaliplatin is stopped.[16] Oxaliplatin has minimal renal, myelosuppressive effects, and nausea and vomiting when compared with other platinum drugs. Oxaliplatin is given IV in a variety of dosing schedules with a typical dose of 85 mg/m^2 IV every 2 weeks.

Bevacizumab

Bevacizumab (Avastin) is a recombinant, humanized monoclonal antibody that inhibits VEGF. VEGF is a proangiogenic growth factor found in many cancers, including colorectal, and is thought to promote blood vessel formation and metastasis of the tumor by binding to VEGF receptors on tumors. Bevacizumab inhibits circulating VEGF, preventing it from binding to receptors and decreasing the formation of new blood vessels.[15,16] Additionally, bevacizumab may allow for increased concentrations of traditional chemotherapy such as irinotecan to reach the tumor to exert its pharmacologic effect. Bevacizumab is not effective alone and must be used in combination with other agents effective in colorectal cancer. It is indicated for first- and second-line treatment of patients with metastatic colorectal cancer in combination with IV 5-FU–based regimens. Bevacizumab is also approved for use in combination with 5-FU-irinotecan or 5-FU-oxaliplatin–based chemotherapy for treatment of patients with metastatic colorectal cancer whose disease has progressed on a first-line bevacizumab-containing regimen.

Adverse effects associated with bevacizumab include hypertension, which is common but easily managed with oral antihypertensive agents. Thrombotic events (including myocardial infarctions, pulmonary embolisms, and deep vein thrombosis) occur more frequently in the elderly patients with cardiovascular risk factors and need to be monitored carefully. Because bevacizumab interferes with normal wound healing, it should not be given shortly before or after surgical procedures.[15] Initiation within 28 days of surgery is not recommended to allow for proper wound healing and decrease the risk of bleeding. The amount of time needed after bevacizumab discontinuation to perform elective surgical procedures is less clear, but healthcare providers should take into consideration bevacizumab's half-life of approximately 20 days when making clinical decisions.[33] Patients should have their urine checked for protein before each dose of bevacizumab to check for potential kidney damage. Patients who have developed 2+

protein on the urinalysis require additional testing before receiving therapy. These patients will have their 24-hour urine collected and assessed for protein. Therapy is interrupted if urine protein excretion exceeds 2 g/24 hours or more and resumed when urine protein excretion decreases to less than 2 g/24 hours.

Finally, there is a risk of GI perforation that is rare but potentially fatal. Patients complaining of abdominal pain associated with vomiting or constipation should be counseled to call their physician immediately. Bevacizumab is commonly given at a dose of 5 mg/kg IV every 14 days until disease progression. Once disease progresses and salvage chemotherapy is initiated, the benefit of continuing bevacizumab is unclear.

Ziv-aflibercept

Ziv-aflibercept (Zaltrap) is a soluble recombinant fusion protein developed by fusing sections of the VEGFR-1 and VEGFR-2 immunoglobulin domains to the F_c portion of human IgG1 antibody. This results in trapping the VEGF-A, VEGF-B, and PIGF ligands before they get to the native transmembrane receptors, and, therefore, inhibiting the angiogenic process.[15,45] It is FDA approved for the treatment of metastatic colorectal cancer in combination with FOLFIRI after progression on an oxaliplatin-based regimen. The dose is 4 mg/kg as an IV infusion over 1 hour every 2 weeks in combination with FOLFIRI.

Toxicities include severe and potentially fatal hemorrhage, GI perforation, and compromised wound healing for which the FDA has given ziv-aflibercept a black-box warning. Other adverse effects common to VEGF inhibition (thromboembolic events, hypertension, and proteinuria) are seen. As a result, ziv-aflibercept shares similar monitoring parameters and warnings to those mentioned in the bevacizumab section. Finally, additional warnings for neutropenia, diarrhea and dehydration, and reversible posterior leukoencephalopathy syndrome (RPLS) require monitoring patients for signs and symptoms of these toxicities.

Ramucirumab

Ramucirumab (Cyramza) is a fully human IgG-1 monoclonal antibody that targets and binds to the VEGFR-2, inhibiting ligand activation of the receptor and subsequent vascular tumor growth.[46] For the treatment of colorectal cancer, ramucirumab is FDA-approved at a dose of 8 mg/kg IV in combination with FOLFIRI in patients who have progressed on or after therapy with 5-FU, oxaliplatin, and bevacizumab.

Ramucirumab shares an adverse effect profile similar to that of the previously discussed VEGF inhibitors bevacizumab and ziv-aflibercept, including black-box warnings for risk of hemorrhage, GI perforation, and impaired wound healing.

Regorafenib

Regorafenib (Stivarga) is an oral medication that inhibits multiple protein kinases. Its main mechanism of action in colorectal cancer appears to be related to the inhibition of vascular endothelial receptors involved in angiogenesis. The importance of additional protein kinase inhibited by regorafenib is unknown in colorectal cancer. Regorafenib is FDA approved as a single agent for metastatic colorectal cancer in the third- or fourth-line setting.[47] The dose of regorafenib is 160 mg orally, once daily for the first 21 days of each 28-day cycle and it must be taken with a low-fat breakfast to improve absorption.

Adverse effects for regorafenib include those typical for VEGF inhibition (hemorrhage, hypertension, wound healing complications, and GI perforation) mentioned with bevacizumab and ziv-aflibercept. Regorafenib has a black-box warning for hepatotoxicity that requires baseline liver function tests (ALT, AST, and bilirubin), then every 2 weeks during the first 2 months of therapy, and then monthly. In patients with elevated liver function tests holding doses, dose reductions, or permanent discontinuation of regorafenib may be necessary. Also, asthenia, fatigue, decreased appetite, hand–foot syndrome, diarrhea, mucositis, weight loss, infection, and dysphonia occurred in over 30% of patients. Refer to Chapter 99 on supportive care for management. Finally, regorafenib is a substrate of CYP3A4 and patients should be screened for potential drug interactions.

Cetuximab and Panitumumab

Cetuximab (Erbitux) and panitumumab (Vectibix) are monoclonal antibodies directed against the EGFR. Cetuximab is a chimeric antibody, whereas panitumumab is a fully human monoclonal antibody. EGFR is overexpressed in colorectal cancers and leads to an increase in tumor proliferation and growth. Cetuximab received FDA approval for use in *RAS* WT, EGFR-expressing metastatic colorectal cancer in irinotecan-relapsed or irinotecan-refractory patients. Cetuximab should be administered in combination with irinotecan but can be used as a single agent in patients who cannot tolerate irinotecan-based chemotherapy. Panitumumab is approved as monotherapy agent and as first-line therapy in combination with FOLFOX in *RAS* WT metastatic colorectal cancer.

Both agents are well tolerated with infusion-related reactions being the dose-limiting toxicity of cetuximab and rash most commonly seen with panitumumab. Patients receiving cetuximab require premedication with diphenhydramine and may require modifications to their administration schedule or permanent discontinuation if they develop severe allergic toxicity. A skin rash and diarrhea are also commonly seen with both agents, and healthcare practitioners should provide counseling to patients about these adverse effects. Treatment options include common medications used to treat acne (doxycycline), topical and systemic steroids, and general skin care. Patients may be offered these agents prophylactically, upon initiation of therapy, to decrease the potential impact the rash has on their quality of life. Development of rash may be a surrogate marker of response, and clinicians should attempt to minimize the complications of the rash before discontinuing therapy.[15] Other toxicities common to both agents include low magnesium, calcium, and potassium levels that require checking levels and replacement therapy as clinically indicated. A rare adverse effect (< 1%), interstitial lung disease is seen with all agents that inhibit EGFR, and patients should be instructed to report any new-onset shortness of breath. Cetuximab has an initial loading dose of 400 mg/m^2 IV infusion. Weekly doses of 250 mg/m^2 are then administered starting the following week. Panitumumab is given 6 mg/kg IV every 2 weeks.

Trifluridine and Tipiracil

Trifluridine/tipiracil (Lonsurf) is an oral agent that incorporates two components. The active component is trifluridine, a thymidine-based nucleic acid analog which is incorporated into DNA and interferes with DNA synthesis. Tipiracil hydrochloride inhibits TP and thereby prevents degradation of the active trifluridine and allows for adequate plasma concentration of active drug.[48] The FDA-approved dose of 35 mg/m^2 orally is based on the trifluridine component and is administered twice daily on days 1 to 5 and 8 to 12 of a 28-day treatment cycle. It is given as a single-agent in patients who have previously received 5-FU, oxaliplatin, irinotecan, anti-VEGF therapy, and anti-EGFR therapy (if *RAS* WT).

Adverse effects include myelosuppression (particularly neutropenia and anemia), fatigue, stomatitis, diarrhea, and nausea. Trifluridine/tipiracil has moderate emetic potential and pretreatment for nausea is recommended. Each dose should be taken within 1 hour of completion of the morning and evening meals. The unusual dosing schema of this agent may be difficult for some patients and negatively affect compliance, thus careful counseling and written dosing guidelines should be offered to all patients.

Pembrolizumab

Pembrolizumab is a humanized IgG4 monoclonal antibody that inhibits the programmed death 1 (PD-1) receptor to prevent ligand binding and subsequent pathway activation. The PD-1 pathway is an immune pathway that typically serves as a negative feedback system to suppress T-cell response. Many tumors upregulate the PD-1 pathway to encourage immune suppression and prevent host immune activity against tumor cells.[49] Pembrolizumab blocks this negative feedback mechanism to induce T-cell activation and subsequent antitumor immune response. Pembrolizumab is FDA approved in colon cancer patients with dMMR or MSI-H tumors after failure of standard chemotherapies. Patients with dMMR tumors typically have many mutations resulting in production of many abnormal proteins that serve as antigens to the immune system. Reactivation of the immune system by pembrolizumab is often an effective strategy in these patients. Pembrolizumab is given intravenously at a flat dose of 200 mg every 3 weeks for up to 24 months. Adverse effects are mainly related to overactivation of the immune system. Though most patients tolerate it quite well, patients may exhibit immune-mediated toxicity in nearly any organ in their body, particularly dermatitis, colitis, and endocrinopathies.[15,49] These and most other immune-mediated toxicities must be managed by temporary or permanent drug discontinuation and initiation of oral corticosteroids.

RECTAL CANCER

Although often treated similarly to colon cancer, there are some important differences in the treatment of rectal cancer, especially in the adjuvant setting. Rectal cancer involves tumors found in the distal 15 cm of the large bowel and, as such, is very distinct from colon cancer in that it has a propensity for both local and distant recurrence. The higher incidence of local failure and poorer overall prognosis associated with rectal cancer are attributable to limitations in surgical techniques. Therefore, multimodality therapies with a combination of chemotherapy, radiation, and surgery are at the forefront in the treatment of rectal cancer with the main goal of survival and quality of life by preserving the function of the anal sphincter. In addition, because treatment with surgery, radiation, or systemic chemotherapy at the time of the recurrence is often suboptimal, adjuvant therapy after tumor resection is an important aspect of treatment of the primary tumor. Similar to adjuvant therapy for colon cancer, 5-FU provides the basis for chemotherapy regimens for rectal cancer.

KEY CONCEPT Adjuvant therapy consisting of 5-FU–based chemotherapy in combination with radiation therapy should be offered to patients with stage II or III cancer of the rectum.[50] Radiation therapy decreases the rate of local recurrences, but 5-FU decreases the risk of distant tumor recurrence as well as acting as a radiosensitizer. Toxicities from combined modality therapy include severe hematologic toxicity, enteritis, and diarrhea. Additional trials have sought to determine optimal combinations of concurrent radiation and 5-FU. Similar to tumors in the colon, continuous infusions of 5-FU appear to be superior to bolus doses. However, leucovorin does not appear to improve efficacy of adjuvant treatment for rectal cancer. The use of oral alternatives to 5-FU that are also known to enhance radiation effects, such as capecitabine, are under investigation with preliminary data suggesting the combination of capecitabine and radiation is likely to be safe and effective. In addition, based on the efficacy in colon cancer, FOLFOX regimens have moved into clinical trials in the adjuvant setting.

Another unique aspect of rectal cancer is the use of neoadjuvant therapy. Preoperative radiation (with or without chemotherapy) is given to downstage the tumor before surgical resection to improve sphincter preservation.[50]

KEY CONCEPT Metastatic rectal cancer is treated with similar regimens as outlined in the colon cancer section that are used for palliation of symptoms.[50]

Patient Encounter Part 4

Despite completing six cycles of adjuvant chemotherapy, this patient's disease progresses, and a CT scan reveals metastases to his liver. The tumor is sent for pharmacogenomic profiling and is found to have the wild-type *KRAS* gene.

What pharmacologic treatment options are available for the treatment of his metastatic disease?

OUTCOME EVALUATION

The goals of monitoring are to evaluate whether the patient is receiving any benefit from the management of the disease, detect recurrence, and minimize the adverse effects of treatment. During treatment for active disease, patients should undergo monitoring for measurable tumor response, progression, or new metastases; these tests may include chest CT scans or X-rays, abdominal or pelvic CT scans or X-rays, depending on the site of disease being evaluated for response; and carcinoembryonic antigen (CEA) measurements every 3 months if the CEA level is or was previously elevated.[17] A positron emission tomography (PET) scan can be considered to identify localized sites of metastatic disease when a rising CEA level suggests metastatic disease but results of CT scans and other imaging studies are negative. Symptoms of recurrence such as pain, changes in bowel habits, rectal bleeding, pelvic masses, anorexia, and weight loss develop in fewer than 50% of patients. Patients who undergo curative surgical resection, with or without adjuvant therapy, require close follow-up because early detection and treatment of recurrence could still result in patient cures. In addition, early treatment for asymptomatic metastatic colorectal cancer appears superior to delayed therapy. Colorectal cancer surveillance guidelines published by the American Society of Clinical Oncology recommend against routinely monitoring liver function tests, complete blood count (CBC), FOBT, CT scans, annual chest X-rays, or pelvic imaging in asymptomatic patients.

In addition, a CBC should be obtained before each course of chemotherapy administration to ensure that hematologic values are adequate. In particular, white blood cell counts and absolute neutrophil counts can be decreased in patients receiving chemotherapy such as irinotecan and 5-FU. Baseline liver function tests and an assessment of renal function should be evaluated before and periodically during therapy. Other selected laboratory tests include checking for the presence of protein in the urine in patients receiving bevacizumab and monitoring of magnesium, calcium, and potassium in patients receiving cetuximab or panitumumab.

Patients should be evaluated during every treatment visit for the presence of anticipated side effects from their treatment, and healthcare practitioners should anticipate these adverse reactions and aggressively treat and prevent them from occurring. These generally include loose stools or diarrhea from irinotecan, 5-FU, and capecitabine; hand–foot syndrome from 5-FU and capecitabine; nausea or vomiting from irinotecan, 5-FU, and oxaliplatin; mouth sores from 5-FU; neuropathies from oxaliplatin; bleeding and hypertension from bevacizumab; and skin rash associated with cetuximab and panitumumab.

SUMMARY

Recent advances in the treatment of cancer of the colon and rectum now offer the potential to improve patient survival, but for many patients, improved DFS and PFS represent equally important therapeutic outcomes. In the absence of the ability of a specific treatment to demonstrate improved survival, important outcome measures should include the effects of the treatment on patient symptoms, daily activities, PS, and other quality-of-life indicators. Individualized patient care to balance the risks associated with treatment and benefits of a specific treatment regimen is necessary to optimize patient outcomes.

Patient Care Process

Collect Information:

- Perform a medication history for the use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings. Identify the stage of malignancy.
- Review patient-specific factors, tumor-specific factors, and laboratory information that may influence chemotherapy selection and drug dosing.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.
- Compile a list of appropriate chemotherapy treatment regimens.

Assess the Information:

- Determine the goal of therapy and prognosis based on stage of disease.
- Review the medication history (including prescription and OTC medications) to identify agents that may worsen the patient's symptoms of colon cancer. Identify agents that effect bowel function (resulting in diarrhea or constipation) or agents such as NSAIDs that may cause GI bleeding.
- Determine whether the patient is taking any substance that could potentiate chemotherapy toxicities or interact with prescribed medications.
- Based on the medical history, determine whether the patient has compelling indications or contraindications for specific chemotherapy.
- Review relevant laboratory tests (eg, CBC, electrolytes, complete metabolic panel to determine liver and hepatic function, tumor markers, and tumor genetic profile) which might impact drug selection or dosing.
- Identify a list of the potential appropriate chemotherapy regimens and the related toxicities.
- Determine supportive care needs including nausea and vomiting control, pain management, prevention of infections, electrolyte supplementation, and toxicity management.
- Determine PS of the patient (see Chapter 88).

Develop a Care Plan:

- Review the chemotherapy order and assess efficacy, dosages, drug interactions, and possible adverse effects from the regimen (see Tables 91–3 and 91–5).

Implement the Care Plan:

- Discuss lifestyle modifications that may assist in symptom and disease management.
- Calculate the body surface area (BSA) and determine if doses are optimal and correct for this patient. Evaluate laboratory values to assist in this process.
- Review supportive care options to decrease the impact of adverse effects for this patient (see Chapters 88 and 99).
- Determine whether the patient has insurance coverage or whether recommended agents are included on the institution's formulary.
- Counsel patient on potential adverse effects of the regimen.

Follow-up: Monitor and Evaluate:

- Follow up when the patient is scheduled for their next round of chemotherapy. Assess the patient for adverse effects of the regimen or other supportive care measures that may need to be added (eg, pain management).
- Review medication history, physical examination, laboratory results, and other imaging and diagnostic tests to evaluate if the patient should continue on their current chemotherapy regimen.

Abbreviations Introduced in This Chapter

APC	Adenomatous polyposis coli
CapeOX	Capecitabine and oxaliplatin
CBC	Complete blood count
CEA	Carcinoembryonic antigen
COX-2	Cyclooxygenase-2
CTC	Computed tomographic colonography
dMMR	DNA mismatch repair
DFS	Disease-free survival
DPD	Dihydropyrimidine dehydrogenase
EGFR	Epidermal growth factor receptor
FAP	Familial adenomatous polyposis
FIT	Fecal immunochemical test
FOBT	Fecal occult blood test
FOLFIRI	Folinic acid, fluorouracil, and irinotecan
FOLFOX	Folinic acid, fluorouracil, and oxaliplatin
GI	Gastrointestinal
HNPCC	Hereditary nonpolyposis colorectal cancer
INR	International normalized ratio
MSI	Mircrosatellite instability
NSAID	Nonsteroidal anti-inflammatory drug
PET	Positron emission tomography
PFS	Progression-free survival
PS	Performance status
TNM	Tumor, node, metastasis
TP	Thymidine phosphorylase
UGT	UDP-glucuronosyltransferase
VEGF	Vascular endothelial growth factor

Prostate Cancer

Amber B. Cipriani and Daniel J. Crona

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify risk factors associated with prostate cancer development.
2. Discuss the benefits and risks associated with prostate cancer screening.
3. Appraise the prognostic- and patient-specific data needed to determine appropriate treatment options.
4. Evaluate pharmacotherapeutic treatment options for patients with localized prostate cancer, metastatic **castration-sensitive prostate cancer** (mCSPC), nonmetastatic **castration-resistant prostate cancer** (nmCRPC), and metastatic castration-resistant prostate cancer (mCRPC).
5. Recognize common adverse effects and formulate a monitoring plan for patients receiving androgen deprivation therapy for prostate cancer based on patient-specific factors and the prescribed regimen.
6. Recognize the common adverse effects and formulate a monitoring plan for patients receiving treatment for metastatic prostate cancer.
7. Identify patients who are eligible for targeted treatment with poly (adenosine diphosphate-ribose) polymerase (PARP) inhibitors or immune checkpoint inhibitors based on molecular testing results.
8. Provide recommendations for bone health for patients undergoing treatment for prostate cancer.

INTRODUCTION

KEY CONCEPT Prostate cancer is the most frequently diagnosed cancer among men in the United States and represents the second leading cause of cancer-related deaths in all men.[1] The disease course ranges from indolent, asymptomatic tumors that may not require treatment to rapidly progressing, aggressive tumors that result in distant metastases, morbidity, and mortality.

EPIDEMIOLOGY AND ETIOLOGY

In the United States alone, it is estimated that 248,530 new cases of prostate cancer will be diagnosed, and more than 34,130 deaths will occur in 2021. Although prostate cancer incidence increased during the late 1980s and early 1990s due to widespread **prostate-specific antigen (PSA)** screening, prostate cancer–related deaths declined beginning around 2000, but have been stable since 2013.[1]

Prostate cancer risk factors include age, race/ethnicity, and family history of prostate cancer (Table 92–1).[2] Age is the greatest predictor of risk, and while the disease is rare among men under age 40, the incidence sharply increases with each subsequent decade of life.[3] An evaluation of autopsies from men who died of unrelated causes revealed prostate cancer in 2%, 29%, 32%, 55%, and 64% of men in their third, fourth, fifth, sixth, and eighth decades of life, respectively.[4]

Race

The incidence of clinical prostate cancer varies across geographic regions. Scandinavian countries and the United States report the highest incidences of prostate cancer, while it remains relatively rare in Japan and other Asian countries.[2] African American men have the highest rate of prostate cancer in the world, and prostate cancer mortality among African Americans is approximately twice that observed among Caucasian patients. Hormonal, dietary, and genetic differences, as well as differences in access to health care, may contribute to the variability in prostate cancer incidence and mortality among different populations.[2] Testosterone, commonly implicated in the pathogenesis of prostate cancer, is 15% higher in African American men, when compared to Caucasian men. Japanese men demonstrate decreased activity of 5-α-reductase, when compared with African American and Caucasian men.[5,6] In addition, variations in the androgen receptor (*AR*) gene exist. *AR* transcription is inversely correlated with the length of trinucleotide (CAG) repeats in the *AR* transactivation domain. Shorter CAG repeat sequences have been found in African Americans, and thus a combination of increased testosterone and *AR* activation may account for the increased prostate cancer risk among African Americans.[5]

Family History

Men with a brother or father with prostate cancer have twice the risk of prostate cancer compared to the rest of the population, and 5% to 10% of all prostate cancers are thought to be inherited.[7] Carriers of germline mutations in one of 16 DNA repair genes (eg, *BRCA1*, *BRCA2*, and *CHEK2*) are known to have an increased risk of developing prostate cancer and now eligible for the treatment with poly (adenosine diphosphate [ADP]-ribose) polymerase (PARP) inhibitors.[8] **KEY CONCEPT** Germline genetic testing is now recommended for all men with metastatic, regional, or high to very high risk localized prostate cancer.[9]

Table 92–1

Risk Factors Associated With Prostate Cancer

Factor	Possible Relationship
Probable Risk Factors	
Age	> 70% of cases are diagnosed in men older than 65 years
Race	African Americans have a higher incidence and death rate
Genetic	Familial prostate cancer inherited in an autosomal dominant manner Germline mutations in 1 of 16 DNA repair genes (eg, *BRCA1, BRCA2, ATM,* and *CHEK2*) are associated with increased prostate cancer risk and severity
Possible Risk Factors	
Environmental	Clinical carcinoma incidence varies worldwide Latent carcinoma similar between regions Nationalized men adopt intermediate incidence rates between that of the United States and their native country
Occupational	Increased risk associated with cadmium exposure
Dietary	Mediterranean diet associated with reduced risk of prostate cancer Increased risk associated with high-meat and high-fat diets Decreased intake of 1,25-dihydroxyvitamin D, lycopene, and β-carotene increases risk
Hormonal	Does not occur in castrated men Low incidence in cirrhotic patients Up to 80% are hormonally dependent African Americans have 15% increased testosterone Japanese have decreased 5-α-reductase activity Polymorphic expression of the androgen receptor gene

Other Factors

Benign prostatic hyperplasia (BPH) is common among elderly men, affecting more than 40% of men older than 70 years. BPH results in urinary symptoms (eg, hesitancy and frequency). Because prostate cancer affects a similar age-group and often has similar presenting symptoms, the presence of BPH often complicates the diagnosis of prostate cancer, although it does not appear to increase the risk of prostate cancer.[6] Smoking has not conclusively been associated with an increased risk of prostate cancer, but smokers with prostate cancer have an increased mortality from the disease, when compared with nonsmokers with prostate cancer.[6]

PATHOPHYSIOLOGY

The prostate gland is a solid, walnut-shaped organ positioned between the neck of the bladder and the urogenital diaphragm (Figure 92–1). More than 95% of prostate cancer cases are adenocarcinomas.[10] Rarer tumor types include small cell neuroendocrine cancers, sarcomas, and transitional cell carcinomas.

Prostate cancer can be graded systematically according to the histologic appearance of the malignant cell and then categorized into well-, moderately, or poorly differentiated grades.[10,11] Gland architecture is examined and then rated on the Gleason scale of 1 (well-differentiated) to 5 (poorly differentiated). At least two different specimens are examined, and the score for each specimen is added together. Groupings for total Gleason score are 2 to 4 for well-differentiated, 5 to 6 for moderately differentiated, and 7 to 10 for poorly differentiated tumors. Poorly differentiated tumors grow rapidly (poor prognosis), while well-differentiated tumors grow slowly (better prognosis).

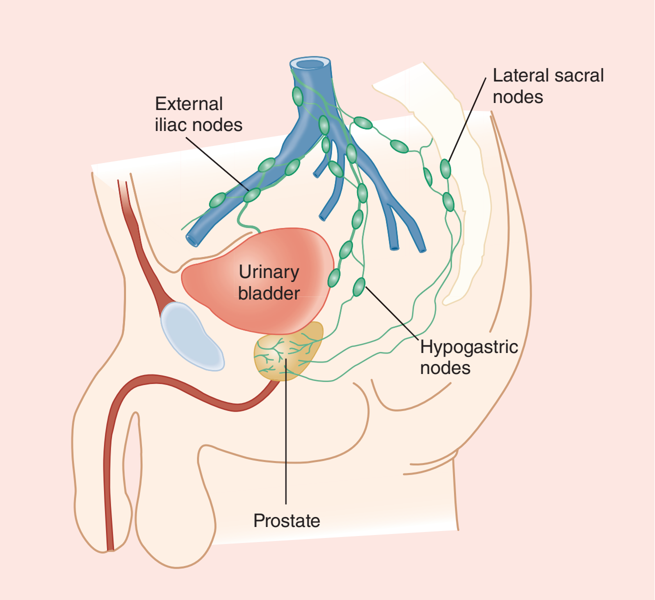

FIGURE 92–1. The prostate gland. (From DiPiro JT, Yee GC, Posey M, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 11th ed. New York, NY: McGraw-Hill, 2020:2304.)

Metastatic spread can occur by local extension, lymphatic drainage, or hematogenous dissemination.[10,11] Lymph node metastases are more common in patients with large, undifferentiated tumors that invade the seminal vesicles. Pelvic and abdominal lymph nodes are the most common sites of lymph node involvement (see Figure 92–1). Osseous skeletal metastases from hematogenous spread are the most common sites of distant spread. The most common site of bone involvement is the lumbar spine. The lung, liver, brain, and adrenal glands are the most common sites of visceral involvement; however, initial metastatic invasion does not occur in visceral organs, and the prostate is rarely a site for the metastatic spread of other solid tumors.

Normal growth and differentiation of the prostate depends on the presence of androgens, specifically dihydrotestosterone (DHT).[11,12] The testes and the adrenal glands are the major sources of circulating androgens. Hormonal regulation of androgen synthesis is mediated through a series of biochemical interactions among the hypothalamus, pituitary, adrenal glands, and testes (Figure 92–2).

Testosterone, the major androgenic hormone, accounts for 95% of the androgen concentration.[12] The primary source of testosterone is the testes; however, 3% to 5% of testosterone is derived from direct adrenal cortical secretion of testosterone or C19 steroids such as androstenedione.[11] In the prostate, 5-α-reductase converts testosterone to a more active form, DHT, and DHT is the active ligand that binds and activates the AR.

In early-stage prostate cancers, aberrant tumor cell proliferation is promoted by DHT-induced activation of the AR signaling axis. Blockade and reduction of circulating androgens can induce tumor regression in most patients. Hormonal manipulations to reduce circulating androgens can occur through several mechanisms (Table 92–2).[13,14] The testes can be removed surgically

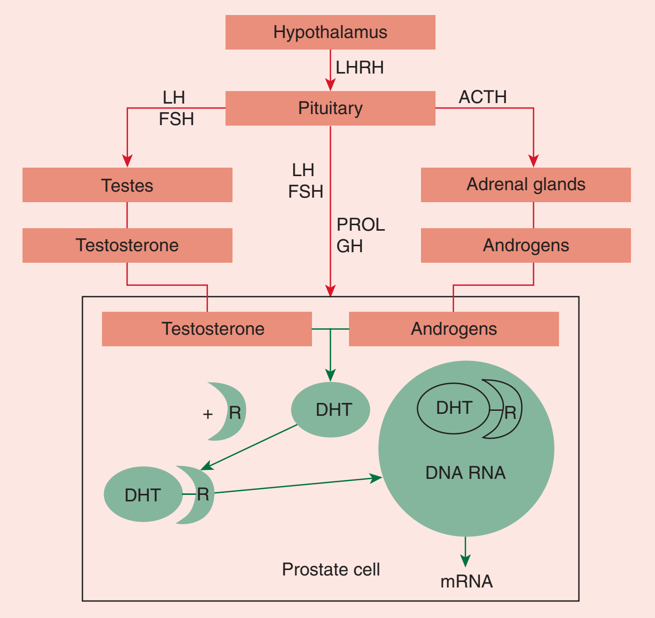

FIGURE 92–2. Hormonal regulation of the prostate gland. (ACTH, adrenocorticotropic hormone; DHT, dihydrotestosterone; DNA, deoxyribonucleic acid; FSH, follicle-stimulating hormone; GH, growth hormone; LH, luteinizing hormone; LHRH, luteinizing hormone–releasing hormone; PROL, prolactin; R, receptor; RNA, ribonucleic acid.) (orchiectomy) to limit androgen production, or chemical interference of hormonal pathways that modulate prostatic growth can be accomplished at several steps using androgen deprivation therapy (ADT) (see Figure 92–2). Reduction in the release of luteinizing hormone (LH) and LH-releasing hormone (LHRH) (also known as gonadotropin-releasing hormone [GnRH]) by estrogens, LHRH agonists, direct GnRH antagonists, progesterones, and cyproterone acetate can also reduce testosterone secretion from the testes.[11,14]

[a] Minor mechanisms of action.

[b] Investigational compounds or use.

GnRH, gonadotropin-releasing hormone; LH, luteinizing hormone; LHRH, luteinizing hormone–releasing hormone.

The physiologic response to LHRH depends on both the dose and the mode of administration. Intermittent pulsed LHRH administration, which mimics the endogenous release pattern, results in sustained release of both LH and follicle-stimulating hormone (FSH); however, high dose or continuous infusions of LHRH inhibit gonadotropin release via receptor downregulation. Structural modification of the naturally occurring LHRH, combined with innovative delivery methods, has produced a series of LHRH agonists that cause a similar downregulation of pituitary receptors, and a decrease in testosterone production.[15] Androgen synthesis can also be inhibited in the testes or adrenal gland. Pregnenolone is the precursor substrate for all adrenal-derived steroids, including androgens, glucocorticoids, and mineralocorticoids. Abiraterone is a specific and potent inhibitor of CYP17A1, decreasing the conversion of pregnenolone to dehydroepiandrosterone (DHEA), a required precursor for testosterone. Ketoconazole, an imidazole antifungal agent, causes a dose-related reversible reduction in serum cortisol and testosterone concentration through a similar mechanism. Megestrol is a synthetic derivative of progesterone that also inhibits the synthesis of androgens. This inhibition appears to occur at the adrenal level, but circulating levels of testosterone are also reduced, suggesting that inhibition at the testicular level may also occur.[15]

The conversion of testosterone to DHT may be inhibited by 5-α-reductase inhibitors. However, antiandrogens inhibit the formation of the DHT–receptor complex and thereby interfere with androgen-mediated action at the cellular level. Antiandrogens, and not 5-α-reductase inhibitors, have demonstrated the most therapeutic utility in the treatment of prostate cancer.[15]

In advanced stages of the disease, prostate cancer cells may be able to survive and proliferate without the growth signals normally provided by circulating androgens. When this occurs, these tumors are referred to as castration-resistant prostate cancer (CRPC) (previously described as "hormone refractory" or "androgen independent"). Because tumors remain amenable to secondary hormonal manipulations, and because the reintroduction of androgens can continue to promote tumor growth, the term castration resistant more accurately reflects the clinical picture.

PREVENTION AND EARLY DETECTION

Screening

Early detection of potentially curable cancers is the goal of prostate cancer screening. For cancer screening to be beneficial, it must reliably detect cancer at an early stage and identify those cancers that would benefit from an early intervention to decrease

Patient Encounter 1: Prevention and Screening

A 62-year-old African American man with a medical history significant for BPH presents to the pharmacy for a refill of his finasteride. He wants to know what he can do to reduce his risk of prostate cancer. He has a family history of prostate cancer (paternal father died of prostate cancer at 84 years old) and breast cancer (his paternal grandmother died of breast cancer at 72 years old), but he has never been screened for prostate cancer.

What do you recommend for prostate cancer screening?

Do you recommend genetic testing for this patient?

mortality. Whether prostate cancer screening fits these criteria has generated considerable controversy.[16,17] Digital rectal examination (DRE) has been a recommended prostate cancer screening method since the early 1900s. Primary advantages of DRE include specificity for detecting prostate cancer (> 85%), low cost, safety, and ease of performance. However, DRE has only moderate sensitivity (approximately 60%), and is subject to interclinician variability.

KEY CONCEPT PSA is a useful marker for detecting prostate cancer at early stages, predicting outcome for localized disease, monitoring disease-free status, and monitoring response to treatment of advanced-stage disease. PSA is a member of the human kallikrein gene family of serine proteases. PSA is produced by columnar secretory cells in the prostate and plays a role in the liquefaction of seminal fluid. PSA levels are detected via a blood test, and levels greater than 10 ng/mL (10 mcg/L) are associated with prostate cancer. While the relative ease and noninvasive nature of the PSA test make it the preferred method for screening, the low specificity for prostate cancer detection is a significant limitation.[18,19] In addition to patients with prostate cancer, PSA may also be elevated in men who are smokers, cases of acute urinary retention, acute prostatitis, and prostatic ischemia or infarction, as well as in patients with BPH (an extremely common condition in men at risk of prostate cancer). PSA elevations between 4.1 and 10 ng/mL (4.1-10 mcg/L) cannot distinguish between BPH and prostate cancer, which limits the utility of PSA alone for the early detection of prostate cancer. Additionally, not all men with clinically significant prostate cancer have a serum PSA outside of the reference range.[16] Specific recommendations for screening vary amongst different professional organizations, ranging from recommendations against PSA screening all together to recommendations to initiate screening in high-risk men (eg, men as young as 45 years old) who have had a balanced discussion with their provider.

Chemoprevention

The use of 5-α-reductase inhibitors, such as finasteride and dutasteride, as chemopreventive strategies for prostate cancer has been debated for many years.[20,21] Both finasteride and dutasteride can falsely lower PSA by approximately 50%, which should be a consideration for clinicians initiating these medications. Although no prospective studies have validated PSA monitoring thresholds in patients receiving 5-α-reductase inhibitors, the PSA threshold can be lowered by 50% (eg, a PSA of 4 ng/mL [4 mcg/L] for a patient receiving dutasteride that would be equivalent to a PSA of 8 ng/mL [8 mcg/L] for a patient not prescribed 5-α-reductase inhibitor).

Data regarding the effectiveness of finasteride and dutasteride on reducing the risk of prostate cancer were assessed in individual studies, and then later evaluated in a comprehensive Cochrane Review of 41,638 patients.[20] The use of 5-α-reductase inhibitors reduced the risk of prostate cancer by 25% when compared to placebo; however, patients who were diagnosed with prostate cancer presented with higher-grade (Gleason 7–10) prostate tumors, when compared to those diagnosed from the placebo arm. Adverse effects observed more commonly in the 5-α-reductase inhibitor treatment arms included decreased libido, erectile dysfunction, and gynecomastia.

Based on the risk of development of more aggressive prostate tumors, combined with a lack of overall survival benefit and increased risk of adverse effects, the use of 5-α-reductase inhibitors for prostate cancer prevention is not recommended. The American Society of Clinical Oncology and the American Urological Association (AUA) guidelines recommend that asymptomatic men who have a PSA of 3 ng/mL or less, and continue to be screened with regular PSA levels, may benefit from a discussion of both the benefits (eg, possible reduced risk of prostate cancer) and potential risks (eg, adverse effects and the possibility of high-grade tumors) of 5-α-reductase inhibitor therapy.[22] Patients who are prescribed 5-α-reductase inhibitors for benign conditions (eg, lower urinary tract symptoms) may benefit from a similar discussion.

Table 92–3

Diagnostic and Staging and Classification Systems Workup for Prostate Cancer

Initial tests	DRE PSA TRUS (if either DRE is positive or PSA is elevated) Biopsy
Staging tests	Gleason score on biopsy specimen CBC Liver function tests Serum phosphatases (acid/alkaline) Excretory urography
Additional staging tests (dependent on tumor classification, PSA, and Gleason score)	Bone Scan Multiparametric MRI Lymph node evaluation Pelvic/abdominal CT ^{111}In labeled capromab pendetide scan Bipedal lymphangiogram Transrectal MRI

CBC, complete blood count; CT, computed tomography; DRE, digital rectal examination; MRI, magnetic resonance imaging; PSA, prostate-specific antigen; TRUS, transrectal ultrasonography.

CLINICAL PRESENTATION AND DIAGNOSIS (TABLE 92–3)

KEY CONCEPT The prognosis for patients with prostate cancer depends on the histologic grade and stage of the prostate cancer. Details of staging are discussed in Chapter 88 and can also be

Clinical Presentation of Prostate Cancer

found in seminal guidelines.[9] One of the most important prognostic criteria appears to be the histologic grade, assessed by Gleason score, because poorly differentiated tumors ultimately impact disease staging. Poorly differentiated tumors are highly associated with both regional lymph node involvement and distant metastases.[10] Once the tumor has spread into regional lymph nodes, there is a significantly increased risk of disease recurrence after curative intent therapy. In order to complete a full diagnostic workup, patients should have a DRE, receive relevant imaging studies, undergo a biopsy for tissue diagnosis, obtain baseline PSA and testosterone levels, and participate in an interview to determine both relevant comorbidities (to determine life expectancy) and family history (to inform the need for germline genetic testing).[9]

TREATMENT

Desired Outcome

The desired outcome in early-stage prostate cancer is to minimize morbidity and mortality from prostate cancer, with an acceptance that some degree of morbidity may occur as a result of treatment.[9] Early-stage disease may be treated with surgery, radiation, or observation/active surveillance. Although surgery and radiation can be curative, they are associated with significant morbidity. Because the overall goal is to minimize morbidity and mortality associated with the disease, observation/active surveillance are appropriate in selected individuals who wish to avoid morbidity, or for whom aggressive interventions may not be clinically appropriate (eg, comorbid conditions). Advanced prostate cancer, where there is evidence of metastatic spread, is not curable. Treatment of advanced disease should focus on providing symptom relief and maintaining the quality of life. The cornerstone treatment for advanced prostate cancer is ADT, with the goal of reducing testosterone to castration levels through surgical or pharmacological treatment modalities.

General Approach to Treatment

The initial treatment for prostate cancer depends on the disease stage, Gleason score, presence of symptoms, and life expectancy of the patient.[9] Table 92–4 provides details of the recurrence risk stratification and recommended treatment options based on prognosis and life expectancy for patients who present with localized prostate cancer. The backbone of treatment for patients, at low-to-intermediate risk of prostate cancer recurrence, is local therapy with radiation and/or surgery, rather than systemic treatment with medication. Given the indolent nature of many prostate cancers, monitoring patients with low-risk disease and limited life expectancy with observation is an option. For these patients, noncurative treatment would be considered at progression. In contrast to monitoring patients through observation, active surveillance implies that curative therapies with some expected morbidity would be pursued upon progression of disease. In patients who are of sufficient risk to warrant invasive procedures, radiation therapy (external beam or brachytherapy), or radical prostatectomy (with or without a pelvic lymph node dissection [PLND]) can be considered.[9] Because patients with asymptomatic, early-stage disease generally have an excellent 10-year survival rate, the immediate morbidities associated with prostatectomy or radiation must be balanced with the lower likelihood of dying from prostate cancer. In general, more aggressive treatments for early-stage prostate cancer are reserved for younger men, although patient preference is a major consideration in all treatment decisions.

Radical prostatectomy and radiation therapy are generally considered therapeutically equivalent for localized prostate cancer.[9] Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence. Nerve-sparing radical prostatectomy can be performed in many patients, and 50% to 80% regain sexual potency within the first year. Acute complications from radiation therapy include cystitis, proctitis, hematuria, urinary retention, penoscrotal edema, and impotence (30% incidence).[9,10] Chronic complications include proctitis, diarrhea, cystitis, enteritis, impotence, urethral stricture, and incontinence.[10] Because radiation and prostatectomy have significant and immediate morbidity compared with observation alone, some patients may elect to postpone therapy until they become symptomatic.

Systemic therapy with ADT can be considered in patients with unfavorable intermediate risk and can be combined with radiation treatment depending on the presence of lymph node metastases.

The management of patients with a high and very high risk of localized prostate cancer recurrence includes the use of systemic treatments, including ADT and other drugs, in addition to local therapy with radiation/surgery (Table 92–4). Choice of initial management of these patients should include consideration of patient symptom burden as well as life expectancy. Radiation tends to be most common in this patient population, although selected individuals with a low tumor volume may receive a radical prostatectomy, with or without PLND. The duration of treatment with ADT in patients with higher risk disease is longer than in those with low intermediate–risk disease. **KEY CONCEPT** Androgen deprivation with an LHRH agonist should be used in combination with radiation therapy for patients with high or very high risk, locally advanced prostate cancer to improve outcomes over radiation therapy alone.[28]

In patients who are found to have regional lymph node involvement of their prostate cancer, and who have a life expectancy of more than 5 years, ADT is the backbone of therapy and may be combined with radiation and/or abiraterone + prednisone. Secondary hormonal manipulations, therapies that target the AR signaling axis, cytotoxic chemotherapy, immunotherapy, radiopharmaceutical therapy, or best supportive care are used for patients who progress after initial therapy.[9]

Patient Encounter 2: Early-Stage Disease

A 70-year-old man was found to have an abnormal DRE. His PSA was found to be elevated at 22 ng/mL. A prostate biopsy was performed by TRUS, which revealed an adenocarcinoma with a Gleason score of 9 (4 + 5). His tumor was staged as T_{3a} (evidence of tumor extension outside the prostate). He has a medical history of hypertension but is otherwise healthy. He expresses a wish to pursue aggressive therapy.

How would you stratify this patient's risk of developing progressive or metastatic prostate cancer?

What testing would you recommend for this patient?

What treatment options would you consider for a patient with this level of risk of developing progressive or metastatic prostate cancer?

Table 92–4

Initial Management of Localized Prostate Cancer[9 a,b]

Recurrence Risk	Disease Features		Expected Survival (years)	Initial Therapy
Very Low	T_{1c} and Gleason ≤ 6 and PSA < 10 ng/mL (mcg/L) and < 3 biopsy cores positive with ≤ 50% cancer in each core and PSA density < 0.15 ng/mL/g		< 10 10–20 >20	Observation AS AS *or* RP *or* RT
Low	T_1–T_{2a} and Gleason ≤ 6 and PSA < 10 ng/mL (mcg/L)		< 10 >10	Observation AS *or* RP ± PLND *or* RT
Intermediate	Has one or more intermediate risk factors (IRF): • T_{2b}–T_{2c} • Gleason 7 • PSA 10–20 ng/mL (mcg/L)	**Favorable intermediate:** • 1 IRF • Gleason 3 + 4 • < 50% of biopsy cores positive	< 10 >10	Observation *or* RT AS *or* RT *or* RP ± PTLD
		Unfavorable intermediate: • 2–3 IRFs • Gleason 4 + 3 • ≥ 50% biopsy cores positive	< 10 >10	Observation *or* RT + 4–6 months of ADT *or* intensive RT ± 4–6 months of ADT RP ± PLND (with addition of RT and/*or* ADT depending on lymph node involvement) *or* RT + 4–6 months of ADT *or* intensive RT ± 4–6 months of ADT
High	T_{3a} or Gleason 8–10 or PSA > 20 ng/mL (mcg/L)		< 5 AND asymptomatic	Observation *or* ADT *or* RT
Very High **Locally Advanced**	$T_{3b–T4}$ or primary Gleason pattern 5 or > 4 cores with Gleason 8–10		≥ 5 OR with symptoms	RT + ADT (x1–3 years) *or* RP + PLND with addition of RT and/or ADT depending on lymph node involvement
Regional	Any T, N1, M0		< 5 AND asymptomatic ≥ 5 OR with symptoms	Observation *or* ADT ADT + RT *or* ADT + RT + abiraterone + steroid

[a] ADT = serum testosterone levels < 50 ng/dL (1.74 nmol/L).

[b] Medical, or surgical ADT are equivalent.

AS, active surveillance; ADT, androgen deprivation therapy; PLND, pelvic lymph node dissection; PSA, prostate-specific antigen; RP, radical prostatectomy; RT, radiation therapy.

Data from National Comprehensive Cancer Network. NCCN Clinical Practice Guidelines in Oncology—Prostate Cancer Version 02.2020. 2020. Available from: https://www.nccn.org/professionals/physician_gls/pdf/prostate.pdf (accessed August 16, 2020).

Nonpharmacologic Therapy

▶ *Observation/Active Surveillance*

Observation involves monitoring the course of the disease and initiating palliative treatment if cancer progresses or the patient becomes symptomatic. PSA and DRE testing are performed every 6 to 12 months, but invasive biopsies are not performed if progression is suspected. The goal of observation is to maintain quality of life in the setting of a prostate cancer diagnosis and is most appropriate in elderly, frail men with limited life expectancy. In subtle contrast, patients treated with active surveillance have the intent of initiating curative treatment approaches should the cancer appear to progress. PSA and DRE testing are performed every 6 to 12 months, and prompt biopsies are indicated if progression is expected. Active surveillance is employed in younger patients with long-life expectancies who want to delay the morbidity associated with curative treatments, such as surgery, radiation, or ADT.

▶ *Orchiectomy*

Bilateral orchiectomy, or surgical removal of the testes, is a form of ADT that rapidly reduces circulating androgens to castration levels (ie, serum testosterone levels < 50 ng/dL [1.7 nmol/L]).[9] However, many patients find this procedure psychologically unacceptable, while others are simply not surgical candidates because of age. Orchiectomy may be the preferred initial treatment for patients with impending spinal cord compression or ureteral obstruction.

▶ *Radiation*

The two commonly used methods for radiation therapy are external beam radiotherapy (EBRT) and brachytherapy.[27-29] In EBRT, doses of 75 to 79 Gray (Gy) are delivered in 35 to 41 fractions in patients with low-grade prostate cancer and up to 81 Gy for those with intermediate- or high-grade prostate cancer. Brachytherapy involves the permanent implantation of radioactive beads of 145 Gy of ^{125}iodine or 125 Gy of ^{103}palladium and is generally reserved for individuals with low-risk cancers. Radiation therapy may be used to treat local, or locally advanced prostate cancer with curative intent. In later stages of disease, short courses of EBRT can be used to palliate symptoms.[9,23]

▶ *Radical Prostatectomy*

Radical prostatectomy is performed in patients with resectable disease who are surgical candidates, and who require definitive therapy based on both risk factors and patient preference.

Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence. The procedure can be combined with a regional lymph node dissection to ensure that the disease has not extended to the local lymph nodes.

Pharmacologic Therapy for Early-Stage Disease

▶ *Luteinizing Hormone–Releasing Hormone Agonists*

LHRH agonists are a reversible method of ADT and as effective as orchiectomy in treating prostate cancer.[9,24] Currently, the list of approved LHRH agonists include leuprolide, leuprolide depot, leuprolide implant, triptorelin depot, triptorelin implant, histrelin LA, and goserelin acetate implant. Leuprolide can be administered every 4, 12, 16, or 24 weeks; goserelin every 4 or 12 weeks; triptorelin every 4, 12, or 24 weeks; and histrelin every 12 months. The leuprolide depot formulation contains leuprolide acetate in coated pellets. The dose is administered intramuscularly, and the coating dissolves at different rates to allow sustained leuprolide levels throughout the dosing interval. The goserelin implant contains goserelin acetate dispersed in a plastic matrix of D,L-lactic and glycolic acid copolymer and is administered subcutaneously. Hydrolysis of the copolymer material provides continuous release of goserelin over the dosing period. Triptorelin LA is administered as an intramuscular injection (11.25 mg) every 84 days. Triptorelin depot is a 3.75 mg formulation injected every 28 days. Histrelin LA is surgically implanted every 12 months.

Several randomized trials have demonstrated that leuprolide, goserelin, histrelin, and triptorelin are effective agents when used alone in patients with advanced prostate cancer.[14] Response rates of approximately 80% have been reported. The choice between the four LHRH agonists is usually made on the basis of cost, as well as patient and prescriber administration schedule preferences.

The most common adverse effects reported with LHRH agonist therapy include vasomotor symptoms, such as hot flashes, erectile dysfunction, decreased libido, and injection-site reactions. Long-term adverse effects include decreased bone mineral density and metabolic syndrome.[14] Disease flare within the first week of therapy can be caused by an initial induction of LH and FSH that is induced by the LHRH agonist, leading to an initial period of increased testosterone production. Tumor flare manifests clinically as an exacerbation of disease-related symptoms, primarily increased bone pain or urinary symptoms.[9] The reaction usually resolves after 2 weeks and has a similar onset and duration pattern for the various depot LHRH agonist formulations. Initiating an antiandrogen (see Table 92–2) prior to LHRH agonist administration, and continuing for 2 to 4 weeks, is a frequently used strategy to minimize initial tumor flare.

LHRH agonist monotherapy can be used as initial therapy for advanced prostate cancer, with response rates similar to orchiectomy.[9] A lower incidence of cardiovascular-related adverse effects associated with LHRH agonist therapy has been observed, when compared to estrogens. Patients should be advised that a tumor flare could occur in the first week but could be mitigated by the addition of an antiandrogen during that period. Caution should be exercised if initiating LHRH agonists in patients with the potential for ureteral obstruction or spinal cord impingement because irreversible complications may occur.

Another potentially serious complication of ADT is decreased bone mineral density, leading to an increased risk of osteoporosis, osteopenia, and skeletal fractures.[25] Men initiated on long-term ADT should generally have a baseline bone mineral density test and be initiated on calcium and vitamin D supplementation.[9]

▶ *Gonadotropin-Releasing Hormone Antagonists*

An alternative to LHRH agonists are GnRH antagonists, degarelix or relugolix.[26] These agents reversibly bind to GnRH receptors on cells in the pituitary gland, reducing the production of testosterone to castration levels. The major advantage of direct GnRH antagonists over LHRH agonists is the speed at which they can achieve the drop in testosterone levels; castration levels are achieved in 7 days or less (compared to 28 days with leuprolide), which eliminates the risk of tumor flare and the need to initiate a concomitant antiandrogen. Degarelix is equivalent to leuprolide in lowering testosterone levels for up to 1 year and is approved for the treatment of advanced prostate cancer. Degarelix is available as 40 and 20 mg/mL (mcg/L) vials for subcutaneous injection, and the starting dose is 240 mg followed by 80 mg every 28 days. The starting dose should be split into two 120 mg injections. Relugolix is an oral tablet that is superior to leuprolide in lowering testosterone levels over 100 days and approved in advanced prostate cancer. The first dose of relugolix is 360 mg on day 1, followed by 120 mg daily thereafter.

The most frequently reported adverse effects include injection-site reactions (degarelix only), including pain, erythema, swelling, induration, and nodules. Most adverse effects are transient and mild to moderate, leading to discontinuation in less than 1% of patients. Other adverse effects include liver function test (LFT) elevations and osteoporosis. Because of the risk of developing osteoporosis, calcium and vitamin D supplementation should be considered. Degarelix not approved in combination with antiandrogens.

▶ *Antiandrogens*

Antiandrogens bind cytosolic AR, thereby decreasing available binding sites for endogenous androgens to activate the AR. First-generation nonsteroidal antiandrogens are flutamide, bicalutamide, and nilutamide (Table 92–5). Monotherapy with first-generation antiandrogens is less effective than LHRH agonist therapy. Therefore, for advanced prostate cancer, all currently available antiandrogens are indicated only in combination with ADT: flutamide and bicalutamide are indicated in combination with an LHRH agonist, while nilutamide is indicated after **orchiectomy**.

The most common antiandrogen-related adverse effects are listed in Table 92–5. Diarrhea is reported more frequently with flutamide than bicalutamide. Few clinical trials have been conducted to directly compare the first-generation antiandrogens.[9]

▶ *Combined Androgen Blockade*

Although up to 80% of patients with advanced prostate cancer respond to initial hormonal manipulation, almost all patients progress within 2 to 4 years after initiating therapy. Two main mechanisms of androgen reactivation have been proposed: (1) the tumor could be heterogeneously composed of cells that are hormone dependent and hormone independent, or (2) the tumor could be stimulated by extratesticular androgens (including intratumoral synthesis of androgens) that are converted intracellularly to DHT. Combined androgen blockade (CAB), which is the combination of LHRH agonists or orchiectomy with first-generation antiandrogens, aims to interfere with multiple hormonal pathways to more completely ablate androgens.

Table 92–5

First-Generation Antiandrogens

Antiandrogen	Usual Dose	Adverse Effects
Flutamide	750 mg/day	Gynecomastia Hot flushes Gastrointestinal disturbances (diarrhea) Liver function test abnormalities Breast tenderness Methemoglobinemia
Bicalutamide	50 mg/day	Gynecomastia Hot flushes Gastrointestinal disturbances (diarrhea) Liver function test abnormalities Breast tenderness
Nilutamide	300 mg/day for first month; then 150 mg/day	Gynecomastia Hot flushes Gastrointestinal disturbances (nausea or constipation) Liver function test abnormalities Breast tenderness Visual disturbances (impaired dark adaptation) Alcohol intolerance Interstitial pneumonitis

Many studies have been performed comparing CAB with conventional medical or surgical castration. A meta-analysis of 27 trials revealed a small (3.2%), but statistically significant, improvement in 5-year survival for patients treated with CAB, when compared to ADT alone.[27] However, adverse effects are far more common in patients who receive CAB and include diarrhea, LFT elevations, and anemia. Because the benefits of CAB are relatively small, and the increased adverse effects are not insignificant, it is appropriate to use either LHRH agonist monotherapy or CAB as initial therapy for metastatic prostate cancer. CAB may be most beneficial for improving survival in patients with minimal disease and preventing tumor flare.[9] All other patients may be started on LHRH agonist monotherapy, and an antiandrogen may be added after several months if androgen ablation is incomplete, or if disease progression occurs despite a castration level of testosterone.[28]

There is a considerable debate about when to start ADT in advanced prostate cancer patients.[14] The original recommendation to start therapy when symptoms appeared was based on trials that revealed no overall survival difference between patients who started diethylstilbestrol (DES) initially versus those who crossed over to DES treatment when symptoms arose. More recent data demonstrate that early intervention, before symptoms appear, may be appropriate; however, this continues to be balanced by patient goals and quality of life considerations.[29]

Given the morbidity of ADT, intermittent dosing strategies that allow for a break in therapy to restore the quality of life (and some suggest possibly resensitize cancer cells to hormonal blockade) have been investigated. A meta-analysis of 15 separate studies representing over 6000 patients found intermittent ADT noninferior for the overall survival and revealed some improvements in quality of life scores, when compared to continuous ADT dosing.[30] Intermittent ADT should be considered in men who experience significant adverse effects from ADT, and who are willing to undergo more frequent PSA and testosterone monitoring during off-treatment periods.

Patient Encounter 3: Progressive disease

A 66-year-old man was initially diagnosed with localized prostate cancer 2 years ago. At that time, he was classified as high risk and chose to undergo EBRT with the addition of ADT. He was initiated on ADT (leuprolide). His PSA had been stable for some time but has begun to rise over the last 6 months. His PSA 2 months ago was 12 ng/mL, 1 month ago was 27 ng/mL, and today is 45 ng/mL. Imaging studies do not reveal any sites of metastatic disease. His testosterone level today is 10 ng/dL.

How would you characterize the patient's disease?

What pharmacotherapeutic options are available to the patient?

Pharmacologic Therapies in Recurrent and Metastatic Disease

Men who present with or develop metastatic disease while not actively receiving ADT are considered to have metastatic castration-sensitive prostate cancer (mCSPC). This population is treated differently than those who develop metastatic disease despite the use of ADT, known as CRPC. Treatment of men who present with highly aggressive or metastatic disease may involve combinations of ADT with second-generation antiandrogens or cytotoxic chemotherapy. Secondary (or salvage) therapies for patients who progress after their initial treatments depend on the treatment modalities initially employed. For patients diagnosed with localized prostate cancer recurrence, radiotherapy may be used for local disease recurrence after radical prostatectomy. Alternatively, ADT can be used in patients who progress after either radiation therapy or radical prostatectomy.[9,28] Table 92–6 describes the medications used to treat advanced/metastatic prostate cancer.

ADT in Recurrent and Metastatic Prostate Cancer

There is debate about when to initiate ADT in patients who receive local therapy (surgery or radiation) and experience rising PSA levels without radiographic evidence of progression, also known as biochemical recurrence. In these patients, clinicians are encouraged to consider PSA doubling time (eg, how quickly the PSA level is rising), patient life expectancy, the toxicity of ADT, and patient wishes while determining when to initiate ADT.[9]

In patients who progress after initial treatment with ADT alone, secondary hormonal manipulations may be considered. This may include adding an antiandrogen for a patient who either incompletely suppresses testosterone secretion with an LHRH agonist. In patients who progress during CAB, withdrawing antiandrogens, or using agents that inhibit the AR signaling axis, may be considered.[28]

KEY CONCEPT Antiandrogen withdrawal can provide additional symptomatic relief for patients who progress while receiving combined hormonal blockade with an LHRH agonist and an antiandrogen. For patients who receive CAB with an LHRH agonist

Table 92–6

Agents Used in the Treatment of Advanced Prostate Cancer

Drug	Usual Dose	Adverse Effects	Dose Adjustments
Androgen Synthesis Inhibitor			
Abiraterone + Prednisone	500 mg twice daily (1 hour before or 2 hours after a meal) 5 mg once or twice daily	Gastrointestinal disturbances (diarrhea), edema, hypokalemia, hypophosphatemia, hypertension, LFT abnormalities, hypertriglyceridemia	Hepatic Reduce starting dose to 250 mg/day for moderate hepatic impairment Child–Pugh class B), and avoid Child–Pugh class C; withhold treatment if AST/ALT > 5 × ULN or bilirubin > 3 × ULN; DDI Use cautiously with concomitant CYP3A4 inhibitors and inducers
Second-Generation Antiandrogens			
Apalutamide	240 mg PO once daily	Fatigue, hypertension, rash, hypothyroidism, fracture, risk of seizure	*No renal or hepatic dose adjustments* DDI Strong CYP3A4 and CYP2C19 inducer Weak CYP2C9, PGP, BCRP, and OATP1B1 inducer Substrate of CYP2C8 (major) and CYP3A4 (minor)
Darolutamide	600 mg twice daily with food	Fatigue, rash, pain in extremities, decrease in neutrophil count, increase in AST, increase in bilirubin	Renal Reduce dose to 300 mg twice daily for eGFR 15–29 mL/min, not studied in eGFR < 15 mL/min Hepatic Reduce dose to 300 mg twice daily for moderate impairment; not studied in severe impairment DDI Weak CYP3A4 inducer Weak BCRP, OATP1B1 inhibitor Substrate of CYP3A4 (minor), PGP,(minor), UGT1A1, UGT1A9
Enzalutamide	160 mg PO once daily	Gastrointestinal disturbances (diarrhea), musculoskeletal issues (eg, arthralgias and myalgias), asthenia, fatigue, peripheral edema, LFT abnormalities, seizures, PRES	*No renal or hepatic dose adjustments* DDI Strong CYP3A4 inducer Moderate CYP2C9 and CYP2C19 inducer Avoid CYP3A4, CYP2C9, and CYP2C19 sensitive substrates Avoid strong inducers and inhibitors of CYP2C8
Cytotoxic Chemotherapy			
Cabazitaxel	20 mg/m^2 IV every 3 weeks	Fluid retention, constipation, mucositis, myelosuppression, hypersensitivity	Hepatic Discontinue if patient ALT > 2 × ULN, or if patient develops jaundice DDI Avoid concomitant use of CYP3A4 inhibitors and inducers Hematologic Ensure CBC recovery prior to administration
Docetaxel	75 mg/m^2 IV every 3 weeks	Fluid retention, alopecia, mucositis, myelosuppression, hypersensitivity	Hepatic Do not administer if AST/ALT > 1.5 × ULN and ALP > 2.5 ULN DDI Avoid concomitant use of CYP3A4 inhibitors Hematologic Ensure CBC recovery prior to administration
Immunotherapy			
Pembrolizumab	200 mg IV every 3 weeks OR 400 mg IV every 6 weeks	Fatigue, muscle pain, pyrexia, pruritus, autoimmune toxicities (dermatitis, colitis, hepatitis, hypophysitis, hypothyroidism)	*No renal or hepatic dose adjustments* DDI The use of immunosuppressants may lessen the therapeutic effects
Sipuleucel-T	> 50 million autologous CD54+ cells obtained from leukapheresis. CD54+ cells are activated with PAP-GM-CSF. three total doses given	Hypersensitivity, chills, fever, fatigue, headache, and myalgias	*No renal or hepatic dose adjustments* DDI The use of immunosuppressants may lessen the therapeutic effects

(Continued)

Table 92–6

Agents Used in the Treatment of Advanced Prostate Cancer (*Continued*)

Drug	Usual Dose	Adverse Effects	Dose Adjustments
PARP Inhibitors			
Olaparib	300 mg PO twice daily	Fatigue, nausea, myelosuppression, nausea, secondary malignancy	Renal Reduce dose to 300 mg twice daily for eGFR 15–30 mL/min, not studied in eGFR < 15 mL/min DDI Avoid use with concomitant strong and moderate CYP3A4 inhibitors (if cannot be avoided then reduce olaparib dose). Avoid use with concomitant strong CYP3A4 inducers
Rucaparib	600 mg PO twice daily	Fatigue, nausea, myelosuppression, nausea, AST/ALT elevation, increased SCr, secondary malignancy	*No renal or hepatic dose adjustments* DDI Use cautiously with concomitant drugs that are also CYP1A2, CYP2C9, CYP2C19, and CYP3A4 substrates

ALP, alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; BRCP, breast cancer resistance protein transporter; CBC, complete blood count; CD, cluster of differentiation; CYP, cytochrome P450; DDI, drug–drug interaction; eGFR, estimated glomerular filtration rate; GM-CSF, granulocyte-macrophage colony-stimulating factor; IV, intravenous; LFT, liver function test; OATP, organic anion transporting polypeptide transporter; PARP, poly (ADP-ribose) polymerase; PGP, P-glycoprotein transporter; PO, oral; PRES, posterior reversible encephalopathy syndrome; SCr, serum creatinine; UGT, uridine 5′-diphospho-glucuronosyltransferase; ULN, upper limit of normal.

and an antiandrogen, antiandrogen withdrawal can be the first salvage manipulation.[9,28] Somatic genetic mutations in *AR* arise in patients treated with antiandrogens and cause these agents to exhibit receptor agonist properties. Objective and subjective responses have been reported in patients following antiandrogen discontinuation from their CAB regimen. Patient responses to antiandrogen withdrawal manifest as significant PSA reductions and improved clinical symptoms. Antiandrogen withdrawal responses lasting 3 to 14 months have been reported in up to 35% of patients, and patient responses seem to closely correlate with longer antiandrogen exposure times.[28]

KEY CONCEPT When advanced prostate cancer progresses, despite castration levels of testosterone, it is known as CRPC. For patients who initially received an LHRH agonist alone, castration testosterone levels should be documented. Patients with inadequate testosterone suppression (eg, levels > 20 ng/dL [0.7 nmol/L]) can be treated by adding an antiandrogen, or performing an orchiectomy. If castration testosterone levels have been achieved, but symptoms of progression are evident or a PSA rise is observed, the patient's disease is considered to have progressed to CRPC. Because androgens remain a growth signal for the cancer, ADT is continued throughout the treatment course of CRPC, and the cancer may continue to respond to treatments that target the AR signaling axis (eg, enzalutamide or abiraterone).

KEY CONCEPT Second-generation therapies that target the AR signaling axis, such as abiraterone and enzalutamide, improve survival in patients with mCSPC, nonmetastatic CRPC (nmCRPC), and mCRPC (see Table 92–7).

▶ *Second-Generation Antiandrogens*

Despite initial responses to ADT and first-generation antiandrogens, disease progression eventually occurs. Second-generation antiandrogens not only inhibit the AR from binding its ligand, but they also prevent the AR from translocating into the cell nucleus, further inhibiting androgen signaling. Of note, second-generation antiandrogens are still combined with ADT (either a GnRH agonist/antagonist or orchiectomy) to obtain castration levels of testosterone in all treatment settings discussed below.

Apalutamide

Apalutamide is a second-generation antiandrogen that binds directly to the ligand-binding domain of the AR, inhibits nuclear

Table 92–7

First-Line Treatment Options for Advanced and Metastatic Prostate Cancer

	Locally Advanced/ Nonmetastatic	Metastatic
Castration Naïve (ADT *initiated* to achieve testosterone < 50ng/mL in all cases)	• ADT	• ADT • ADT + apalutamide • ADT + enzalutamide • ADT + abiraterone + prednisone • ADT + docetaxel
Castration Resistant (ADT *continued* to maintain testosterone < 50 ng/mL in all cases)	• Apalutamide • Darolutamide • Enzalutamide	• Enzalutamide • Abiraterone + prednisone • Docetaxel + prednisone • Sipuleucel-T • Radium-223 (if symptomatic bone mets) • Mitoxantrone (if symptomatic with visceral mets and cannot tolerate other treatments)

ADT, androgen deprivation therapy; mets, metastases.

translocation of AR, inhibits DNA binding of the AR, and prevents AR-mediated transcription. Apalutamide was compared to placebo in 1052 men with mCSPC in the TITAN trial. All men in the trial received either medical or surgical castration. In this patient population, apalutamide demonstrated improved progression free survival (PFS) and overall survival (OS) at 24 months.[31]

In men with nonmetastatic CRPC, apalutamide + ADT demonstrated an improvement in metastasis-free survival compared to placebo in the SPARTAN trial. Notably, the rate of adverse events leading to discontinuation in this study was 10.6% in the apalutamide group versus 7.0% in the placebo group, underscoring the relatively good tolerability of the agent.[32] Apalutamide is associated with rash, fatigue, hypertension, and a risk of fracture and seizure. Compared to the other antiandrogens, apalutamide has an increased risk of hypothyroidism. Care should be taken to screen patients for drug–drug interactions (DDIs) (see Table 92–6), as apalutamide is a strong inducer of CYP3A4 and CYP2C19. Common drug interactions include statins, DOACs, PPIs, clopidogrel, and citalopram.

Darolutamide

Darolutamide is another second-generation antiandrogen that competitively inhibits ligand binding to the AR while also inhibiting nuclear translocation and AR-mediated transcription. Compared to other second-generation antiandrogens, daralutamide has fewer effects on CYP enzymes, resulting in fewer drug interactions (see Table 92–6). The drug also has lower central nervous system penetrance compared to enzalutamide and apalutamide, resulting in a lower risk of fatigue and seizures. Darolutamide + ADT was compared to placebo + ADT in men with nmCRPC in the ARAMIS trial and demonstrated an improved metastasis-free survival.[33]

Enzalutamide

Enzalutamide was the first second-generation antiandrogen to obtain Food and Drug Administration (FDA) approval and has demonstrated efficacy in men with both CSPC and CRPC (see Table 92–6**).** In mCSPC, enzalutamide demonstrated improved metastasis-free survival compared to placebo in the ARCHES trial.[34] Enzalutamide has also demonstrated approved OS in nmCRPC in the PROSPER study.[35] In those with mCRPC, enzalutamide is an effective first-line treatment option in chemotherapy-naive patients, as well as a viable second-line option in patients who have failed prior to docetaxel chemotherapy.[36,37] Primary adverse effects include fatigue, diarrhea, hot flashes, musculoskeletal pain, and hepatotoxicity (ie, LFT elevations).[36,37] Seizures and posterior reversible encephalopathy syndrome are rare but serious adverse effects. Enzalutamide is a strong inducer and inhibitor of CYP3A4, as well as a moderate inducer and inhibitor of both CYP2C9 and CYP2C19, so DDIs are a consideration.

Patient Encounter 4: Metastatic disease at presentation

A 63-year-old man presents to clinic with severe abdominal and back pain. After a complete workup, he is diagnosed with metastatic prostate cancer, with evidence of metastatic disease in his lungs, liver, and bones (femur and spine). He has a PMH significant for hypertension (controlled on lisinopril and metoprolol), atrial fibrillation (currently on rivaroxaban), and restless leg syndrome (untreated, but currently controlled).

How would you characterize this patient's prostate cancer?

Which available pharmacotherapeutic options would be preferable for this patient?

▶ *Androgen Synthesis Inhibitors*

Despite ADT, androgen synthesis can continue to occur in the periphery (eg, adrenal glands) or via intratumoral synthesis. Androgen synthesis inhibitors, such as aminoglutethimide 250 mg orally every 6 hours or ketoconazole 400 mg orally three times daily, can provide symptomatic relief for a short time in approximately 50% of patients with progressive disease despite previous ADT.[38] With the advent of newer agents, their role in therapy has diminished substantially.

Abiraterone

Cytochrome P450 enzymes play a critical role in androgen synthesis. CYP17A1 inhibition prevents the conversion of pregnenolone to DHEA, a requisite precursor for testosterone. Abiraterone acetate is a potent and specific inhibitor of CYP17A1, resulting in further testosterone reductions, when combined with continued ADT. Abiraterone has demonstrated benefit in combination with ADT in CSPC as initial treatment in the LATITUDE study, as well as in mCRPC both before and after receipt of docetaxel chemotherapy.[9,39] Inhibition of CYP17A1 can result in mineralocorticoid excess, which underlies many of the adverse effects associated with abiraterone, and is the reason why it is always prescribed concomitantly with daily prednisone (given once daily in CSPC and twice daily in CRPC). Prednisone serves to prevent activation of a response to perceived cortisol deficit via negative feedback. Symptoms of mineralocorticoid excess include fluid retention, hypokalemia, and hypertension. Hepatotoxicity (eg, LFT abnormalities) is a less common but sometimes severe adverse effect. Abiraterone should be administered on an empty stomach (1 hour before or 2 hours after a meal), as food significantly increases absorption. As a CYP3A4 substrate, abiraterone should be used cautiously with concomitant CYP3A4 inhibitors and inducers (Table 92–6).

The need to take abiraterone twice daily on an empty stomach to avoid variation in drug exposure can lead to issues with adherence. A novel fine-particle formulation of abiraterone was developed that allows for once daily dosing of 500 mg with similar extent of abiraterone absorption and demonstrated clinical equivalence with regard to serum testosterone levels.[40] Fine-particle abiraterone must be administered with methylprednisolone once daily to prevent mineralocorticoid excess. The lack of long-term safety and efficacy data with this alternative formulation makes it an option mainly in patients who are not able to properly administer abiraterone.[9]

▶ *Chemotherapy*

KEY CONCEPT Chemotherapy with docetaxel improves survival in patients with mCSPC and mCRPC, particularly in patients with high disease burden. Chemotherapy with cabazitaxel improves survival in patients with mCRPC who have either progressed on or are intolerant to docetaxel.

Docetaxel

Docetaxel is an antimicrotubule taxane, which has been shown to improve survival in mCRSC patients when administered at 75 mg/m^2 every 3 weeks for six cycles in combination with ADT in the CHAARTED trial. Of note, the clinical benefit of docetaxel was more pronounced in patients with a higher burden of disease in this trial.[41] In men with mCRPC, docetaxel with prednisone 5 mg twice daily (to further inhibit adrenal steroid production in castration-resistant disease) demonstrated improved overall survival when compared to mitozantrone plus daily prednisone.[41] The most common adverse effects of docetaxel include nausea, alopecia, bone marrow suppression, fluid retention, and peripheral neuropathy. Premedication with dexamethasone is recommended to prevent fluid retention associated with docetaxel. Docetaxel undergoes extensive hepatic metabolism; patients with hepatic impairment may not be eligible for the treatment with docetaxel due to an increased risk of adverse effects (Table 92–6).

Cabazitaxel

Cabazitaxel is also an antimicrotubule taxane with demonstrated activity in docetaxel-resistant cell lines and animal models of human cancer. Low affinity for the P-glycoprotein efflux transporter, when compared to docetaxel, could conceivably be the reason why cabazitaxel remains effective in the setting of docetaxel resistance. In docetaxel-pretreated patients, cabazitaxel (25 mg/m^2 every 3 weeks with prednisone 10 mg/daily) significantly improved progression-free and overall survival compared with mitoxantrone and prednisone.[42] Later, the FDA approved a reduced cabazitaxel dose of 20 mg/m^2 every 3 weeks based on evidence of similar efficacy but better tolerability, when compared to 25 mg/m^2.[43] The most significant adverse effects associated with cabazitaxel include neutropenia, neuropathy, and diarrhea. Hypersensitivity reactions can occur with cabazitaxel, so premedication with an antihistamine, corticosteroid, and H$_2$ antagonist is recommended. Cabazitaxel undergoes extensive hepatic metabolism and should be avoided in patients with hepatic dysfunction. Cabazitaxel is a CYP3A4 substrate, so concomitant use of CYP3A4 inhibitors and inducers should be avoided as well (see Table 92–6).

▸ *Immunotherapy*

Sipuleucel-T is an autologous immunotherapy that was approved for patients with asymptomatic or minimally symptomatic mCRPC.[45] Eligible patients first undergo leukapheresis to collect peripheral blood mononuclear cells (the cellular fraction that contains dendritic cells), which are sent to a central processing laboratory. These are stimulated with a fusion protein of prostatic acid phosphatase (PAP) and granulocyte-macrophage colony-stimulating factor (GM-CSF). PAP is a specific tumor antigen, while GM-CSF is an immune cell activator. The cultured cells are then returned and infused into the patient. This procedure is performed every 2 weeks for a total of three treatments. Adverse effects associated with sipuleucel-T are generally mild to moderate and include transient chills, fever, and headache (see Table 92–6). Sipuleucel-T was shown to improve overall survival, when compared to placebo in men with mCRPC, but the trial excluded patients with visceral metastases.[44] Despite a modest improvement in survival, sipuleucel-T did not decrease the time to disease progression and thus does not offer significant relief from disease-related symptoms. It is not appropriate in symptomatic patients with rapidly progressing disease for whom treatments that delay tumor progression are feasible.

Immune checkpoint inhibitors are now being used broadly in a variety of cancers. Immune checkpoint inhibitors (PD1, PDL1, and CTLA4 inhibitors) work by inhibiting signals that lead to T-cell senescence and thus increase the immune response to cancer. Pembrolizumab, a PD1 inhibitor, is FDA approved for patients with metastatic solid tumors who have a high tumor mutation burden, defined as 10 or more mutation/megabase of DNA, or microsatellite instability-high (MSI-H) or mismatch repair deficient (dMMR) that are documented by molecular testing, who have progressed on prior treatment, and who have no alternative treatment options. Mismatch repair is deficient in tumor cells of 5% to 12% of men with mCRPC.[45] Molecular testing assays that can detect these abnormalities should be used to properly identify advanced and metastatic prostate cancer patients who may benefit from pembrolizumab.[9]

▸ *Poly(Adenosine Diphosphate-Ribose) Polymerase (PARP) Inhibitors*

Somatic and germline mutations that result in deficiencies of DNA repair genes are common in men with mCRPC.[45] PARP enzymes are involved in normal DNA repair. When PARP enzymes are inhibited in the setting of additional deficiencies in DNA repair by homologous recombination, genetic instability results in cell death. Olaparib has demonstrated efficacy in the treatment of mCRPC in patients who harbor deleterious germline or somatic mutations in DNA damage repair genes (*ATM*, *BRCA1*, *BRCA2*, *BARD*, *BRIP1*, *CDK12*, *CHEK1/2*, *FANCL*, *PALB2*, and *RAD51*). Patients treated with olaparib had progressed on enzalutamide or abiraterone (none had failed chemotherapy with docetaxel).

Table 92–8

Second-Line Treatment Options for mCRPC

	If Patient Received First-Line Abiraterone or Enzalutamide	If Patient Received First-Line Docetaxel:
Preferred regimens	• Docetaxel + prednisone	• Abiraterone + prednisone • Cabazitaxel + prednisone • Enzalutamide
Useful in certain patients	• Sipuleucel-T (if no visceral mets) • Olaparib (based on genetic testing) • Pembrolizumab (based on molecular testing) • Radium-223 (if symptomatic bone mets)	• Mitoxantrone (palliation in symptomatic patients) • Rucaparib (based on *BRCA* status) • Pembrolizumab (based on molecular testing) • Radium-223 (if symptomatic bone mets)
Other regimens	• Abiraterone + prednisone (if enzalutamide used previously) • Cabazitaxel + prednisone • Enzalutamide (if abiraterone used previously) • Fine-particle abiraterone + methylprednisolone • Rucaparib (based on *BRCA* status)	• Docetaxel + prednisone rechallenge • Fine-particle abiraterone + methylprednisolone • Sipuleucel-T (if no visceral mets) • Olaparib (based on genetic testing)

BRCA, breast cancer susceptibility gene; mCRPC, metastatic castration-resistant prostate cancer; mets, metastases.

Patient Encounter 5: Treatment of mCRPC

A 69-year-old man was diagnosed with localized prostate cancer 4 years ago. He initially underwent a radical prostatectomy. He experienced rising PSA on three separate clinic visits 1 year ago and was found to have metastatic disease in the lumbar spine. He was initiated on ADT + enzalutamide for the treatment of his mCSPC 1 year ago. He presents to clinic today with a rising PSA and evidence of new bone metastases on imaging. He complains of severe back and hip pain. His laboratory values today suggest normal organ function, a PSA of 102 ng/dL, and a testosterone of 4 ng/mL. A sample of his tumor was sent for next-generation sequencing, and he is found to have a microsatellite stable disease and no evidence of alterations in DNA mismatch repair genes. He did receive germline genetic testing that did not reveal any mutations in BRCA1/2.

What treatment options should be considered for this patient?

Radiological PFS was improved in the olaparib arm; however, this response appears to be driven by patients with *BRCA2* mutations.[46] A second PARP inhibitor, rucaparib, obtained FDA approval in patients with mCRPC who harbor germline or somatic DNA damage repair mutations (specifically in *BRCA1/2*) and have progressed after both ADT and taxane-based chemotherapy. Further characterization of favorable disease characteristics to predict response to PARP inhibitors is needed, and studies evaluating combination therapies are underway.[9]

▶ *Bone Protective Therapies*

Radium-223 is an alpha particle emitter and calcium-mimetic radiopharmaceutical that provides significant palliation to mCRPC patients with bone metastases.[47] Radium-223, infused every 4 weeks for six total treatments, has been shown to significantly improve the overall survival, as well as skeletal pain and patient quality of life. Common adverse effects are nausea, vomiting, peripheral edema, and moderate myelosuppression. Radium-223 has been associated with lower rates of myelosuppression compared to other alpha-emitting radiopharmaceuticals. Radium-223 is appropriate for first-, second-, or third-line treatment of patients with mCRPC and symptomatic bone pain.

Given the risk of fractures associated with ADT, bone health is an important aspect of prostate cancer management at all stages. All patients on ADT without metastatic disease should receive calcium and vitamin D supplementation, along with bone density studies based on patient Fracture Risk Assessment Tool (FRAX) risk score. Patients with elevated fracture risk scores may receive treatment with denosumab (60 mg subcutaneously every 6 months), zoledronic acid (5 mg intravenous [IV] every 12 months),

Patient Care Process

Collect Information:

- Obtain complete medical history, family history (including family cancer history), and social history.
- Obtain complete list of any concomitant prescription and over-the-counter medications; be sure to include herbal, vitamin, and mineral supplements.
- Verify completion of prostate cancer workup and staging, including PSA level, pathology results, and staging scans, if indicated.
- Discuss symptom burden with the patient to identify bothersome symptoms that should be addressed by treatment plan.
- Obtain labs to evaluate organ function in order to appropriately choose therapy plan.

Assess the Information:

- Identify prognostic factors that influence the development of metastatic prostate cancer.
- Stratify the patient of the risk with regard to the stage of disease, Gleason score, PSA level, comorbid conditions, and life expectancy.
- Assess laboratory values and organ function with regard to treatment options.
- Identify treatment-related morbidity that would be a barrier to adherence based on the patient's current symptoms and goals of care.

Develop a Care plan:

- Using cancer stage, risk level, and patient-directed goals of therapy, determine if drug therapy is indicated.
- Identify appropriate pharmacotherapy that maximizes efficacy while minimizing toxicity based on patient-specific comorbidities, organ function, and care goals.
- Assess cost of proposed therapies and ensure that they are affordable and reasonable for the patient.

Implement the Care Plan:

- Discuss the benefits and risks of appropriate treatment options with the healthcare team and patient.
- If drug therapy is selected, review patient medical history for drug–drug and drug–herbal interactions.
- Discuss clear goals of care with the patient.
- Initiate therapy.

Follow-up: Monitor and Evaluate:

- If patient is asymptomatic, monitor PSA and circulating androgens for castration level of testosterone. If patient is symptomatic, monitor symptoms for improvement or worsening. Obtain imaging studies to evaluate the response of distant metastases.
- Monitor for any new signs or symptoms of progression, and adverse effects from therapy. Evaluate adherence to ADT. Consider intermittent ADT if patient reports intolerance or significant decrease in the quality of life.
- Consider removal of antiandrogen if CAB approach is chosen and patient demonstrates progression.
- Consider PSA velocity and symptom burden when assessing for the need for treatment changes.

or alendronate (70 mg PO weekly) with the intention of increasing bone mineral density.[9]

Skeletal metastases from hematogenous spread are the most common sites of distant spread of prostate cancer. In men with CRPC who have bone metastases, both zoledronic acid (4 mg IV every 4 weeks or every 12 weeks) and denosumab (120 mg subcutaneously every 4 weeks) have been shown to decrease the incidence of skeletal-related events (fracture, spinal cord compression, or the need to surgery or radiation to the bone). While denosumab has demonstrated superiority over zoledronic acid in the prevention of skeletal-related events, denosumab also has an increased risk of hypocalcemia and thus may not be appropriate in all patients.[48] Both denosumab and zoledronic acid are associated with osteonecrosis of the jaw. Dental procedures should be avoided while receiving these agents, and dental screening prior to initiation is recommended.[9]

OUTCOME EVALUATION

Prostate cancer monitoring depends on the grade and stage of the cancer. When definitive, curative therapy is attempted, check objective parameters (eg, imaging studies, DRE) to assess tumor response and monitor PSA to assess for recurrence or progression. Following definitive therapy, PSA is checked every 6 months for the first 5 years and annually thereafter.[27,28] Local recurrence in the absence of a rising PSA may occur, so annual DRE and radiologic studies based on patient-reported symptoms are also performed. In the metastatic setting, treatments that target AR signaling and traditional chemotherapies have been shown to increase survival. Clinical efficacy is measured using imaging studies, symptom scores, weight changes, analgesic requirements, and PSA response. When using PSA as a surrogate for disease progression, it is important to consider not only the degree of elevation, but also the velocity at which the marker changes. A rapid PSA velocity has been associated with an increased risk of all-cause mortality and should warrant consideration of therapeutic intervention. Monitoring for adverse effects is different for each treatment modality but is similarly important.[50] For oral agents, medication adherence is also an important monitoring parameter at each clinic visit.

Abbreviations Introduced in This Chapter

ADT	Androgen deprivation therapy
AR	Androgen receptor
BPH	Benign prostatic hyperplasia
CAB	Combined androgen blockade
CRPC	Castration-resistant prostate cancer
CT	Computed tomography
CYP	Cytochrome P450
DES	Diethylstilbestrol
DHT	Dihydrotestosterone
DRE	Digital rectal examination
EBRT	External beam radiation therapy
FDA	Food and Drug Administration
FSH	Follicle-stimulating hormone
GnRH	Gonadotropin-releasing hormone
Gy	Gray
LFT	Liver function test
LH	Luteinizing hormone
LHRH	Luteinizing hormone–releasing hormone
mCRPC	Metastatic castration-resistant prostate cancer
mCSPC	Metastatic castration-sensitive prostate cancer
nmCRPC	Nonmetastatic castration-resistant prostate cancer
PAP-GM-CSF	Prostatic acid phosphatase granulocyte-macrophage colony-stimulating factor
PARP	Poly(ADP-ribose) polymerase
PLND	Pelvic lymph node dissection
PSA	Prostate-specific antigen
RANK	Receptor activator of nuclear factor kappa-B
SNP	Single-nucleotide polymorphism
TRUS	Transrectal ultrasound

Melanoma

Chung-Shien Lee

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify the risk factors associated with skin cancer.
2. Devise a plan of lifestyle modifications for the prevention of skin cancer.
3. Discuss the importance of mutation testing in the therapy selection for melanoma treatment.
4. Explain the goals of therapy for the treatment of different nonmelanoma and melanoma stages.
5. Compare and contrast the available pharmacologic treatment options for nonmelanoma and melanoma skin cancer.
6. Suggest management strategies for patients experiencing adverse effects of pharmacologic therapy.

INTRODUCTION

Skin cancer is the most common malignancy in the United States with over 5 million new diagnoses reported in roughly 3 million individuals. Of these, more than 95% are diagnosed with nonmelanoma skin cancer (NMSC), while the rest of skin cancer diagnoses are accounted for by malignant melanoma (MM).[1,2] NMSC incidence increased 300% since 1994 and continues to rise due to increasing high-risk populations, such as organ transplant and photosensitizing medication users. NMSC consists of basal cell carcinomas (BCCs) and squamous cell carcinomas (SCCs), which originate in the basal cell layer and the hair follicle stem cells, respectively.[3] MM differs substantially from NMSC with regard to its metastatic potential, prognosis, and treatment options.

MALIGNANT MELANOMA

EPIDEMIOLOGY AND ETIOLOGY

MM is the most diagnosed malignancy in young adults and the fifth most frequently diagnosed cancer overall in the United States, representing approximately 5% of all cancer cases. Although accounting for less than 3% of the skin cancer diagnoses, MM is responsible for the majority of skin cancer deaths (75%).[1,4] With a median age at diagnosis of 65, approximately half of MM cases are diagnosed between ages 55 and 74. An estimated 106,110 new cases are predicted to occur in 2021.[5] However, these figures may underestimate MM, since many superficial and in situ melanomas are treated in outpatient settings and thus not included in the Surveillance, Epidemiology, and End Results (SEER) registry.

RISK FACTORS

MM risk factors include environmental and host factors. **KEY CONCEPT** Sun exposure and ultraviolet (UV)-based artificial tanning are the main environmental triggers for melanoma occurrence. Residing in sunnier climates closer to the equator with potential for chronic sun exposure also increases the risk of melanoma. While MM can occur in any ethnic group and also on less exposed areas of the body, individuals of fair complexion (fair hair and light-colored eyes) have an increased risk.[5] Furthermore, individuals with genetic susceptibility may develop exacerbated skin reactions to the sun or UV radiation (UVR), particularly UVB. While UVB exposure is a well-known risk factor, the most common genetic lesions induced by UVB are C to T conversions, while the most common melanoma associated mutations are BRAF V600E and NRAS Q61L, which are unlikely to be caused by UVB.[6] Recent evidence does supports a UVR-induced mutation mechanism for melanoma occurrence: the hot-spot mutations in *RAC1*, *STK19*, and *PPP6C*.[7]

Furthermore, well-documented UVR-induced *TP53* tumor suppressor gene mutations are responsible for ineffective DNA repair, resulting in apoptosis dysregulation, modified keratinocyte expansion, and initiation of skin cancer. Today, it is estimated that over two-thirds of MMs are attributable to UVR. Moreover, childhood severe sunburns were associated with twice the risk of developing melanoma.

Epidermal melanin acts as a sun protection factor in individuals with darker skin tones, providing an skin protection factor (SPF) of up to 13.4 in Black people.[8] Family history of MM in a first-degree relative is associated with twice the risk of MM. Benign melanocytic nevi (benign moles) are also consistently identified as a risk factor for MM development. The risk of developing MM is also higher in patients with a personal history of MM, NMSC, or dysplastic nevus syndrome.[9] Having five or more dysplastic nevi increases the risk of MM up to six times. A similarly increased risk was noted in cases with congenital melanocytic nevi (bigger than 20 cm diameter).[9] A set of host-related risk factors used in the assessment of MM risk is provided in Table 93–1.

PRIMARY PREVENTION OF SKIN CANCER

Educating patients to avoid excessive exposure to the sun is strongly supported by the American Academy of Dermatology, American Cancer Society, Environmental Protection Agency, and Centers for Disease Control and Prevention. These programs aim at increasing public awareness about the mutagenic effect of

Table 93–1

Host-Related Risk Factors for Melanoma Development

Demographics
- Gender: male
- Age: > 60 years

Skin Phenotype
- Fitzpatrick skin type: pale white skin, blue or green eyes, blond or red hair
- Tanning ability: tendency to sunburn
- Moles: increased count and size with atypical features and pattern

Medical History
- Sunburns: multiple with or without blistering
- Cancer: benign or malign skin cancer or childhood cancers
- Impaired immune system: hematopoietic or solid organ transplant, HIV/AIDS
- Genodermatoses: Xeroderma pigmentosum

Genotype
- First-degree family history
- Susceptibility genes (*CDKN2A, CDK4, MC1R, BRCA2, BAP1*)

Data from Refs. [4,7].

UVR exposure and changing social norms related to sun protection and tanning, with an ultimate goal to decrease skin cancer incidence and deaths related to MM. The following strategies are recommended to minimize UVR exposure:

- Seek shade when outdoors, especially between 10 AM and 2 PM
- Wear hats that provide shade for the face, ears, and neck
- Wear protective clothing made of tightly woven fabric that covers the arms, legs, and torso. Clothing with a UV protection factor (UPF) can provide additional protection.
- Avoid sunbathing and indoor tanning
- Take extra caution when located near water, sand, and snow
- Use UV (radiation) A/B (UVA/B) waterproof sunscreen with a minimum SPF of 15; reapply every 2 hours if sweating or swimming
- If wearing makeup, use one with SPF

Patient Encounter 1, Part 1

A 70-year-old Black man presents to his dermatologist with complaints of pain surrounding a mole located on his right arm.

History: He has been getting his moles checked regularly since it was recommended by his primary doctor 20 years ago. He has four prominent moles located on his chest, neck, and face, but eight larger, notable nevi on his back and arms. Over the last month, he noted a new discolored mole appearing on his right arm with increasing pain.

The man reports that he loves hiking and the outdoors and hikes usually from 10 AM to 4 PM at least three times weekly for the last 40 years. He does not use sunscreen stating he does not like the way it feels.

What risk factors does this patient have for the development of melanoma?

Are any of his risk factors modifiable?

What concerns exist with the development of a new mole at his age?

Sunscreen should not be the sole means of skin cancer prevention. While sunscreen reduces risk of actinic keratosis (AK) and SCC, there is limited evidence to support efficacy in preventing BCC and MM. In addition, sun protection options can lead to or increase the risk of vitamin D deficiency or insufficiency.[10] Therefore, vitamin D level should be closely monitored, and appropriate supplementation is recommended for blood levels lower than 30 ng/dL.

SECONDARY PREVENTION OF SKIN CANCER

Secondary prevention of skin cancer involves detection of premalignant cancers for early intervention to increase the likelihood of cure. Regular screening by skin self-examination or total skin examination performed by healthcare providers consistently identifies smaller and thinner lesions in high-risk patients.[11] To date, the recommendations for melanoma screening are conflicting because there are no randomized, controlled, prospective melanoma trials demonstrating that routine screening reduces mortality. However, evidence exists that clinical whole-body skin examination reduces the incidence of thick melanomas, a pathological feature known to be directly associated with MM mortality.

PATHOPHYSIOLOGY

Although the vast majority of MMs originate from the skin, few may arise from various other epithelial tissues, including the conjunctiva, oral mucosa, penis, urethra, and others. The malignant process originates in abnormal melanocyte proliferation as a consequence of genetic susceptibility and/or exposure to a mutagenic agent, such as UVB. Interestingly, in individuals with high genetic susceptibility, MM may develop on body sites only exposed intermittently, such as the trunk or thighs, while it requires significant chronic UVB exposure of areas such as face and neck, in individuals with low genetic susceptibility.[12] Thus, location alone may be an indication regarding the occurrence mechanism.

Genetic Basis of Melanoma Development

MM has the highest prevalence among the cancers caused by chronic mutagenic exposure.[6] Approximately half of MM cases carry *BRAF V600* mutations and are expected to derive a clinical benefit from BRAF inhibitors.[7] BRAF is a serine/threonine protein kinase that is a member of the RAF kinase family, which is a part of the RAF/MEK/ERK serine threonine cascade (also known as ERK/MAP kinase pathway or "classical" mitogen-activated protein kinase [MAPK] pathway).[12] Mutations in *BRAF* activate the ERK/MAP pathway and thus trigger melanocyte proliferation and clonal expansion. *BRAF*-mutant melanomas tend to occur in individuals younger than 55 years with Fitzpatrick skin types I or II, lower cumulative UV exposure, and on skin areas intermittently exposed to the sun. Out of more than 50 *BRAF* mutations described, the valine to glutamic acid (*BRAF V600E*) substitution accounts for over 75% of all *BRAF* mutations.[13] BRAF and MEK kinase inhibitors are the mainstay treatment for *BRAF* mutation–positive metastatic melanoma.

Since melanocytes' differentiation, proliferation, and survival regulation is controlled by a microphthalmia-associated transcription factor (MITF), its alteration impacts antiapoptotic proteins leading to uncontrolled growth and tumor development. Other relevant MM mutations include *CDKN2A* and *PTEN* deletions, as well as *RAC1*, *NRAS*, *PPP6C*, and *STK19*.

Table 93–2

Characteristics of Different Types of Skin Cancer

	Malignant Melanoma				Nonmelanoma Skin Cancer	
	Superficial Spreading	Nodular	Lentigo Maligna	Acral Lentiginous	Basal Cell Carcinoma	Squamous Cell Carcinoma
Frequency	70%	10%–15%	10%	< 10%	75%	20%
Location	Female: Head, neck, legs Male: Trunk	Trunk, head, neck	Face, head, neck	Palms, soles, nail beds	Head and neck	Face, hands, forearms
Age	Fifth decade	Seventh decade	Eighth decade	Sixth decade	> 40 years	> 40 years
Ethnicity	White	White	White	Ethnic groups of color	Nonspecific	African Americans
Prognosis	Good	Very poor	Good	Very poor	Good	Poor
Clinical features	Long horizontal growth phase (5–7 years)	Very aggressive, deeply invasive, no identifiable horizontal growth phase	Long horizontal growth phase (10 years) In situ, only 5% are malignant	Aggressive, rapid progression from horizontal to vertical growth	Rarely metastasizes Several subtypes	Metastasizes Premalignant and in situ variants

Data from Refs. 8 and 10.

Clinical Presentation and Diagnosis

There are four major subtypes of cutaneous MM: superficial spreading, nodular, lentigo maligna melanoma, and acral lentiginous (Table 93–2). They each vary in clinical and growth characteristics.[14]

SEER data show that 83% of diagnosed MM are locally confined, 9% are diagnosed after the cancer has spread regionally, 4% are diagnosed with distant metastasis, and the remaining 4% cannot be staged.[5] KEY CONCEPT Once skin cancer is diagnosed, the disease is staged to determine confinement to the original location or any spread to other sites, such as the lymph nodes, liver, brain, lungs, or bone. The purpose of staging is to determine prognosis and aid in clinical decision-making. As with most solid tumors, the tumor, node, metastasis (TNM) classification is used to stage MM. Staging of solid tumors is described in Chapter 88.

Determination of lymph node involvement is an independent prognostic factor, and it provides therapy selection guidance. MM patients whose peripheral and deep margin status after biopsy indicate a risk for disease spread to the lymph nodes also receive a sentinel lymph node (SLN) biopsy. An SLN is the nearest lymph node to receive lymph draining directly from the biopsied tumor.

Other prognostic factors considered for assessment include primary tumor thickness (Figure 93–1), the presence of ulceration at the primary site, local mitotic activity, the presence of tumor-infiltrating lymphocytes (TIL), and gender.[15,16] Male sex is associated with poor prognosis and adverse outcome in MM.[17]

Skin Examination

The ABCDE acronym is a helpful mnemonic for recognizing the signs and symptoms of early MM (Figure 93–2).[9] Not all MMs, including nodular melanoma, have all ABCDE characteristics; thus, ABCDE is not meant to provide a comprehensive evaluation of all MM features. The characteristics for each of the letters are described in Figure 93–2. It should be noted that the evolution of a lesion is one of the most important warning signs in the assessment for MM.

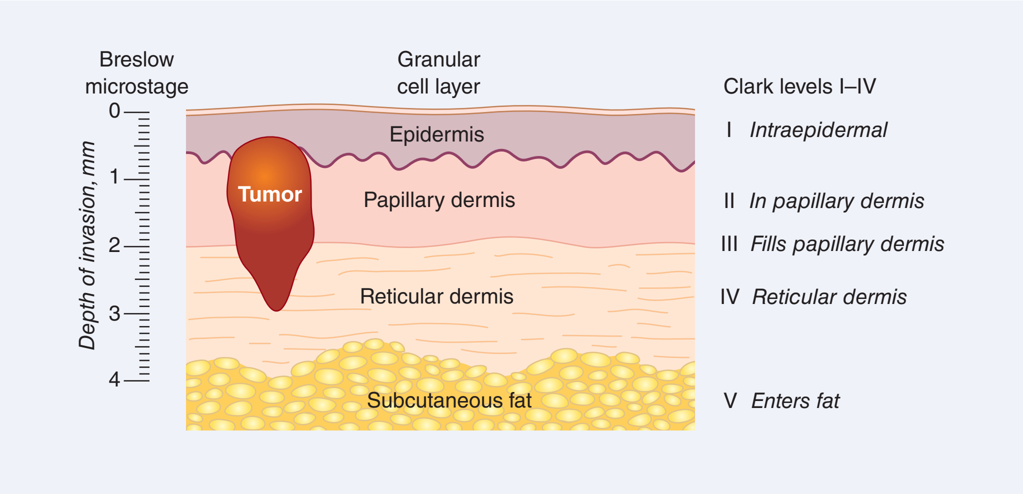

FIGURE 93–1. Skin anatomy: Breslow microstaging and Clark levels. Clark level refers to the level of penetration into the dermis. Breslow classification measures tumor thickness in millimeters from the epidermis to the deepest depth of penetration into the dermis. (From Langley RGB, Barnhill RL, Mihm Jr, MC, et al. Neoplasms: cutaneous melanoma. In: Freedberg IM, Eisen AZ, Wolff K, et al., eds. Fitzpatrick's Dermatology in General Medicine, 6th ed. New York, NY: McGraw-Hill; 2003:938.)

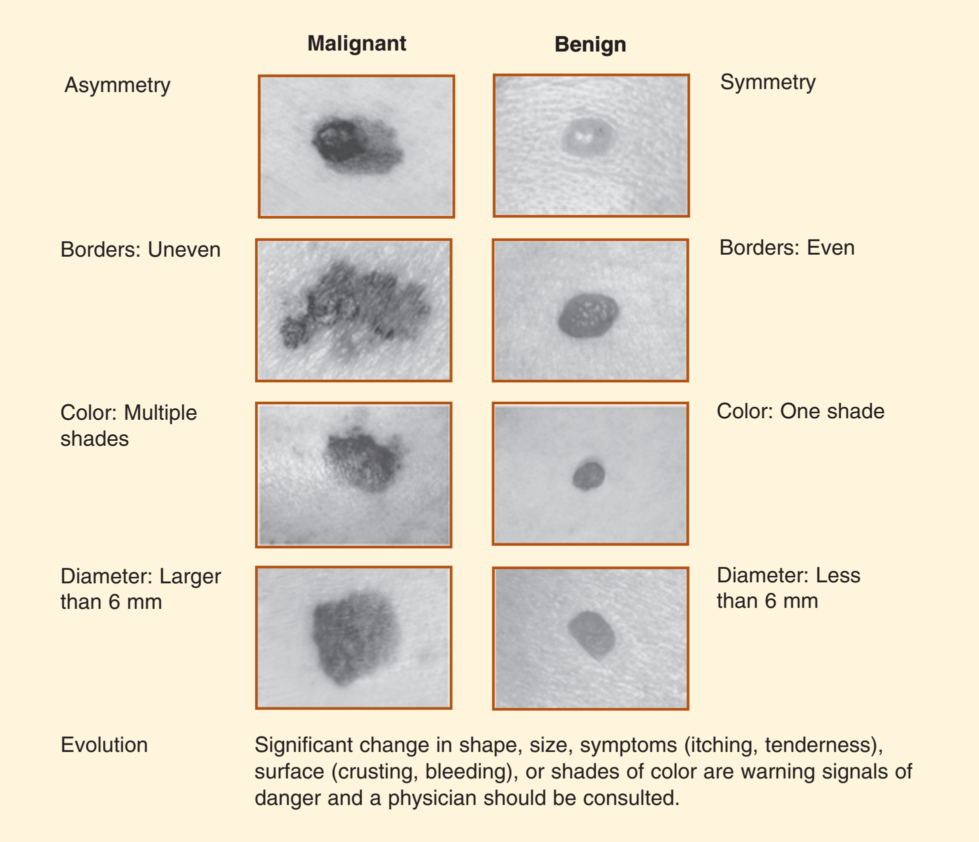

Malignant
Benign
Asymmetry
Symmetry
Borders: Uneven
Borders: Even
Color: Multiple shades
Color: One shade
Diameter: Larger than 6 mm
Diameter: Less than 6 mm
Evolution
Significant change in shape, size, symptoms (itching, tenderness), surface (crusting, bleeding), or shades of color are warning signals of danger and a physician should be consulted.

FIGURE 93–2. ABCDE features of early melanoma. (Images courtesy of the Skin Cancer Foundation, New York, www.skincancer.org.)

Clinical Presentation of MM

MM lesions may occur anywhere on the body. The most common sites are the head, neck, trunk, and extremities. MM appearance such as thickness, the presence, or the absence of ulceration, as well as any lesion characteristic change, are important risk indicators. Abnormal presentations of a mole or lesion indicate the need for further assessment.

- **Asymmetry:** Half the lesion does not mirror the other half
- **Border:** Sharp, ragged, uneven, and irregular borders
- **Color:** Multiple shades of brown, black, red, blue, or gray
- **Diameter:** Larger than 6 mm or the size of a pencil head eraser
- **Evolving:** Significant change in shape, size, symptoms, surface, or shades of color

Other signs and symptoms to monitor for in a lesion, in addition to ABCDE, include the following:

- Sudden or continuous lesion enlargement or elevation
- Changes in the skin surrounding the nevus
- Presence of redness, swelling, itching, tenderness, or pain
- Friability of the lesion with bleeding or oozing (ie, ulceration) is an indicator of poor outcomes

Less Common Sites and Manifestations of MM

It is important to examine these sites for "hidden" MM.

- Nail bed
- Mucosal tissue
- Scalp
- Eye

In the nail bed, a black streak or wide variegated brown streak, elevation of nail bed, darker skin surrounding the nail, deformed or destroyed nail, or an increasing nail streak size over time are all possible manifestations of MM.

Diagnostic Tests

- Dermoscopy
- Biopsy

Staging Tests (Depending on Patient's Presentation)

- Baseline chest radiography
- Tumor cell mitotic rate
- LDH level
- CT of chest, abdomen, pelvis
- SLN biopsy: **KEY CONCEPT** The status of the SLN involvement is one of the most powerful independent prognostic factors predicting survival. It also provides the clinician with guidance for therapy decisions and accurate staging.
- PET
- MRI

TREATMENT

Early diagnosis of MM is a key to improved prognosis. New-onset melanoma cases usually present with a recent history of unusual melanocyte growth or an area of irritation around a patch of melanocyte cells. Alternately, the melanoma may have gone undetected for years. In either of the two possibilities, a definitive diagnosis of any suspected cutaneous malignancy should be confirmed by a biopsy before treatment is initiated. MM treatment options depend on the tumor size, location, pathological features, and stage. The age of the patient and medical history, including the results of genotyping studies, all play a role in the clinical decision-making. The considered options include surgery, radiation, **immunotherapy**, **targeted therapy**, biochemotherapy, a combination of immunotherapy and chemotherapy, and a combination of immunotherapy and targeted therapy.

Desired Outcomes

The primary goal in MM treatment is the eradication of the tumor, lowering the risk of recurrence and metastasis. Secondary goals of MM therapy include preserving skin tissue integrity, appearance, and function while providing optimal cosmetic outcomes. For localized MM (stages I and IIA), surgical resection of the tumor is curative. Thus, probability of cure may be considerably improved with early diagnosis. Patients with regional disease, however—stages IIB, IIC, and III—have a poorer prognosis, characterized by a higher chance for recurrence. In cases with regional disease, the goal of therapy is relapse prevention and maintenance of the quality of life. Finally, in melanoma patients with disseminated disease, cure or prevention of relapse have become somewhat achievable outcomes as a result of immune checkpoint inhibitors. Supportive care is essential for patients undergoing systemic treatment to optimize the quality of life.

Patient Encounter 1, Part 2

PMH: HTN since 20 years ago, type II diabetes since 15 years ago, and hypercholesterolemia since 15 years ago dysplastic nevus syndrome. Patient is currently being treated with azithromycin for an upper respiratory tract infection.

FH: Father had type II diabetes, hypercholesterolemia, gout, and hypertension. Mother had dysplastic nevus syndrome, but no melanoma and breast cancer.

SH: Patient is a retired office worker. Married with three adult children.

Examination: Reveals an asymmetrical new nevus of approximately 6 mm with irregular discolored borders and a lighter center on the right arm with no lesions noted.

Biopsy: Excisional biopsy of the right arm nevus reveals melanoma.

CT Scan: No distant metastases.

Laboratory Data: Normal.

He underwent wide surgical excision of the lesion with a 3-mm margin resection after lymphatic mapping with sentinel lymph node biopsy. Pathology revealed negative margins and two of three nodes positive for melanoma. His melanoma is diagnosed as a stage IIIB. Testing for BRAF mutation comes back negative. Lymphadenectomy of the right axilla has been performed as well.

Would surgical excision of the lesion be curative in this patient?

Could medications typically used to treat his current disease states increase his risk of developing melanoma?

Considering the patient has stage IIIB melanoma, what pharmacologic treatment would you recommend?

MM treatment outcomes largely depend on the clinical disease stage at the time of diagnosis. Based on the data published in the SEER Cancer Statistics Review, the 5-year survival rate for patients with localized MM is 99%, the rate decreases to 66% in cases with regional disease, and it drops below 27% in individuals diagnosed with distant disease. There has been tremendous improvement with distant disease. The 5-year survival rate was never greater than 20% prior to 2010 but is projected to top 40% in the near future.[5]

Nonpharmacologic Therapy

▶ *Surgery*

KEY CONCEPT The primary treatment modality for local/regional disease (stages I to III) is surgical excision of the tumor with lymphadenectomy in patients with positive SLN. The goals of surgical excision are to gain local control and achieve potential cure while minimizing morbidity. Achieving adequate surgical margins for the primary tumor is important in preventing local recurrence and improving the overall survival. The extent of the surgical margin is, generally, dictated by the tumor thickness, but also by the result of the SLN.[18] The most common first site of recurrence in primary melanoma after tumor excision is the lymph nodes. In patients with regional or distant melanoma, surgical excision provides temporary symptomatic relief. Individuals with regional disease presenting with a good performance status and less aggressive tumor biology may observe longer disease-free intervals after surgery; however, this is only possible if disease can be successfully contained within the anatomical region. By contrast, in patients with stage IV melanoma median 5-year survival rates range from 5% to 19% depending on the location and number of metastases.[19] Surgical resection of symptomatic or life-threatening brain lesions may be an option to reduce neurologic deficits, seizures, and intracranial hypertension in patients with MM disseminated to the brain.[18]

▶ *Radiation*

Radiation is rarely indicated for the treatment of primary melanoma. An exception is when surgical excision cannot be performed. Radiation treatment may be administered as adjuvant therapy in areas where complete excision of the tumor is difficult, such as the face, or may be employed in lymphatic areas when complete lymphadenectomy is not feasible. In cases with bone metastasis, radiation may be indicated as palliative therapy to decrease fracture risk, control spinal cord compression, and improve pain management.[20] Radiation may also be used for symptom control of central nervous system (CNS) metastases.[20]

Brain metastases, presenting as headaches and seizures, are common in advanced melanoma, between 10% and 40% of patients presenting with CNS disease and more than 50% developing CNS disease.[18,21] Historically, life expectancy ranged from 3 to 5 months after the development of brain metastasis, however, new treatment modalities have improved this to approximately 1 year.

Table 93–3

Systemic and Regional Therapy for Primary Melanoma and Metastatic Disease

	Stage II_B/II_C	Stage III (SLN+)	Stage III (Clinical Node+)	Stage III with Local Disease	Metastatic or Recurrent Disease
Ipilimumab[a]		X	X	X	X
Intralesional therapy T-VEC, BCG				X	X[b]
Isolated limb infusion/perfusion Melphalan				X	
Topical therapy Imiquimod				X	
Nivolumab		X	X	X	X
Pembrolizumab		X	X	X	X
Dabrafenib/trametinib (if BRAF V600 positive)		X	X	X	X
Vemurafenib/cobimetinib (if BRAF V600 positive)					X
Encorafenib/binimetinib (if BRAF V600 positive)					X

[a] If prior exposure to anti-PD-1 therapy.

[b] T-VEC.

BCG, Bacille Calmette–Guerin; SLN+, sentinel lymph node positive; T-VEC, talimogene laherparepvec.

Pharmacologic Therapy

Historical approaches to the management of melanoma included cytotoxic chemotherapy, immunotherapy with interleukin-2 (IL-2) or interferon-α-2b, and combinations of these therapies. However, BRAF inhibitors and immunotherapy with checkpoint inhibitors and ipilimumab have replaced these earlier strategies.[22-28]

▶ *Intralesional Therapy*

Intralesional therapies have been evaluated in melanomas since the 1960s and are generally associated with high response rates locally, but a lack of systemic activity.

Talimogene Laherparepvec (T-VEC)

Talimogene laherparepvec (T-VEC) is the first FDA-approved intralesional therapy for the treatment of unresectable, recurrent melanoma. It is a genetically modified herpes simplex oncolytic virus therapy administered directly into the cutaneous or subcutaneous melanoma lesions or into the visible or palpable nodal lesions.[24] The virus is designed to selectively multiply in the tumor cells. Its mechanism of action is still being investigated; however, the therapeutic benefit likely occurs via the involvement of the tumor antigens that are thought to serve as an autologous vaccine. The drug is delivered by injection using a "fanning" technique (one needle entry with multiple directions of administration), starting with the largest tumor. Grade 3 or 4 treatment-related adverse events were reported in 7.3% of the treated patients and included nausea and vomiting, abdominal pain, fever and chills, and wound infection.[24] Of the treated patients, 12.2% achieved a complete response. T-VEC use is usually limited to patients with unresectable disease with limited visceral involvement.

Patient Encounter 1, Part 3

This patient presents 3 weeks later after the initiation of nivolumab, 1 week prior to the next dose with diarrhea. He reports having three bowel movements a day for the last several days.

What, if any, changes would be appropriate to this patient's stage IIIB melanoma treatment?

What additional laboratory tests are appropriate to request at this time?

Bacille Calmette–Guerin

An attenuated strain of *Mycobacterium bovis* originally developed as a vaccine against tuberculosis, the Bacille Calmette–Guerin is sometimes used for intralesional administration to stimulate an immune response toward the injected site; however, adverse effects, including anaphylaxis, preclude its routine use.[29]

▶ *Immune Checkpoint Inhibitors*

T-cell activation involves two different signals that enhance the host immune response:[30]

- T-cell receptor binding to the major histocompatibility complex presented peptide located on the antigen-presenting cell (APC)
- T-cell costimulatory receptor (CD28) interaction with a costimulatory ligand (B7) on the APC surface

The cytotoxic T lymphocyte (CTL)–associated protein 4 (CTLA-4) is expressed in CD4+ and CD8+ T cells and regulatory T cells. CTLA-4 is a member of the immunoglobulin (Ig) superfamily that migrates to the T-cell surface upon its activation allowing binding with a higher affinity to the B7 ligand than CD28. This results in a downregulation on the immune response; in other words, CTLA-4 acts as a "brake" on the activation of the immune system.[30]

Ipilimumab As a human monoclonal CTLA-4-specific antibody, ipilimumab has a high affinity for CTLA-4 and prevents CTLA-4 from binding to B7, an action that inhibits the downregulation of the immune response.[30] Ipilimumab increases proliferation of activated T cells and increases the interactions between T cells and cancer cells. Ipilimumab is FDA approved for unresectable metastatic melanoma, either as a single agent or in combination with nivolumab, as well as the adjuvant treatment of stage III melanoma.[31,32] T-cell activation can lead to severe adverse events, such as enterocolitis, hepatitis, dermatitis, including toxic epidermal necrolysis, neuropathy, and endocrinopathy. Corticosteroids are the treatment of choice for ipilimumab-induced adverse events. The administration of steroids to treat the side effects does not affect ipilimumab's effectiveness. Interestingly, there may be a correlation between immune-related adverse events and treatment success.[33]

Nivolumab Many tumor cells express programmed death-ligand 1 (PD-L1), a surface marker that can interact with programmed death-1 (PD-1) receptor on T cells and B cells, thus diminishing the body's immune response. Nivolumab is an IgG4 human antibody that targets PD-1, hence preventing the PD-L1 binding to PD-1. As a result, T cells remain active to mount an immune response against the tumor. Nivolumab is indicated for both unresectable and metastatic MM as a single agent or in combination with ipilimumab, after progression on ipilimumab or a BRAF and MEK inhibitor (if *BRAF V600* mutation positive). It is also indicated in the adjuvant setting for stage III, resected melanoma. Patients with confirmed unresectable, previously treated, stage III or IV melanoma without *BRAF* mutation receiving nivolumab had a 72.9% overall survival rate at 1 year, as compared to 42.1% in the dacarbazine group.[34] Common side effects may include rash, pruritus, peripheral edema, fatigue, diarrhea, and cough. Rare but serious adverse events may include ventricular arrhythmia, infection, colitis, hepatotoxicity, and neuropathy.

Pembrolizumab This checkpoint inhibitor is an anti-PD-1 humanized antibody. The FDA-approved indication includes unresectable and metastatic MM following ipilimumab and, if *BRAF* V600 mutation positive, a BRAF and MEK inhibitor. Pembrolizumab is also indicated in the adjuvant setting for stage III completely resected melanoma. In patients with unresectable stage III or IV melanoma who received up to one previous therapy, 2-year survival rates were 55%.[35] Common side effects may include arthralgia and constipation/diarrhea, while rare but serious adverse events may include colitis, hepatitis, pancreatitis, pneumonitis, and hypophysitis. According to a study comparing the incidence of immune-related adverse events associated with ipilimumab versus pembrolizumab, significantly fewer gastrointestinal and dermatological adverse events were reported with pembrolizumab use; however, a higher incidence of thyroiditis and pneumonitis was noted.[36]

Atezolizumab Atezolizumab is a humanized anti-PD-L1 antibody that was FDA-approved for BRAF V600 mutation–positive unresectable or metastatic melanoma in combination with cobimetinib and vemurafenib. This is the first approved checkpoint inhibitor and targeted therapy combination. The addition of atezolizumab to a BRAF and MEK inhibitor compared to a BRAF and MEK inhibitor demonstrated a 22% reduction in the risk of progression. Common side effects, when given in combination with a BRAF and MEK inhibitor, may include rash, musculoskeletal pain, fatigue, hepatotoxicity, pyrexia, nausea, pruritus, edema, stomatitis, hypothyroidism, and photosensitivity reaction. Rare but serious adverse events may include colitis, hepatitis, pneumonitis, and hypophysitis.

▶ *RAF-MEK-ERK Pathway Targeted Therapy for BRAF-Mutant MM*

KEY CONCEPT BRAF/MEK combined regimens provide a considerable therapeutic advantage against occurrence of melanoma resistance in patients with metastatic melanoma.

Vemurafenib/Cobimetinib The serine/threonine kinase B-Raf (BRAF) is an intermediary in the signal transduction through the RAF-MEK-ERK MAPK pathway. BRAF activation is followed downstream by the activation of ERK with increase in the cyclin D1 levels, and enhanced cellular proliferation.[37] The proto-oncogene B-Raf *(BRAF)* is mutated in approximately 50% of melanomas, and over 75% of these mutations are *BRAF V600E.*[13] Vemurafenib is an oral serine/threonine kinase inhibitor that binds to the adenosine triphosphate binding domain of *BRAF* mutant; hence, the presence of the mutation is required for treatment effect.[38] Vemurafenib selectively targets the *BRAF V600E* isoform and has an indication for the treatment of unresectable stage IIIC or metastatic melanoma that is *BRAF V600* mutation positive. **KEY CONCEPT** Although vemurafenib was initially approved as a single agent, resistance develops rapidly via activation of MEK, and the combination of vemurafenib and the MEK inhibitor cobimetinib demonstrates improved progression-free survival compared to vemurafenib alone in patients with *BRAF-mutant* metastatic melanoma[39] (see Figure 93–3 and Table 93–4 for dosing recommendations).

Common side effects associated with vemurafenib may include photosensitivity, rash, arthralgia, and alopecia. Rare but serious side effects may include QT interval prolongation, hand–foot syndrome, vision changes, and SCC, although the latter can be excised without discontinuation of the agent.[37] Vemurafenib is metabolized by CYP3A4 and thus may interact with its inducers or inhibitors. It may increase the serum concentration of substrates of CYP1A2 and 2D6. It may decrease the serum concentration of substrates of CYP3A4.

Cobimetinib commonly causes photosensitivity, diarrhea, nausea, pyrexia, elevations in liver function tests (LFTs), as well as electrolyte abnormalities. Decreases in ejection fraction and hypertension can occur in up to 20% of the patients. Rare but serious adverse effects include bleeding and secondary neoplasms, including squamous and basal cell skin cancer and melanoma. Cobimetinib is metabolized by CYP3A4 and thus may interact with its inducers or inhibitors.

Dabrafenib/Trametinib Similar to vemurafenib, dabrafenib is a selective inhibitor of BRAF V600E kinase. While it is approved as both monotherapy for unresectable and metastatic MM with *BRAF V600E* mutation and combination therapy with trametinib for unresectable and metastatic MM with *BRAF V600E* or *V600K* mutation, the drugs are used almost exclusively in combination, as the combination has demonstrated superior efficacy than either drug administered as a single agent. The combination also significantly reduces the risk of recurrence of melanoma in completely resected patients with stage III melanoma when compared to placebo.[40, 41] Common side effects with dabrafenib include hypoglycemia, arthralgia, hand–foot syndrome, pyrexia, and neutropenia, while rare but serious adverse events may include QT prolongation, serious febrile reactions, uveitis, iritis, and SCC. Similar to vemurafenib, SCC can be excised without discontinuing dabrafenib. Dabrafenib is metabolized by CYP3A4 and 2C8 and thus may interact with its inducers or inhibitors. It may decrease the serum concentration of substrates of CYP3A4 and 2C9.

Trametinib is a MEK-1 and MEK-2 kinase inhibitor targeting MAPK pathway downstream of BRAF. The drug is approved as

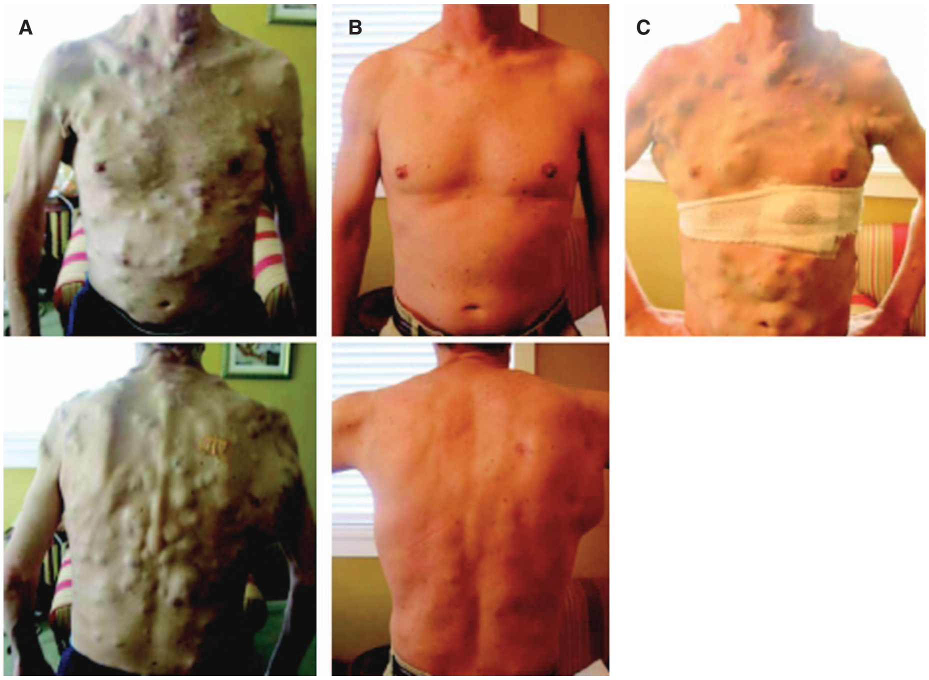

FIGURE 93–3. RAF inhibition resistance in melanoma. A 38-year-old man with BRAF-mutant melanoma. **A:** Before initiation of RAF inhibitor. **B:** After 15 weeks of therapy with an RAF inhibitor. **C:** After relapse, after 23 weeks of therapy. (Reproduced with permission from the Journal of Clinical Oncology. Wagle N, Emery E, Berger MF, et al. Dissecting therapeutic resistance to RAF inhibition in melanoma by tumor genomic profiling. J Clin Oncol. 2011;29(22):3085–3096.)

monotherapy or in combination with dabrafenib for *BRAF V600E* or V600K mutation–positive unresectable and metastatic melanoma, although currently only used in combination. Common side effects with trametinib include dry skin, diarrhea, and nail changes, while rare but serious adverse events may include vision changes and rhabdomyolysis.

Encorafenib/Binimetinib Encorafenib is a selective inhibitor of BRAF V600E kinase approved for unresectable and metastatic MM with *BRAF V600E* or *V600K* mutation only in combination with binimetinib. Similar to cobimetinib and trametinib, binimetinib is a MEK-1 and MEK-2 kinase inhibitor. The combination has prolonged survival compared to single-agent BRAF inhibitors. Common side effects with encorafenib and binimetinib include fatigue, nausea, vomiting, abdominal pain, and arthralgia, while rare but serious adverse events may include vision changes and QT prolongation.

The combination of a BRAF and MEK inhibitor has shown to be superior to monotherapy but has demonstrated a different side-effect profile. Combination treatments were associated with higher rates of flu-like symptoms, such as pyrexia and chills, and reduced ejection fraction. BRAF inhibitor monotherapy was associated with higher rates of musculoskeletal complaints, alopecia, hand–foot syndrome and skin toxicities, particularly keratoacanthoma, and cutaneous SCC. Severe toxicity was similar with combination treatment compared to the BRAF inhibitor monotherapy treatment.

OUTCOME EVALUATION

When evaluating MM therapy outcomes, refer to the primary and secondary goals of the respective MM stage, treatment selection, and case-related particularities, such as cosmetic considerations. Always evaluate the awareness and approach to avoid sun or UVR exposure, including compliance with regular total-body skin self-examination, regardless of disease stage and implemented treatment. Advise for appropriate changes if needed.

For localized disease:

- Evaluate skin integrity after tumor resection, appearance, and function.
- Assess the quality of life after surgery and whether any skin graft–related complication has been reported.
- Verify patient and family understanding regarding recurrence prevention.

For regional disease:

- Assess skin appearance and recovery after radiation therapy, as well as the quality of life and motor function recovery after lymphadenectomy.
- Evaluate effectiveness of any anticancer treatment.
- Review the relevant labs and make necessary treatment changes.
- Review treatment adverse events and the appropriateness of their management.
- Discuss treatment alternatives and options for recurrence prevention.

For disseminated disease:

- Identify patients' and their family goals and their compatibility with the observed treatment outcomes.
- Review the relevant labs and evaluate the effectiveness of palliative treatment.
- Assess chronic therapy side effects and evaluate the appropriateness of adverse event reporting and management.
- Assess patients' psychological, physical, and social functioning.

- Evaluate the use of current resources, such as the hospital's social service department or the American Cancer Society for assistance in dealing with the disease emotionally. Recommend attending support group meetings or talking to a counselor if or before they become overwhelmed with the diagnosis.

Table 93–4

Melanoma Treatment Dosing Recommendations[a]

Intralesional Therapy

Talimogene laherparepvec: 4 × 10^6 PFUs in ≤ 4 mL injected by intralesional fanning; inject 4 × 10^8 PFUs in ≤ 4 mL injected by intralesional fanning after 3 weeks, and biweekly thereafter for up to 24 doses

Immune Checkpoint Inhibitors

Ipilimumab: 3 mg/kg IV (over 90 minutes) every 3 weeks ×4 doses; permanently discontinue if not completed within 16 weeks[e]

Nivolumab: 240 mg IV (over 30 minutes) every 2 weeks or 480 mg IV (30 minutes) every 4 weeks until[c,d,e]

1 mg/kg IV (over 30 minutes) every 3 weeks × 4 doses (in combination with ipillmumab), then 240 mg every 2 weeks or 480 mg every 4 weeks[c,d,e]

Pembrolizumab: 200 mg IV (over 30 minutes) every 3 weeks or 400 mg IV (over 30 minutes) every 6 weeks[c,d,e]

Atezolizumab: 240 mg IV (over 1 hour) every 2 weeks until[c,d,e,f]

RAF-MEK-ERK Pathway Inhibitors

Vemurafenib: 960 mg orally every 12 hours[b,d]
Dabrafenib: 150 mg orally every 12 hours[d,g]
Trametinib: 2 mg orally once daily[d,g]
Cobimetinib: 60 mg orally once daily, days 1–21 of each 28-day cycle
Encorafenib: 450 mg orally once daily[d]
Binimetinib: 45 mg orally every 12 hours[d]

Chemotherapy

Dacarbazine: 250 mg/m^2/day IV, days 1–5, every 21 days[h]
Temozolomide: 150–200 mg/m^2 orally × 5 days, every 4 weeks
Vinblastine: 2 mg/m^2 days 1–4 and 22–25 of 6-week cycle
Cisplatin: 75 mg/m^2 IV day 1 with temozolomide 200 mg/m^2 orally × 5 days, cycled every 4 weeks
Carboplatin: target AUC 6 days, 1 of a 21-day cycle
Carmustine: 150 mg/m^2 IV day 1 with cisplatin 25 mg/m^2 IV days 1–3; repeat cycle with dacarbazine and cisplatin every 21 days; repeat cycle of carmustine every 42 days

[a] Refer to clinical trials to determine the specific dose based on the regimen the patient is receiving.

[b] Caution in severe renal or hepatic impairment; no dose adjustment needed for mild-to-moderate impairment.

[c] Baseline renal, liver, and thyroid function required; monitor periodically during treatment.

[d] Continue regimen until disease progression or unacceptable toxicity occurs.

[e] No formal studies have been done to assess cytochrome P450 interactions.[32]

[f] If the first infusion is tolerated, all subsequent infusions may be delivered over 30 minutes.

[g] Take on empty stomach.

[h] Inactive until metabolized by the liver; it requires reasonably good liver function.

IV, intravenous; SC, subcutaneous.

PATIENT CARE PROCESS

Refer to the section at the end of the chapter for the patient care process recommended for both MM and NMSC care.

KERATINOCYTE CARCINOMA

EPIDEMIOLOGY AND ETIOLOGY

Also known as NMSC, keratinocyte carcinoma[42] accounts for the vast majority of all newly diagnosed cancers each year. BCC is the most common form of keratinocyte carcinoma followed by the SCC as the second most common in the United States (see Table 93–2).

The true prevalence of keratinocyte carcinoma may be underestimated due to its treatment in outpatient settings, without formal reporting to cancer registries. Yet, understanding its incidence is critical to designing treatment strategies and providing proper resource allocation for its prevention.[43] The number of individuals with at least one NMSC procedure in the Medicare fee-for-service database increased by over 14% between 2006 and 2012. Although, BCC was previously reported as the most common form of NMSC, comprising 75% of the NMSC, the most recent study indicates a 50:50 ratio of BCC to SCC diagnosed in a Medicare population.[43] The majority of NMSCs are curable, and the mortality rate is low, however not negligible; cure rates approach 98%, and the overall 5-year survival rate is considerably greater than 95%. Metastasis occurs in less than 0.1% of BCCs compared to 3.6% of SCCs. Roughly 75% of all keratinocyte carcinoma deaths are attributed to SCC.[44] Keratinocyte carcinoma is associated with considerable morbidity related to functional and cosmetic deformity. In addition, it is an economic burden; the associated costs for NMSC treatment reaching $4.8 billion between 2007 and 2011, nearly double as compared to NMSC expenditure between 2002 and 2006. Importantly, both these figures exceed the costs of MM expenditure for the corresponding time frame.[45]

RISK FACTORS

The risk of developing keratinocyte carcinoma is multifactorial. Skin phenotype plays a similar role as in the MM development; individuals with pale skin, blue or green eyes, and blond or red hair are at risk of developing NMSC as well. A tendency to sunburn or an increased cumulative lifetime UVR exposure, particularly UVB due to its penetrability and higher energy, leads to biologically damaging effects, including direct DNA damage, signaling receptor-mediated pathways activation, and reactive oxygen species (ROS) formation.[3] Greater cumulative lifetime sun exposure is associated with a higher risk of developing SCC, but intermittent and childhood sun exposure correlates more with BCC. Individuals with a keratinocyte carcinoma have a 10-fold increased risk of developing subsequent skin cancer as compared to the general population.[46]

The vast majority of BCC cases are sporadic, although a small number occur in patients with Gorlin syndrome, an autosomal dominant disorder caused by mutations in the *PTCH1* gene. Additionally, up to 70% of patients with sporadic BCC have a mutation in the *PTCH1* gene.[46] By contrast, individuals with previous SCC are more likely to acquire additional SCC and, potentially, melanoma.[3] SCC has been reported to occur 100 folds more often in organ transplant recipients as compared to the general public, possibly due to the immunosuppressive therapy requirements in transplant patients.

Although responsible for a smaller number of keratinocyte carcinomas, arsenic has been shown to promote the expression of

Table 93–5

Photosensitizing Drugs

Antidepressants: citalopram, bupropion, fluoxetine
Glucose-lowering meds: glimepiride, glyburide, glipizide
Immunosuppressants: methotrexate, cyclosporine
Antibiotics: azithromycin, doxycycline, sulfonamides, ketoconazole, voriconazole, griseofulvin, trimethoprim
Insomnia/seizure/anxiety meds: alprazolam, quetiapine, zolpidem, valproic acid, gabapentin
Antiarrhythmics: amiodarone
Other: estrogens, cholesterol-lowering meds, NSAIDs, isotretinoin, vitamin A, St. John's wort
Antihypertensives: lisinopril, labetalol, hydralazine, diuretics

SCC-related keratins possibly by epigenetic modifications. Other reported offenders linked to the occurrence of NMSCs include photosensitizing drugs (Table 93–5), human papilloma virus and smoking, with the latter being reported rather in association with SCC than BCC.[47]

PATHOPHYSIOLOGY

NMSCs arise from epidermal keratinocytes and involve primarily squamous cells and basal cells of the epidermis and dermis skin layers. BCCs arise from interfollicular basal cells or keratinocytes in hair follicles or sebaceous glands.[47] Among them, AKs are the most common premalignant lesions. Incidence of AKs is primarily driven by increased cumulative UVR exposure. It is estimated that up to 16% of the AKs will progress to SCC, while approximately a quarter will undergo regression within a year.[47]

CLINICAL PRESENTATION AND DIAGNOSIS

BCC is characterized as *circumscribed* or *diffuse*, and within these two groups, it is further classified according to the type, degree of differentiation, and depth of invasion. The circumscribed types include nodular BCC, adenoid BCC, fibroepithelioma, and basosquamous or metatypical carcinoma. The diffuse BCC types are plaque-like with horizontal spread and poorly differentiated margins and include the superficial BCC, the morpheaform BCC, and the micronodular BCC.

Nodular BCC is the most common type of BCC followed by superficial BCC. The morpheaform BCC is the most aggressive subtype, while superficial BCC is the least.[13] BCC has indolent growth characteristics with a very low metastatic and mortality rate.[48] Paradoxically, BCCs can cause extensive local destruction and significant disfigurement. Approximately 80% of BCCs occur on the head and neck. Superficial BCC occurs predominantly on the trunk. Early-stage BCC is usually small, translucent, or pearly with raised telangiectatic edges.[48] BCC may also appear as raised, yellowish-reddish lesions with a border resembling a string of pearls and telangiectasia. Dermatoscopy may distinguish between a benign and malignant lesion; however, clinical examination is usually sufficient for the diagnosis of BCC. Depending on the size of the tumor, subtype, and treatment planned, a biopsy may be needed.

SCC usually presents on sun-exposed sites because of UVR damage to the skin. Unlike BCC, SCCs are preceded by premalignant lesions such as dysplastic leukoplakia (DL), AK, or SCC in situ (Bowen disease).[48] DL appears as a thickened skin formed in response to trauma or benign human papilloma virus infections. Its occurrence in other locations, such as the oral mucosa, may be due to chronic exposure to chewing tobacco. AK presents as a small papule on areas of sun damage to the skin. The rate of AK progression to SCC is 1% to 10% in 10 years and may be higher if a patient has more than five AKs.[48] Patients with a Bowen lesion present with slowly enlarging erythematous scaly or crusted plaques and have a 3% to 5% risk of progressing to SCC. A typical SCC lesion has an adherent crust and ill-defined edges; the first sign of malignant SCC is the induration of the lesion. The rate of metastasis for SCC is 2% to 6% and may be as high as 10% to 14% in high-risk sites such as the ear and lip and 30% in the genital area.[49] If progressing to metastasis, this may occur 1 to 2 years after the diagnosis of the primary SCC with 80% of metastasis involving the regional lymph nodes.

Keratinocyte carcinoma staging follows the TNM staging system recommended by the American Joint Committee on Cancer, based on tumor size, lymph node involvement, and dissemination. It is seldom done for patients with BCC because nodal

Patient Encounter 2, Part 1

A 43-year-old woman presents to her dermatologist with a raised lesion located in front of her right ear. She states that it got enlarged over the last few months.

History: The lesion began as a "reddish spot" nearly 2 years ago, then has raised, becoming gradually enlarged and more noticeable over the last 4 months.

The woman reports being a frequent tanning bed user due to her pale complexion but uses sunscreen regularly while outside, especially when vacationing on the beach. However, she does not typically reapply sunscreen on her face due to her makeup.

What are some characteristics that differentiate BCC from SCC?

What counseling points can be provided concerning the use of sunscreen or UV protective sprays on the head and face?

Patient Encounter 2, Part 2

PMH: The patient is 3 years status post renal transplantation.

FH: Father has HTN, diabetes, and atherosclerosis. Mother has osteoporosis and breast cancer.

Examination: Reveals a round, flesh-colored, waxy papule 0.4 cm in diameter positioned 1 cm from the tragus of the right ear with a pearly appearance and slight pigmentation in the center. Two irregular blood vessels are visible.

Which type of NMSC is most likely present on this patient?

What risk factors, if any, does this patient have for recurrence of the disease or progression to metastases?

What is the most appropriate initial treatment option for this patient?

and visceral metastases are rare for this type of keratinocyte carcinoma.[48] Dermatoscopy may be employed for such instances, a technique involving the use of epiluminescence or surface microscopy. This test is usually performed by the dermatologist and may improve early detection.

TREATMENT

KEY CONCEPT In patients diagnosed with BCC and SCC, the primary goal of therapy is cure and prevention of recurrence. Despite the low mortality rate, the tissue destruction, functional impairment, and disfigurement associated with keratinocyte carcinoma diagnosis and treatment are very significant issues. Therefore, secondary goals of therapy for NMSC are preservation of function and restoration of cosmesis. The treatment options for NMSC involve surgery, pharmacologic therapy, or a combination thereof. Treatment selection depends on factors such as tumor size, the site of the lesion, patient comorbidities, histologic particularities, and clinical nature of the cancer.

Nonpharmacologic Therapy

▶ *Surgery*

Surgery is the primary treatment modality for all patients diagnosed with keratinocyte carcinomas. Full-thickness ablative procedure in the form of surgical excision of the tumor along with a margin of normal tissue surrounding the tumor is the preferred method for high-risk tumors. Obtaining negative surgical margins is critical for cure and decreasing the risk of tumor recurrence. A margin of 4 to 5 mm in the case of well-defined keratinocyte carcinomas ensures peripheral clearance in 95% of cases. Depending on the tumor size, degree of differentiation, and invasion of surrounding structures, larger margins of resection may be necessary.[48] The two most common surgical techniques used are electrodessication and curettage (ED&C) and Mohs micrographic surgery (MMS). The indications of each of these procedures are described below.

Low-risk tumors defined as small, well differentiated, and slow growing can be treated with superficial ablative techniques, including ED&C and cryotherapy.[48] ED&C is a simple, cost-effective technique that uses repeated cycles of using a curette to cut through malignant tissue followed by the application of high voltage low current to the skin causing drying or desiccation of the tissue. ED&C is indicated for well-defined superficial lesions that are not located in areas with increased risk for metastasis. The disadvantage of this technique is that histologic confirmation of complete tumor removal is not possible.[44] This procedure is not recommended for the treatment of recurrent disease, tumors of the face, and high-risk tumors.[44]

For high-risk NMSC or tumors located in cosmetically or anatomically sensitive areas, MMS is the procedure of choice. The goal of this therapy is complete removal of the cancer with preservation of as much surrounding normal tissue as possible. MMS involves careful dissection, staining of frozen sections, and anatomic mapping of the tumor specimen. Sections are assessed immediately under the microscope by the surgeon, and the process is repeated until a tumor-free margin is attained. MMS cures 93% of primary NMSC and 90% to 94% of recurrent disease compared with 92% and 77% cure rate with standard excision for primary and recurrent disease, respectively.[50] Cure rates for all modalities decrease with the presence of high-risk features but are still superior to MMS.[50]

Cryotherapy is a procedure used primarily for smaller, low-risk keratinocyte carcinomas with clearly defined margins. It involves delivering liquid nitrogen at subzero temperatures as a spray or with a supercooled metal probe to destroy the malignant tissue in a single cycle or multiple cycles.[44] This technique can achieve comparable results to conventional surgery for well-differentiated, not too large, superficial tumors in older patients with BCC.[44] The procedure is contraindicated in the hair-bearing scalp, upper lip, and distal portion of lower leg because of delayed healing and high rates of recurrence.[44]

▶ *Radiation*

Radiation is not standard therapy for the treatment of keratinocyte carcinomas; however, there are circumstances in which radiation may be preferred. It may be offered to patients in whom surgery is not possible because the tumor is inoperable or surgery would lead to unacceptable cosmetic or functional impairment.[50] Radiation to the lip, ear, and nasal entrance for SCC may provide the best cosmetic and functional result. On the other hand, some patients may develop dyspigmentation, radio-dystrophy, or telangiectasia at the irradiated site, resulting in poorer cosmetic outcomes. It should be used with caution in patients younger than 65 years because latent NMSC can develop after 15 to 20 years of radiation exposure.[48]

▶ *Photodynamic Therapy*

Photodynamic therapy (PDT) involves the topical application of a photosensitizing light-activated agent that causes tumor cell damage and death. The photosensitizer is converted to protoporphyrin IX after it is preferentially taken up by active tumor cells. Damage to cell membranes, organelles, and surrounding vasculature occurs when protoporphyrin IX is activated after exposure to a light source. Protoporphyrin IX has absorption bands at 408, 510, 543, 583, and 633 nm; therefore, blue light (corresponding to 408-nm band) and red light (corresponding to 633-nm band) are the most commonly used light wavelengths.[47] Blue light is used for superficial lesions because of its shorter wavelength and it does not penetrate the skin as well as red light.[44]

δ-Aminolevulinic acid (ALA) and methyl aminolevulinate (MAL) are two photosensitizing agents that have FDA approval for the treatment of AK, but MAL is no longer produced in the United States (Table 93–6 for dosing).[28] PDT has also been shown to be effective in the treatment of SCC in situ, but it is not indicated for SCC because of its extensive invasiveness and metastatic potential.[28]

Pharmacologic Therapy

▶ *Fluorouracil*

Nonsurgical treatment is used frequently for superficial keratinocyte carcinomas. Topical 5-fluorouracil has been used for the treatment of dermatologic disorders for approximately 45 years, and it has FDA approval for the treatment of AK and superficial BCC. Fluorouracil is available as both solution and cream with strengths ranging from 1% to 5%. There is also a microsphere-encapsulated 0.5% cream that has reduced systemic absorption with enhanced skin retention to reduce systemic side effects. The microsphere formulation is applied only once a day, providing patient preference and convenience over the twice daily application with the other formulations. The FDA has approved 2% to 5% cream or solution and 0.5% microsphere formulation for AK. For superficial BCC, only the 5% strength is FDA approved for this indication. The most common side effects with topical fluorouracil are expected to occur within the initial 5 to 10 days of treatment and include possible erythema, irritation, burning sensation, pruritus, and pain along with hypo- or hyperpigmentation. Patients may also experience inflammatory reactions that include crusting, edema, and oozing. The fluorouracil strength or frequency of application may be reduced if severe reactions occur. Topical steroids may be used concurrently with fluorouracil cream and for 1 to 2 weeks after treatment.[28] Caution should be used in administering fluorouracil to patients with dihydropyrimidine dehydrogenase deficiency, an enzyme critical in the metabolism of fluorouracil, because increased toxicity may occur.

Table 93–6

Topical Therapy for Actinic Keratosis

Methyl Aminolevulinate Hydrochloride
Apply maximum 1 g topically on lesion(s) for one PDT session, followed by occlusive dressing for 2.5–4 hours, then red light illumination for 7–10 minutes. Two PDT sessions 1 week apart are required.

Aminolevulinic Acid
Apply topically to lesion(s) and let dry, then repeat once; rinse and pat dry after 14–18 hours, then expose to blue light photodynamic therapy illuminator; may repeat after 8 weeks. Cover and protect lesions with light-opaque material for 40 hours; sunscreen is ineffective.

Topical Fluorouracil
Apply 2% or 5% solution or cream topically twice daily over lesions for 2–6 weeks or apply 0.5% microsphere formulation once daily for up to 4 weeks.

Imiquimod
Apply topical formulation at bedtime daily 5 × per week for 6 weeks; leave on skin for 8 hours

The doses presented here are general. Clinicians should refer to reference materials to determine the specific dose based on the regimen the patient is receiving.

PDT, photodynamic therapy.

► *Imiquimod*

This therapy option works by stimulating innate and cell-mediated immune responses. It is FDA approved for the treatment of AK and superficial BCC of the trunk, neck, or extremities when surgery may not be employed and follow-up is assured. Imiquimod has been shown to have complete clearing of AK in 50% of patients and partial clearing in 75% of patients with AK compared with 5% for those treated with placebo. Cure rates for imiquimod 5% in patients with superficial BCC are greater than 90%. The response rate is much lower for nodular BCC at 75%; therefore, it should be used in these patients only if they are not able to undergo surgery, radiation, or cryotherapy, and the tumor is small and in a low-risk area. Imiquimod is not recommended for the treatment of invasive SCC, but data for SCC in situ showed a 93% cure rate; thus, it may be considered for this patient population.

Imiquimod is available in 3.75% strength, which may be applied daily on larger areas of skin, the balding scalp, or the full face, and 5% strength, which may be used on areas of skin that are 25 cm^2 or smaller (see **Table 93–6**). Imiquimod should be applied before bedtime and left on the skin for 6 to 10 hours. The most common side effects with imiquimod involve the area of application and present as erythema, pruritus, a burning or stinging sensation, and tenderness. Less commonly, hypopigmentation, fever, diarrhea, and fatigue may also occur. Temporary discontinuation of imiquimod and application of topical steroids may be necessary to alleviate the irritation symptoms. Imiquimod may be resumed at a decreased frequency after the symptoms have resolved.[28]

► *Vismodegib*

Genetic alterations in the Hedgehog signaling pathway cause loss of function of *PTCH1*, which normally inhibits the signaling activity of Smoothened (SMO), a transmembrane protein involved in Hedgehog signal transduction. This first-in-class oral inhibitor of the Hedgehog signaling pathway is a small molecule that binds to and inhibits SMO. Vismodegib is approved by the FDA for the treatment of adult locally advanced or metastatic BCC that has recurred following surgery or has not been a candidate for surgery or radiation at a dose of 150 mg by mouth daily. Common side effects with vismodegib include muscle spasms, dysgeusia, hair loss, fatigue, nausea, and vomiting, while rare but serious adverse events may include severe cutaneous reactions and embryo–fetal toxicity. Patients should not donate blood or blood products while receiving vismodegib and for 24 months after the final dose of vismodegib.

► *Sonidegib*

Sonidegib is also an inhibitor of the Hedgehog signaling pathway. It is FDA approved for the treatment of adult patients with locally advanced (BCC) that has recurred following surgery or radiation therapy, or those who are not candidates for surgery or radiation therapy at a dose of 200 mg by mouth daily on an empty stomach. Common side effects with sonidegib include muscle spasms, dysgeusia, hair loss, fatigue, nausea, vomiting, and elevated serum creatinine, while rare but serious adverse events may include rhabdomyolysis and embryo–fetal toxicity. Patients should not donate blood or blood products while receiving sonidegib and for 20 months after the final dose of sonidegib.

OUTCOME EVALUATION

- Evaluate awareness and approach to avoid sun exposure and perform total-body skin self-examination.
- Assess treatment tolerance at every visit and ensure proper administration technique with topical treatments, such as fluorouracil or imiquimod: cleaning of treatment area before application, lesion area coverage with a 1-cm margin, and use of gloves, as well as handwashing after application.
- Assess side effects' management such as pain, itching, and inflammation and reinforce the need for dermatologist, consult if worsening.
- Verify the presence of the *PTCH1* mutation before initiation of oral SMO inhibitor treatment and assess compliance.

ACKNOWLEDGMENTS

The author and editors wish to acknowledge and thank Drs. Alice C. Ceacareanu and Treavor T. Riley, the authors of this chapter in the fifth edition of this book.

Patient Care Process

Collect Information:

- Review current diagnosis with emphasis on skin cancer clinical signs (ABCDE)
- Obtain demographic information, family history, geographical location, and any specific lifestyle habit that may constitute risk factors
- Document medical and treatment history with emphasis on immune conditions, immunodeficiencies and immunosuppressive therapies, and medications associated with increased sun-related sensitivity (see Table 93–8)
- Any allergy or history of intolerance to biologics
- Understand cosmetic expectations and identify socioeconomic factors that may interfere with access to treatment and regular follow-ups

Assess the Information:

- Assess the possible causes of tumor occurrence (medical history, lifestyle, treatment, etc)
- Evaluate current performance status and assess other medications compliance
- Evaluate any treatment history that may (have) cause(d) photosensitivity
- Determine eligibility for immunotherapy and other current pharmacotherapy options
- Assess BRAF genotype status
- Review relevant laboratory tests (eg, electrolytes, liver panel, renal panel)
- Identify any predisposition to expected adverse events

Develop a Care Plan:

- Identify any contraindication for specific treatment options and select the best therapy
- Identify counseling points relevant to the patient and family
- Design a medication administration plan
- Design an adverse event monitoring and management plan

Implement the Care Plan:

- Educate the patient about the current options, explain the therapy selection, medication administration, common adverse events, and reporting and management
- Review the patient's practices for skin cancer prevention
- Discuss the importance of medication adherence and lifestyle modifications to reduce skin cancer risk
- Address any patient concern about treatment outcomes
- Determine access to healthcare insurance and ensure smooth delivery of the treatment
- Assess patient expectations and verify their understanding regarding the course of treatment

Follow-up: Monitor and Evaluate:

- Evaluate how tumor resection affected the skin integrity, appearance, function, and the quality of life postoperative
- Assess skin recovery after radiation
- Verify patient and family understanding regarding subsequent prevention and systematic skin self-examination
- Review reported adverse events and appropriateness of their management
- Discuss treatment alternatives and options for recurrence prevention
- Review the appropriateness of lab monitoring for the ongoing treatment plan
- Address any palliative care symptom and assess patients' psychological, physical, and social functioning

Abbreviations Introduced in This Chapter

AK	Actinic keratosis
ALA	δ-Aminolevulinic acid
APC	Antigen-presenting cell
BCC	Basal cell carcinoma
BRAF	Proto-oncogene B-Raf
CDKN2A	Cyclin-dependent kinase inhibitor-2A
CNS	Central nervous system
CTL	Cytotoxic T lymphocyte
CTLA-4	Cytotoxic T lymphocyte–associated protein 4
CYP	Cytochrome P450
DL	Dysplastic leukoplakia
ED&C	Electrodessication and curettage
ERK	Extracellular signal–regulated kinase
HD	High dose
IFN	Interferon-α-2b
Ig	Immunoglobulin
IL-2	Interleukin-2
LFT	Liver function test
MAL	Methyl aminolevulinate
MAL–PDT	Methyl aminolevulinate–photodynamic therapy
MAP	Microtubule-associated protein
MAPK	Mitogen-activated protein kinase
MEK	MAPK/ERK kinases
MITF	Microphthalmia-associated transcription factor
MM	Malignant melanoma
MMS	Mohs micrographic surgery
NMSC	Nonmelanoma skin cancer
NRAS	Neuroblastoma RAS viral oncogene
PD-1	Programmed death-1
PD-L1	Programmed death-ligand 1
PDT	Photodynamic therapy
PPP6C	Protein phosphatase 6 catalytic subunit
PTCH1	Patch homolog-1
PTEN	Phosphatase and tensin homolog
RAC-1	Ras-related protein C3 botulinum toxin substrate 1 precursor
RAF	Proto-oncogene Raf-1
RECIST	Response Evaluation Criteria in Solid Tumors
REMS	Risk Evaluation and Mitigation Strategy
SCC	Squamous cell carcinoma
SEER	Surveillance, Epidemiology, and End Results
SLN	Sentinel lymph node

SMO	Smoothened
SPF	Skin protection factor
SRS	Stereotactic radiosurgery
STK19	Serine/threonine-protein kinase 19
TIL	Tumor-infiltrating lymphocytes
TNM	Tumor, node, metastasis
UVA/B	Ultraviolet (radiation) A/B
UVR	Ultraviolet radiation
WBRT	Whole-brain radiation therapy
XP	Xeroderma pigmentosum

Ovarian Cancer

Judith A. Smith

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Demonstrate understanding of the etiology and risk factors associated with the development of ovarian cancer.
2. Justify the risk and benefits of the surgical and chemoprevention options available for decreasing the potential risk of developing ovarian cancer.
3. Interpret and understand the utility of the screening tests and serologic markers for diagnosing ovarian cancer.
4. Distinguish the nonspecific physical signs and symptoms of ovarian cancer.
5. Recommend the appropriate surgical and chemotherapy treatment options for newly diagnosed, persistent, and recurrent ovarian cancer patients.
6. Discuss the role of first-line maintenance treatment for improving overall survival for ovarian cancer patients.
7. Compare and contrast chemotherapy options for women with recurrent platinum-resistant ovarian cancer.

INTRODUCTION

Ovarian cancer is relatively uncommon but is the most incurable of the gynecologic cancers. Ovarian cancer is often denoted as the "silent killer." KEY CONCEPT The primary reason for the high mortality rate associated with ovarian cancer is the nonspecific symptoms and difficulty for early detection or screening that result in patients presenting with advanced disease. The majority of ovarian cancers are of epithelial origin. Each time **ovulation** occurs, the epithelium of the ovary is broken followed by occurrence of cell repair. The incessant ovulation hypothesis proposes that the increasing number of times the ovary epithelium undergoes cell repair is associated with the increasing risk of mutations and ultimately ovarian cancer. Although the majority of patients will achieve a complete response (CR) to primary surgery and chemotherapy, disease recurs in more than 50% of patients in the first 2 years after completion of primary treatment. KEY CONCEPT Ovarian cancers often cause metastasis via the lymphatic and blood systems to the liver and/or lungs. Common complications of advanced and progressive ovarian cancer include **ascites** and small bowel obstruction (SBO), which often are associated with the end of life.

EPIDEMIOLOGY AND ETIOLOGY

In 2021, there were an estimated 21,410 new cases of ovarian cancer diagnosed with an associated 13,770 deaths.[1] Ovarian cancer remains the number one gynecologic killer and the fifth leading cause of cancer-related death in women. Despite great efforts and extensive research, addition of new agents and routes of administration, there has been little change in the mortality rate associated with ovarian cancer over the past six decades. Again, this high mortality rate associated with ovarian cancer can be attributed to its insidious onset of nonspecific symptoms, resulting in the majority of patients not presenting until the cancer has progressed to stages III to IV disease.

As with many other disease states, a significant risk factor associated with ovarian cancer is aging. Risk of ovarian cancer increases from age 40 to 79 years, with the mean age at diagnosis being 63 years and the majority of women being diagnosed between 55 and 64 years.[2]

Ovarian cancer is a sporadic disease; fewer than 10% of ovarian cancers can be attributed to heredity. KEY CONCEPT The majority of cases of ovarian cancer occur sporadically, making it difficult to screen and prevent. Although hereditary cancer accounts for fewer than 10% of all ovarian cancer cases, when there is a family history, it appears to be an important risk factor in the development of ovarian cancer in some patients.[3] If one family member has a diagnosis of ovarian cancer, the associated risk is about 9%, but this risk increases to greater than 50% if there are two or more first-degree relatives (ie, mother and sister) with a diagnosis of ovarian cancer or multiple cases of ovarian and breast cancer.[3] Both breast cancer activator gene 1 (*BRCA1*) and gene 2 (*BRCA2*) mutations have been associated with ovarian cancer. However, *BRCA1* is more prevalent, being associated with 90% of hereditary and 10% of sporadic cases of ovarian cancer.[3] Hereditary breast and ovarian cancer (HBOC) syndrome is one of the two different forms of hereditary ovarian cancer and is associated with germline mutations in *BRCA1* and *BRCA2*.[3-5] The hereditary **nonpolyposis** colorectal cancer (HNPCC) or Lynch syndrome is a familial syndrome with germline mutations causing defects in enzymes involved in DNA mismatch repair, which has been associated with up to 12% of hereditary ovarian cancer cases.[4]

Patient Encounter 1

The patient is a 63-year-old active, nonobese woman, who has been in good health up until recently (last 3 months) when she started to feel frequent reflux, bloating, and fatigue. During a weekly virtual visit with her granddaughter during the corona virus pandemic, she mentioned to her daughter that she had been lots of reflux lately despite use of OTC antacid medications. The following monday she saw her primary care provider who recommended dietary modifications and to complete a 6-week trial of prescription proton pump inhibitor. Six weeks later, her reflux persisted and now she felt more bloated and has started to have difficulty with bowel movements too. Her primary care provider ordered endoscopic exam and an abdominal CT scan that came back positive for bilateral ovarian masses including a 10-cm noncystic mass on left ovary and 6-cm mass on the right ovary, and omentumal thickening. Of note, she has been married for 29 years with only three sexual partners in her lifetime. They have three daughters and a son who are all grown adults. Her first menses was when she was 10 years old and menopause was at age 59 years. She has had infrequent alcohol on social occasions only and denies any tobacco use.

Based on the results from the abdominal CT scan, what laboratory tests are needed and what type of specialist should she be referred to complete her workup?

In the context of this patient, discuss why ovarian cancer is often denoted the "silent killer" and what needs to be done for earlier diagnosis of ovarian cancer.

Discuss the type of surgery recommended and outcome goal for this surgery.

Although it is not clearly defined, hormones and reproductive history are associated with the risk of developing ovarian cancer. **Nulliparity**, infertility, early menarche, or late menopause is associated with an increased risk of ovarian cancer.[6]

Ovarian cancer is associated with certain dietary and environmental factors as well. A diet that is high in galactose and animal fat and meat increases the risk of ovarian cancer, whereas a vegetable-rich diet is suggested to decrease the risk.[6,7]

Screening and Prevention

▶ *Screening*

Currently, there is no standard effective screening tool that is adequately specific or sensitive for early detection.[8]

Pelvic examinations are effective for detecting obvious tumors present with a sensitivity of 67% for detecting all tumors; however, minimal or microscopic disease cannot be detected on physical examination.[9] Pelvic examinations are noninvasive and well accepted, but they do not usually detect ovarian cancer until it is in advanced stage. Transvaginal ultrasound (TVUS) is a component of current screening practices. Typically, it is used in combination with cancer antigen-125 (CA-125) or could be used as a single modality. TVUS releases sonic sound waves that create an image of the ovary to evaluate the size and shape and detect the presence of cystic or solid masses. Limitations of this technique are lack of specificity and an inability to detect peritoneal cancer or cancer in normal size ovaries.[2,9] Most prevention clinics use this multimodality approach to screen high-risk women and recommend yearly ultrasound in combination with CA-125 blood test every 6 months.

Patient Encounter 2

A 45-year-old woman diagnosed with stage IIa adenocarcinoma of the ovary with positive *BRCA1* mutation status post optimal debulking surgery completed six cycles of paclitaxel 175 mg/m^2 IV plus carboplatin AUC 5 IV plus bevacizumab 15 mg/kg that was given once every 21 days. Her CT scan findings suggest no detectable disease and CA-125 within the normal range (13 U/mL [13 kU/L]) upon completion of her chemotherapy. She feels great and has no obvious symptoms of ovarian cancer at this time.

Discuss the advantages and disadvantages of treatment options for maintenance treatment with PARP inhibitor versus bevacizumab versus the combination of both bevacizumab plus PARP inhibitor for this patient. Describe the role of second-look surgery for this patient.

Serum CA-125 is the most extensively evaluated tumor marker for ovarian cancer. **KEY CONCEPT** Because CA-125 is a nonspecific marker, it is not a standard recommendation for routine screening for prevention of ovarian cancer. Unfortunately, since CA-125 is nonspecific, elevated levels can be associated with a number of other gynecologic and GI-related diseases. CA-125 levels in a woman without ovarian cancer are static or tend to decrease over time, but levels associated with malignancy continue to rise.[9,10]

▶ *Prevention*

Ovulation is considered a hostile event to the ovarian epithelium, making it more susceptible to damage and cancer. Interventions or conditions that limit the number of ovulations in a woman's reproductive history, including **multiparity**, have a protective effect.

Chemoprevention Investigational chemoprevention strategies used for ovarian cancer include oral contraceptives (OCs), aspirin, nonsteroidal anti-inflammatory agents, and retinoids, although none of these is currently accepted as standard treatment for the prevention of ovarian cancer. The theory that OCs reduce the number of ovulatory events is a basic explanation of its protective effect. Recent studies have suggested that progestin-induced apoptosis of the ovarian epithelium is responsible for the chemopreventive effect of OCs. The theory is that cells that have genetic damage but are not yet neoplastic have an increased chance of undergoing apoptosis.[10,11] OCs decrease the relative risk to less than 0.4% in women who use OCs for longer than 10 years.[12] However, the maximum protective effect of OC use in women with *BRCA* mutations has been reported to be between 3 and 5 years.[12] At the same time, OC use has been associated with an increased risk of breast cancer.[11,13] Thus, women with a family history of breast cancer are not ideal candidates for this preventive measure.

Nonsteroidal anti-inflammatory agents, aspirin, and acetaminophen have been evaluated for preventing of different cancers, especially hereditary nonpolyposis colon cancer.[13] Although observational studies have linked these to a reduction of ovarian carcinoma risk, evidence is still lacking. Potential mechanisms include effects on normal ovulation shed and inhibition of ovulation.[13] Other pharmacologic interventions that have been suggested but are still being evaluated include vitamin A, lutein,

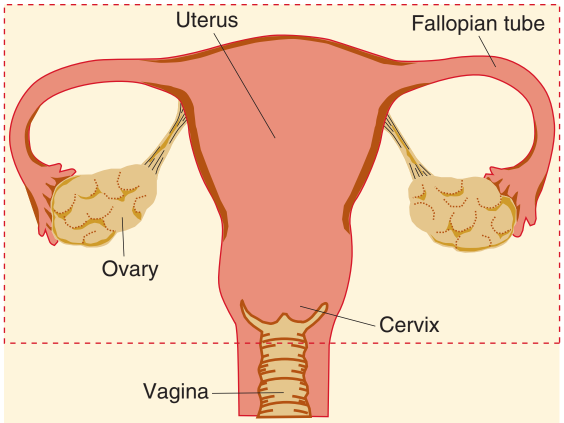

FIGURE 94–1. Diagram of female reproductive tract (uterus, fallopian tubes, ovaries, vagina). The *dashed line box* outlines what is removed during the total abdominal hysterectomy with bilateral salpingo-oophorectomy (TAH/BSO).

and other carotenoids.[14] The protective effect of these agents is associated with inhibition of cell growth as well as promotion of cellular differentiation.[14]

Prophylactic Surgery Surgical strategies are also used in the prevention of ovarian cancer. The goal is to remove healthy, at-risk organs and ultimately reduce the risk of developing cancer. These surgeries include prophylactic bilateral salpingo-oophorectomy (BSO) or tubal ligation (Figure 94–1).

Prophylactic oophorectomy should be considered in any woman with a high risk of developing ovarian cancer.[15,16] The criteria for defining high risk include any woman with two or more first-degree relatives with epithelial ovarian carcinoma; a family history of multiple occurrences of nonpolyposis colon cancer, endometrial cancer, and ovarian cancer; and a family history of multiple cases of breast and ovarian cancer.[17] Patients undergoing prophylactic oophorectomy need to be made aware that complete protection is not guaranteed.[17-19] Although a 67% reduction in risk has been shown, a potential 2% to 5% risk of peritoneal carcinomatosis remains.[18-20]

Tubal Ligation Tubal ligation is another procedure that has shown potential for risk reduction. However, it is not recommended as a sole procedure in prophylaxis. The protective effect may be attributable to limiting exposure of the ovary to environmental carcinogens. A case–control study conducted by Narod and colleagues[19] found that a history of tubal ligation in *BRCA*-positive women was associated with a statistically significant 63% reduction in risk.

Genetic Screening Genetic screening is recommended for all patients with new ovarian cancer diagnosis. Ovarian cancer has been associated with high prevalence of actionable pathogenic genetic variants.[4] Patients should be screened for genes such as *BRCA1* and *BRCA2* as well as other genes such as those associated with HNPCC or the HBOC syndrome.[3,21] Patient and family counseling and genetic counseling should be available for the patient and family to prepare and deal with the health and psychosocial implications of the genetic test results. Before performing genetic testing, the potential preventive options should be discussed, such as prophylactic BSO and/or total hysterectomy. Cancer risk and patient's health need to be balanced, but typically surgery can be held off until after the childbearing years.[20-22]

PATHOPHYSIOLOGY

The three current theories are the incessant ovulation hypothesis, the pituitary gonadotropin hypothesis, and the chronic inflammatory processes hypothesis.[2] The incessant ovulation hypothesis proposes that the pathogenesis of ovarian cancer is connected to continual ovulation. Ovulation is considered a "hostile" event to the ovaries, perhaps with not enough time for adequate repair. Each time ovulation occurs, the ovary epithelium is disrupted, and cell damage occurs. Thus, repeated ovulations may lead to a greater number of repairs of the ovarian epithelium and increase the possibility of aberrant repairs, mutation, and carcinogenesis.[2] The pituitary gonadotropin hypothesis associates the disease with elevations in gonadotropin and estrogen levels.[2] This leads to an increase in the number of follicles and, therefore, an increased risk of malignant changes. Finally, the chronic inflammatory processes may be involved with various environmental carcinogens to cause cancer.[2,13]

The three major pathologic categories of ovarian tumors include sex-cord stromal, germ cell, and epithelial. About 85% to 90% of ovarian cancers are of epithelial origin. Epithelial ovarian tumors are composed of cells that cover the surface of the ovary such as serous, mucinous, endometrioid, clear cell, and poorly differentiated adenocarcinomas. Germ-cell tumors involve the precursors of ova with the most common type being dysgerminoma, which are most commonly diagnosed in women younger than the age of 40 years and generally have a better prognosis.[2] Sex-cord stromal tumors are not only indolent tumors that produce excess estrogen and androgens but also have a better overall prognosis.[2] Although the histologic type of the tumor is not a significant prognostic factor, it is important to know the histopathologic grade with high-grade being more aggressive and low-grade slower growing. Similar to other solid tumors, clear-cell histology tends to be high grade and often chemotherapy-resistant. Undifferentiated tumors are associated with a poorer prognosis than lesions that are considered to be well or moderately differentiated.

TREATMENT

Desired Outcomes

Healthcare providers use a multimodality approach, including surgery and chemotherapy, in initial treatment of patients with ovarian cancer with a curative intent, or restoring a normal life span. **KEY CONCEPT** Although the majority of patients initially achieve a CR, disease will recur within the first 2 years in more than 50% of patients.[2,23] CR to treatment is defined as no evidence of disease can be detected by physical examination or diagnostic tests and patient has a normalized CA-125.

The stage of disease at the time of diagnosis is the most important prognostic factor affecting overall survival in ovarian cancer patients.[24] The estimated 5-year survival rates of patients with localized, regional, distant, and unstaged ovarian cancer are 92.1%, 73.2%, 28.3%, and 22.8%, respectively.[7] The histology of the disease is another predominant prognostic factor influencing treatment outcomes. Clear-cell and undifferentiated tumors do not respond as well to chemotherapy.[2] The extent of residual disease and tumor grade are also predictive of response to chemotherapy and overall survival.[2] There are other prognostic factors that may predict how well a patient will respond to adjuvant chemotherapy.

The treatment goals shift when a patient presents with recurrent ovarian cancer. The desired outcomes focus on relief of symptoms such as pain or discomfort from ascites, slowing disease progression, and prevention of serious complications such as

Clinical Presentation and Diagnosis of Ovarian Cancer

General

Ovarian cancer typically has delay in diagnosis due to the common nonspecific signs and symptoms often initially suggesting GI-related complications. By the time symptoms become unrelenting and bothersome, patients most likely have advanced stage disease.

Symptoms

Patients may experience episodes or persistent symptoms such as abdominal pain, constipation or diarrhea, flatulence, urinary frequency, or incontinence.

Signs

The degree of abdominal swelling secondary to fluid accumulation may present like "pregnant abdomen" and irregular vaginal bleeding.

Laboratory Test

- CA-125. The normal level is less than 35 U/mL (35 kU/L). Note: This test is associated with a lack of specificity. CA-125 can be elevated in a number of other states such as different phases of the menstrual cycle, endometriosis, and nongynecologic cancers. Therefore, it is important to rule out other cancers associated with the abdominal cavity.
- Carcinoembryonic antigen (CEA). CEA is a marker for colon cancer. A normal value is less than 3 ng/mL (3 mcg/L). However, this can also be elevated in serous papillary carcinomas of ovary.
- CA-19-9 is a marker for many GI tumors such as cholangiocarcinomas.

Chemistries with Liver Function Tests (LFTs)

- LFTs and serum creatinine might be suggestive of extent of disease. The majority of this information is needed to determine if the patient is a surgical candidate. Laboratory study results should be within normal limits.

Complete Blood Count (CBC)

- Abnormalities in CBC are not associated with ovarian cancer; however, this information is needed to determine if the patient is a surgical candidate. Laboratories should be within normal limits.

Other Diagnostic Tests

To characterize local disease, one or both of the following are completed:

- TVUS
- Abdominal ultrasound

To evaluate the extent of disease, only one of the following is completed:

- CT scan
- MRI
- PET scan

Chest X-ray is also often done as part of clearance for surgery.

Ovarian cancer is usually confined to the abdominal cavity, but spread can occur to the lung and liver and less commonly to the bone or brain. Disease is spread by direct extension, peritoneal seeding, lymphatic dissemination, or blood-borne metastasis. Lymphatic seeding is the most common pathway and frequently causes ascites.

SBO. When a patient relapses, the prognostic factors are similar as after initial surgery except that the amount of time that has lapsed since the completion of chemotherapy should be considered to determine if drug resistance is emerging in the tumor. Recurrent platinum-sensitive ovarian cancer patients generally have a better prognosis than platinum-resistant patients.

Nonpharmacologic Therapy

KEY CONCEPT Surgery is the primary treatment intervention for ovarian cancer.[25-27] A total hysterectomy with BSO (TH-BSO) (see Figure 94–1), omentumectomy, and lymphonectomy (or lymph node dissection) is the standard initial surgical treatment of ovarian cancer.[25] The objective of the surgery is to debulk the patient to less than 1 cm of residual disease remains. Residual disease less than 1 cm correlates with better CR rates to chemotherapy and better overall survival compared with patients with bulky residual disease (larger than 1 cm).[22-24] The size of residual tumor masses after primary surgery is found to be another important prognostic factor in patients with advanced ovarian cancer.[27]

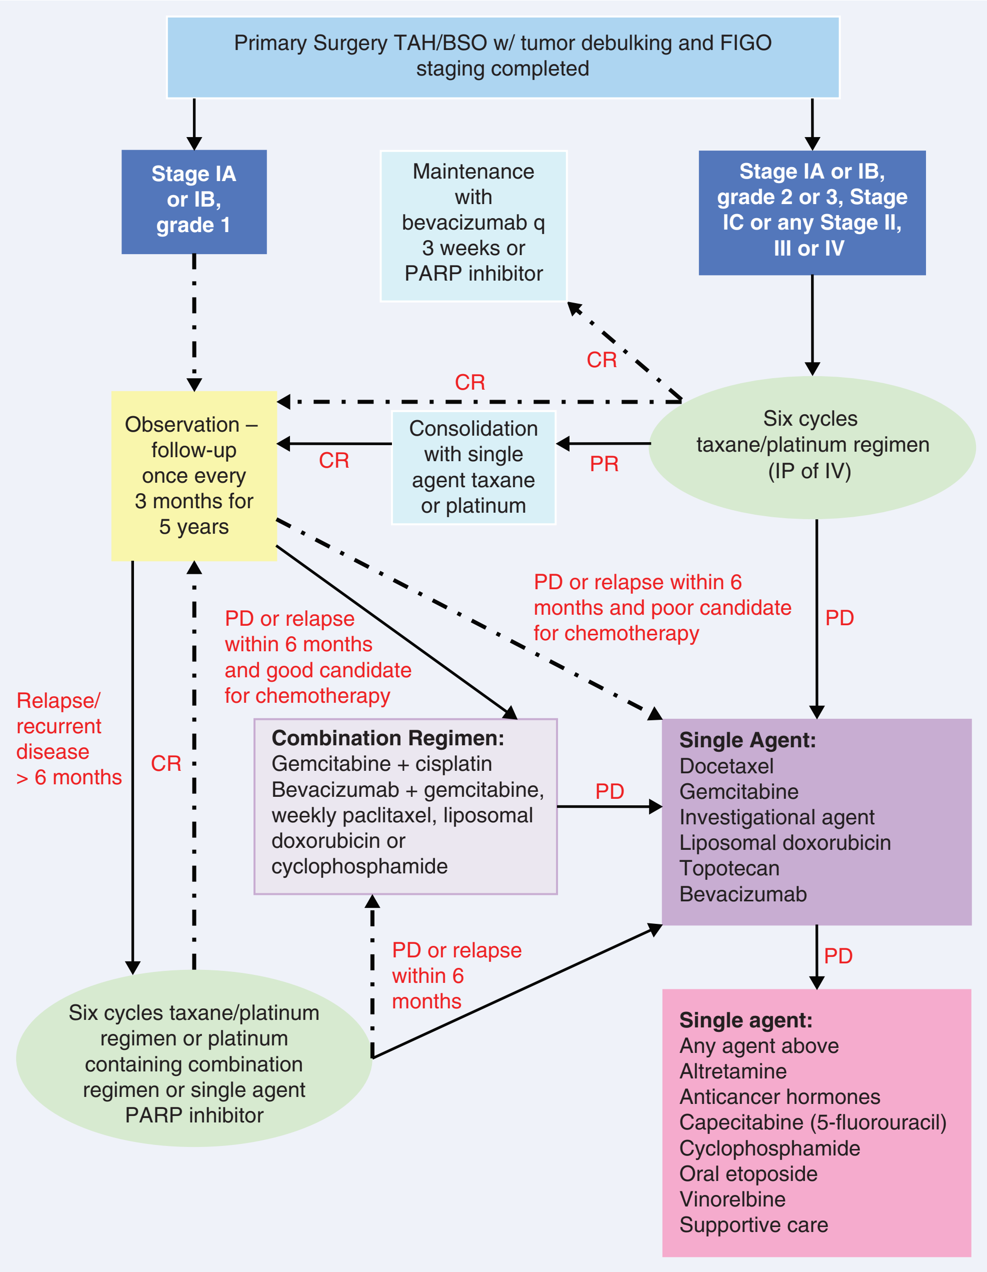
A thorough exploratory laparotomy is essential for the accurate staging of the patient.[22-24] **KEY CONCEPT** Ovarian cancer is staged surgically using the International Federation of Gynecology and Obstetrics (FIGO) staging algorithm. For certain patients with limited stage disease, surgery may be curative.

Other surgical procedures have been evaluated to improve overall survival. Debulking surgery is intended to relieve symptoms associated with complications such as SBO and help improve the patient's quality of life but does not have a curative intent. Interval debulking that is completed after two to three cycles of chemotherapy has not translated to an improved survival benefit. Often debated, the benefit of the "second-look laparotomy" to evaluate residual disease after the patient has completed chemotherapy remains controversial because it has been difficult to establish any impact on patients' overall survival. It has questionable benefit because although approximately 40% of patients with advanced disease have a negative second look, 50% still relapse.[2] The role of laparoscopic surgery is somewhat controversial for initial surgery but is more often considered in debulking of recurrent or advanced disease when the intent is palliative rather than curative.[23]

Pharmacologic Therapy

▶ *First-Line Chemotherapy*

KEY CONCEPT After initial surgery, the gold standard of care is six cycles of taxane/platinum-containing regimen for patients with advanced ovarian cancer.[25-27] Patients with limited disease, that is, stage IA, will have observation alone after surgery (Figure 94–2). The majority of patients will receive adjuvant chemotherapy within 3 to 4 weeks after surgery. Most often, paclitaxel is the taxane agent used in combination with carboplatin as the preferred platinum agent.[25-27] Depending on patients' preexisting comorbidities and how well they tolerate chemotherapy regimens, substitution with docetaxel or cisplatin might be considered. The



Primary Surgery TAH/BSO w/ tumor debulking and FIGO staging completed
Stage IA or IB, grade 1
Maintenance with bevacizumab q 3 weeks or PARP inhibitor
Stage IA or IB, grade 2 or 3, Stage IC or any Stage II, III or IV
CR
CR
Observation – follow-up once every 3 months for 5 years
CR
Consolidation with single agent taxane or platinum
PR
Six cycles taxane/platinum regimen (IP of IV)
PD or relapse within 6 months and poor candidate for chemotherapy
PD
PD or relapse within 6 months and good candidate for chemotherapy
Relapse/ recurrent disease > 6 months
CR
Combination Regimen:
Gemcitabine + cisplatin
Bevacizumab + gemcitabine, weekly paclitaxel, liposomal doxorubicin or cyclophosphamide
PD
Single Agent:
Docetaxel
Gemcitabine
Investigational agent
Liposomal doxorubicin
Topotecan
Bevacizumab
PD
PD or relapse within 6 months
Six cycles taxane/platinum regimen or platinum containing combination regimen or single agent PARP inhibitor
Single agent:

route of administration should also be discussed. Although intravenous (IV) administration is often used, intraperitoneal (IP) administration has been shown to improve overall survival and should be considered an option for first-line treatment; however, patient selection for IP therapy is critical[28,29] (Table 94–1). Close monitoring of organ function, nausea/vomiting, myelosuppression, and neuropathies is necessary for all taxane/platinum regimens (Table 94–2).

▶ *Intraperitoneal Chemotherapy*

For more than four decades, numerous investigators have evaluated the IP route for administration of chemotherapy; however, it was not until the third report of an improvement in overall survival that brought its use to the forefront in the first-line setting.[30] However, the benefits of IP chemotherapy has again become controversial after a recent report that compared IP chemotherapy to addition of bevacizumab and showed equivalent outcomes.[31] Current, there is no consensus among experts on whether IP chemotherapy should remain standard of care for first-line treatment of advanced ovarian cancer.

The principal theory supporting IP administration is to increase drug concentration in the site of disease, specifically the abdominal cavity. Patient characteristics greatly influence response and tolerability of IP chemotherapy. To be selected to receive IP chemotherapy for first-line treatment of ovarian cancer, the patient should have tumor optimally debulked and no bowel resection with primary surgery, normal renal and liver function, younger age, and no significant comorbidities.

Table 94–1

Summary of First-Line Chemotherapy Regimens for Advanced Ovarian Cancer

Gold standard first-line chemotherapy after initial surgery for treatment of ovarian cancer:

Paclitaxel 175 mg/m^2 IV infused over 3 hours + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles (+/− bevacizumab 7.5 mg/kg once every 3 weeks × 6 cycles followed by additional 12 cycles after completion of primary chemotherapy)

Alternative first-line regimen: Paclitaxel IV with substitution of carboplatin IV with cisplatin IP and addition of paclitaxel IP therapy:

Patient selection is critical: must have optimally debulked disease (< 1 cm) and no significant comorbidities; younger patients tolerate better

Day 1: paclitaxel 135 mg/m^2 IV infused over 24 hours + day 2: cisplatin 100 mg/m^2 IP infused over 1 hour + day 8: paclitaxel 60 mg/m^2 IP infused over 1 hour. Regimen is given once every 21 days × 6 cycles

Alternative first-line regimen: Dose density. Consider for patients with optimal debulking, no comorbidities, good performance status:

Paclitaxel 80 mg/m^2 IV infused over 1–3 hours once a week with carboplatin AUC = 6 IV infused over 1 hour on day 1 only of 21-day cycle

Alternative first-line regimen: Substitution of cisplatin in place of carboplatin. Consider for patients experiencing difficulty with maintaining platelet counts:

Paclitaxel 135 mg/m^2 IV infused over 24 hours + day 2: cisplatin 75 mg/m^2 IV infused over 4 hours. Regimen is given once every 21 days × 6 cycles

Alternative first-line regimen: Substitution of docetaxel in place of paclitaxel. Consider for patients with preexisting or increased risk of neuropathies:

Docetaxel 75 mg/m^2 IV infused over 1 hour + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles

AUC, area under the curve; IV, intravenous.

When IP therapy is administered, the placement of an IP catheter should occur at the time of surgery unless otherwise contraindicated. During IP administration, chemotherapy is delivered to the peritoneal space in 1 L of normal saline (NS) that has been warmed followed by another liter of NS to enhance drug distribution as tolerated.[30,31] The current standard IP regimen includes the administration of paclitaxel IV on day 1 followed by cisplatin IP on day 2 and then paclitaxel IP on day 8 given on a 21-day cycle for a total of six cycles (see Table 94–2). IP chemotherapy is difficult to tolerate with significant patient toxicity. The most common toxicities associated with IP administration include abdominal pain, myelosuppression, neurotoxicity, and catheter-related infections. The substitution of carboplatin IP in place of cisplatin remains investigational and should not be recommended outside a clinical trial protocol.

▶ *Neoadjuvant Chemotherapy*

Neoadjuvant chemotherapy is first-line treatment for patients who are poor surgical candidates or patients with bulky or significant tumor burden.[32] For patients who are poor surgical candidates because of significant comorbidities, a combination of taxane with platinum agent is administered every 21 to 28 days as tolerated with the intent to relieve symptoms and slow progression of disease. In some cases, especially in elderly patients, single-agent carboplatin is used as palliative treatment instead. Chemotherapy alone has not been curative for patients with advanced ovarian cancer.[33]

In patients with bulky disease or significant tumor burden, neoadjuvant chemotherapy can be used to decrease tumor burden to increase the likelihood of optimal tumor debulking during surgery.[33] Typically, three cycles of the standard combination taxane/platinum regimen is administered once every 21 days. After surgery, patient will receive another three to six cycles depending on their response to chemotherapy.

▶ *Consolidation and Maintenance Chemotherapy*

Consolidation chemotherapy is the addition of cycles of the taxane/platinum regimen or the addition of single-agent platinum or single taxane after completion of first-line chemotherapy.[34] If the tumor has a partial response (PR) to first-line chemotherapy evident by a significant decline in CA-125 by greater than 50% presurgery level and/or tumor regression or decrease in size, then cancer is still considered taxane/platinum sensitive. Additional cycles of chemotherapy are given until CR is achieved (see Figure 94–2). In 2014, bevacizumab was approved as the first targeted therapy for maintenance treatment for ovarian cancer based on the improved overall survival observed in the ICON-7 study.[35] First-line maintenance chemotherapy is similar to consolidation chemotherapy except maintenance chemotherapy is given to patients who have achieved a clinically CR.[35] The rationale for first-line maintenance chemotherapy is used to extend progression-free and overall survival by eliminating any microscopic disease present after completion of primary chemotherapy. Two agents from the class of poly(ADP-ribose) polymerase (PARP) inhibitors, niraparib and olaparib, have also demonstrated benefit in improving progression-free survival as maintenance therapy following achieving clinical CR to primary treatment.[36-41] PARP inhibitors were the second class of targeted therapy agents approved for first-line maintenance treatment of ovarian cancer. While greater benefit has been observed in the presence of *BRCA1* mutations, clinical benefit has been observed even in the absence of *BRCA1* mutations as well.[38,39] In 2020, the combination of bevacizumab plus PARP inhibitor has emerged as another approved option for first-line maintenance for ovarian cancer after CR achieved. In these studies, patients had received bevacizumab as part of primary chemotherapy treatment, and the addition of a PARP inhibitor to bevacizumab for first-line maintenance was associated with significant improvement in progression-free survival.[40,41] The potential financial toxicity should be taken into consideration when selecting optimal regimen for first-line maintenance for advanced ovarian cancer.

For an extensive description of the common agents used in first-line, consolidation, and maintenance chemotherapy of ovarian cancer, please see Chapter 88. A brief overview of the regimens is provided in Table 94–1, and adverse effects are provided in Table 94–2.

Chemotherapy After Recurrence

In the recurrent setting, platinum sensitivity of the tumor is assessed first. If recurrence occurs in less than 6 months or disease progresses while the patient is receiving a platinum-based regimen, the cancer is considered platinum resistant (see Figure 94–2). These parameters are also used to determine if tumors are taxane sensitive or resistant. However, patients

Table 94–2

Summary of Chemotherapy Agents Used for First-Line and Maintenance Treatment of Advanced Ovarian Cancer

Mechanism of Action of First-Line Agents
Platinum analogues: Produce intra- and interstrand cross-links and DNA adducts to disrupt DNA replication
Taxanes agents: Stabilize microtubules and prevent depolymerization of tubulin
Mechanism of Action of Maintenance Agents
PARP Inhibitors: Result in double-stranded DNA breaks that cannot be repaired in cancer cells with BRCA mutations
Antiangiogenic Agents: Inhibit VEGF-R, decrease microvasculator growth

Agent	Common Adverse Effects	Monitoring/Comments
First-Line		
Paclitaxel	Peripheral neuropathy (DLT), nausea/vomiting, alopecia, hypersensitivity reactions	Use caution with any elevation in AST (SGOT) Give proper dosing for liver dysfunction. At least a 50% dose reduction generally recommended Do not give if total bilirubin is > 5 mg/dL (86 μmol/L) Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine
Docetaxel	Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression	Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases > 1.5 times, the ULN should not receive docetaxel Do not give if biliary tract is obstructed Premedicate for hypersensitivity reactions: dexamethasone
Carboplatin	Myelosuppression (DLT), nephrotoxicity, nausea/vomiting, electrolyte wasting, diarrhea, stomatitis, hypersensitivity reactions	Prehydration not required If using BSA dosing, give proper dosing for renal dysfunction CrCl ≥ 60 mL/min (1.00 mL/s): no dosage adjustment needed CrCl 41–59 mL/min (0.68–0.99 mL/s): give 250 mg/m^2 CrCl 16–40 mL/min (0.26–0.67 mL/s): give 200 mg/m^2 CrCl ≤ 15 mL/min (0.25 mL/s): do not give NOTE: Calvert formula (AUC dosing) is based on renal function, so no additional dose adjustment is needed Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine Appropriate antiemetic regimen for prevention of acute and delayed nausea
Cisplatin	Neurotoxicity (DLT), nausea/vomiting, ototoxicity, nephrotoxicity, myelosuppression, electrolyte wasting, diarrhea	Prehydration and posthydration with electrolyte replacement (ie, potassium chloride 10 mEq [10 mmol] and magnesium sulfate 16 mEq [8 mmol]) required Do not use if SCr > 1.5 mg/dL (133 μmol/L) or BUN > 25 mg/dL (8.9 mmol/L) Give proper dosing for renal dysfunction CrCl 46–60 mL/min (0.77–1.00 mL/s): decrease dose by 50%. CrCl 31–50 mL/min (0.51–0.83 mL/s): decrease dose by 75%. CrCl ≤ 30 mL/min (0.50 mL/s): do not use Appropriate antiemetic regimen for prevention of acute and delayed nausea
First-line Maintenance		
Niraparib	Fatigue, nausea, thrombocytopenia, neutropenia, elevated liver function tests	Monitor CBC closely for first 4–6 weeks of treatment then monthly thereafter; Consider antiemetic PRN
Olaparib	Edema, fatigue, hypomagensemia, nausea, thrombocytopenia, neutropenia	Monitor CBC monthly Recommend antiemetics PRN
Rucaparib	Nausea, fatigue, elevations in liver function tests, rash, thrombocytopenia	1. Monitor CBC monthly 2. Recommend antiemetics PRN
Bevacizumab	Hypertension, proteinuria, infusion-related reactions, fluid retention, increase risk of thrombosis, myelosuppression	Monitor urine-to-creatinine baseline and every two cycles; hold therapy if ratio > 2 or measure urine protein every cycle and addition testing if positive for proteinuria Use caution in patients with a history of thrombosis

AST, aspartate aminotransferase; AUC, area under the curve; BSA, body surface area; BUN, blood urea nitrogen; CrCl, creatinine clearance; DLT, dose-limiting toxicity; SrCr, serum creatinine; ULN, upper limit of normal.

resistant to paclitaxel may still respond to docetaxel.[42] If the treatment goal is palliative care, then often single therapy will be used, but curative care typically is an aggressive combination regimen (see Figure 94–2 and Table 94–3). Immunotherapy, specifically pembrolizumab, has demonstrated modest benefit for patient with recurrent ovarian cancer that tumors have PDL-1 expression greater than 10%.[43] Sometimes an investigational agent may achieve responses equivalent or surpassing standard therapy and should be considered for most patients.

▶ *Platinum Sensitive*

In patients who experienced a CR to first-line chemotherapy and have had greater than a 6-month platinum-free interval, retreatment with a platinum-containing regimen is appropriate. The combination of carboplatin with gemcitabine, liposomal doxorubicin, or paclitaxel for the treatment of platinum-sensitive recurrent ovarian cancer with a curative intent is recommended[31,44,45] (see Table 94–3). However, in patients who are unable to tolerate additional combination chemotherapy regimens, carboplatin alone or any one of the second-line agents would be appropriate.[45]

Table 94–3

Summary of Regimens Used for Treatment of Recurrent Ovarian Cancer

Drug(s)	Regimen Dosing	Drug Monitoring Comments[b]
Combination Regimens		
Platinum Sensitive		
Paclitaxel and carboplatin	175 mg/m^2 IV (3-hour infusion) AUC 5–7.5 IV every 21 days	• Monitor closely for hypersensitivity reactions
Paclitaxel and cisplatin	135 mg/m^2 IV (24-hour infusion) 75 mg/m^2 IV	• Monitor closely for hypersensitivity reactions
Docetaxel and carboplatin	75 mg/m^2 IV AUC 5 IV every 21 days	• Monitor closely for hypersensitivity reactions
Gemcitabine and carboplatin	800 mg/m^2 IV days 1 and 8 AUC 5 IV day 1 every 21 days	• Monitor platelet counts closely • Monitor closely for hypersensitivity reactions
Liposomal doxorubicin and carboplatin	30 mg/m^2 IV over 1–3 hour AUC 5 IV every 28 days	• Monitor closely for hypersensitivity reactions • Liposomal doxorubicin infusion starts over 3 hour and decreases to 1 hour as tolerated • Counsel patient for PPE prevention
Niraparib	300-mg cap PO once daily	• Monitor CBC closely for first 4–6 weeks of treatment then monthly thereafter; dose reduction recommended in patients with platelet counts less than 150K • Consider antiemetics PRN
Olaparib	300-mg tab PO BID	• Monitor CBC monthly • Recommend antiemetics PRN
Rucaparib	600-mg tab BID	• Monitor CBC monthly • Recommend antiemetics PRN
Platinum-Resistant[a]		
Gemcitabine and cisplatin	1000 mg/m^2 IV days 1 and 15 40 mg/m^2 IV days 1 and 15 every 28 days	• Monitor renal function closely • Monitor ANC closely, consider primary use of growth factor • Monitor closely for hypersensitivity reactions
Liposomal doxorubicin and bevacizumab	40 mg/m^2 IV day 1 only and 10 mg/kg day 1 and day 15 every 28 days	• Liposomal doxorubicin infusion starts over 3 hour and decreases to 1 hour as tolerated • Counsel patient for PPE prevention • Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis
Gemcitabine and bevacizumab	800 mg/m^2 IV day 1 and day 15 and 10 mg/kg IV day 1 and day 15 every 28 days	• Use with caution in renal or liver dysfunction. No specific guidelines available • Counsel patient for PPE prevention • Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis
Paclitaxel and bevacizumab	80 mg/m^2 IV weekly days 1, 8, 15, and 21 and 10 mg/kg IV day 1 and 15 every 28 days	• Monitor closely for hypersensitivity reactions • Counsel patient for PPE prevention • Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis
Cyclophosphamide and bevacizumab	50 mg PO once daily 10 mg/kg IV once every 2 weeks every 28 days (continuous)	• Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis

[a] *Platinum resistance* = disease progression while on platinum agent or recurrence within 6 months of completion of platinum-based therapy.

[b] See Table 94–2 for specific monitoring parameters.

ANC, absolute neutrophil count; AUC, area under the curve; IV, intravenous; PO, oral; PPE, palmar-plantar erythrodysesthesia.

The PARP inhibitors (niraparib, olaparib, and rucaparib) are also approved for the treatment of platinum-sensitive recurrent ovarian cancer.[36,41] The terminology "switch maintenance" has emerged in management of recurrent, platinum-sensitive ovarian cancer. If patients have stable disease on a platinum-containing regimen and perhaps experiencing toxicity or just desire break from infusions, switching maintenance regimen over to oral PARP inhibitor has become common clinical practice to provide break from IV chemotherapy (see Table 94–2).

▶ *Platinum Resistant*

Recurrent or persistent ovarian cancer after platinum-based regimens has a discouraging prognosis. **KEY CONCEPT** Single-agent chemotherapy is standard practice for recurrent platinum-resistant ovarian cancer. Weekly paclitaxel achieves a response rate of 13%–50%, while liposomal doxorubicin achieves a response rate of 20% in this population and are the most commonly used regimens. In addition, two combination regimens have demonstrated promising activity in the recurrent setting: (a) gemcitabine plus cisplatin because gemcitabine may modulate platinum resistance, allowing it to regain its cytotoxic activity, and (b) bevacizumab with metronomic oral cyclophosphamide.[46-48] Other active agents include endocrine therapy, gemcitabine, liposomal doxorubicin, topotecan, bevacizumab, pembrolizumab, or investigational agents. In 2016, the FDA approved the addition of bevacizumab with paclitaxel, gemcitabine, or liposomal doxorubicin to improve outcomes in the recurrent ovarian cancer setting[49] (see Figure 94–2). **KEY CONCEPT** Because the efficacy of the agents is similar, the selection of agent for treatment of recurrent platinum-resistant ovarian cancer is dependent on residual toxicities, clinician preference, and patient convenience. Table 94–4 gives a short summary of the adverse effects and monitoring parameters for chemotherapy agents commonly used for the treatment of recurrent ovarian cancer.

OUTCOME EVALUATION

Overall survival is impacted by success of initial surgery to debulk tumor to less than 1 cm of disease and response to first-line chemotherapy. The CA-125 level should be monitored with each cycle, and at least a 50% reduction in CA-125 after four cycles of taxane/platinum chemotherapy is related to an improved prognosis. Patients who achieve CR should have follow-up examinations once every 3 months, including CA-125, physical examination, and pelvic examination, and appropriate diagnostic scans (ie, computed tomography [CT], magnetic resonance imaging [MRI], or positron emission tomography [PET] scan) should be evaluated for the detection of disease. While evaluating the patient, specifically assess resolution of any residual chemotherapy-related adverse effects including neuropathies, nephrotoxicity, ototoxicity, myelosuppression, or nausea/vomiting. Younger patients with an active menstrual cycle before surgery will encounter "surgical menopause" and often experience intense hot flushes. Because there are concerns about potential of hormones in the pathogenesis of ovarian cancer, the use of hormone replacement therapy is controversial. However, based on recent large retrospective analysis, it appears that hormone replacement with estrogen is safe and does not increase future risk of breast cancer or risk of recurrence of ovarian cancer.[50] The use of phytoestrogen supplements, such as black cohosh or soy, is also controversial. Alternative nutritional supplements with less controversy may include omega-3 (fish oil), fiber supplement, or maca root. An effective alternative has been the use of the class of serotonin reuptake inhibitors such as venlafaxine or sertraline.

Patient Encounter 3

A 67-year-old woman with history of stage IIIa high-grade, clear-cell carcinoma of the ovary had optimal tumor debulking and achieved clinical complete response to adjuvant chemotherapy with paclitaxel/carboplatin returns for her 6-month surveillance visit. Previous genetic testing revealed she and her tumor were negative for presence of any mutations and she is PDL-1 negative. CT scan reveals peritoneal implants and two enlarged lymph nodes and slight fluid accumulation in abdominal cavity. Her CA-125 is 67 U/mL (67 kU/L) today. She has history of poorly controlled diabetes and suffered significant peripheral neuropathy during her primary treatment leading to dose reduction of her paclitaxel to 135 mg/m^2 and initiation of gabapentin 300 mg three times a day. She continues to take the gabapentin but reports improvement of her peripheral neuropathy today.

Explain how to decide patient's tumor is platinum sensitive or resistant.

What tumor characteristics can you identify that would have suggested this patient was at higher risk for early recurrence?

Today is patient's first recurrence, compare and contrast treatment options to offer to this patient.

In the PD or recurrent setting, CA-125 levels should still be monitored with each cycle, but no change in therapy is recommended until after minimum of three cycles of chemotherapy. In addition, appropriate diagnostic scans (ie, CT scan, MRI, or PET scan) should be evaluated once every three cycles. Patients should also have routine physical examinations with each cycle of chemotherapy to evaluate for any physical toxicity associated with chemotherapy such as neuropathies, fluid retention, palmar-plantar erythrodysesthesia, myelosuppression, or nausea/vomiting.

Unfortunately, most patients will eventually progress through all chemotherapy options, and supportive care measures should be provided to maintain patient comfort and quality of life. Common complications while developing a plan for treatment of advanced or progressive ovarian cancer include ascites, uncontrollable pain, and SBO. Precaution should be used in removal of ascites because of the potential complications associated with rapid fluid shifts. Liberal use of opioids to control pain is appropriate as ovarian cancer patients cope with PD and approaching end of life. Appropriate bowel regimens with laxatives and stool softeners should be used to prevent constipation. However, when a patient with a well-controlled bowel regimen presents with new onset of constipation, additional workup is required before altering the bowel regimen. **KEY CONCEPT** In ovarian cancer patients, SBO is a common complication of progressive disease. In general, laxatives should not be used in patients with SBOs. Before treating constipation, patients should have a physical examination and abdominal X-ray to rule out SBO. Often, palliative surgery is required to correct SBO and alleviate patient pain. Patients should not eat any solid or liquids until resolution of SBO. If inoperable SBO exists, then parenteral nutrition can be considered but weighed against ultimate treatment objectives. Overall, providing any measures needed to maintain patient comfort is the priority for patients with progressive ovarian cancer.

Table 94–4

Summary of Chemotherapy Single-Agent Regimens Used for Treatment of Progressive and Recurrent Platinum-Resistant Ovarian Cancer

Agent	Dose	Response Rate (%)	Common Adverse Effects	Monitoring/Comments
Docetaxel	75 mg/m^2 IV over 1 hour repeat every 21–28 days vs 30–40 mg/m^2 IV over 1 hour once every week	22 NR	Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression	1. Premedicate for hypersensitivity reactions with dexamethasone 2. Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases > 1.5 times the ULN should not receive docetaxel 3. Do not give if the biliary tract is obstructed
Gemcitabine	800 mg/m^2 IV infused over 30 minutes once a week on days 1, 8, and 15 followed by 1 week of rest	13.9–27	Myelosuppression (DLT), flulike symptoms, headache, somnolence, nausea/vomiting, stomatitis, diarrhea, constipation, rash	1. Use with caution in renal or liver dysfunction. No specific guidelines available
Liposomal doxorubicin	40 mg/m^2 IV infused over 3 hours cycle 1 and 2; then infused over 1 hour; thereafter repeat every 28 days	12.3–18	Myelosuppression, stomatitis, mucositis, alopecia, flushing, shortness of breath, hypotension, headaches, cardiotoxicity, hand–foot syndrome	1. Give proper dosing for liver dysfunction; total bilirubin 1.2–3 mg/dL (21–51 μmol/L): reduce dose by 50%; total bilirubin ≥ 3 mg/dL (51 μmol/L): reduce dose by 75% 2. Do not give if total bilirubin is > 5 mg/dL (86 μmol/L)
Topotecan	1.5 mg/m^2 IV infused over 30 minutes on days 1, 2, 3, 4, and 5; repeat every 21 days *OR* 4 mg/m^2 IV infused over 30 minutes once a week for 3 consecutive weeks followed by 1-week rest	6.5–17 31	Myelosuppression (DLT), nausea/vomiting, diarrhea, stomatitis, abdominal pain, alopecia, AST/ALT elevation	1. Give proper dosing for renal dysfunction; CrCl 40–60 mL/min (0.67–1.00 mL/s): no dosage adjustment needed; CrCl 20–39 mL/min (0.33–0.66 mL/s): reduce dose by 50% 2. Do not give if CrCl < 20 mL/min (0.33 mL/s)
Altretamine (Hexalen)	260 mg/m^2 PO daily for 14–21 days; repeat every 28 days	9.7	Nausea/vomiting, diarrhea, abdominal cramping, myelosuppression	1. Monitor for potential CYP450 drug interactions
Capecitabine	1800–2500 mg/m^2 PO as divided dose twice daily for 14 consecutive days followed by 1 week of rest	29	Myelosuppression, hand–foot syndrome, nausea/vomiting, edema, stomatitis, diarrhea, cardiotoxicity, rash	1. Monitor for PPE and recommend regular use of lotions on hands and feet 2. Use with caution in renal dysfunction; CrCl ≥ 51 mL/min (0.84 mL/s): no dose adjustment; CrCl 30–50 mL/min (0.50–0.83 mL/s): reduce dose by 25%; CrCl < 30 mL/min (0.50 mL/s): do not give 3. Use with caution in liver dysfunction; no specific guidelines available
Etoposide	50 mg/m^2/day PO in divided doses given daily for 3 weeks followed by 1 week of rest	18	Myelosuppression, nausea/vomiting, anorexia, alopecia, headache, fever, hypotension	1. Give proper dosing for liver dysfunction; total bilirubin 1.5–3 mg/dL (26–51 μmol/L): decrease dose by 50%; total bilirubin 3–5 mg/dL (51–86 μmol/L): decrease dose by 75% 2. Do not give if total bilirubin is > 5 mg/dL (86 μmol/L) 3. Give proper dosing for renal dysfunction; CrCl 60–45 mL/min (1.00–0.75 mL/s): reduce dose by 15%; CrCl 44–30 mL/min (0.74–0.50 mL/s): reduce dose by 20%; CrCl < 30 mL/min (0.50 mL/s): reduce dose by 25%
Letrozole	2.5 mg once daily	15	Headache, nausea, dyspepsia, skin rash	1. No protective effect on bone; recommend calcium supplementation
Tamoxifen	20 mg PO twice a day continuously until PD	10	Thrombocytopenia, anemia, thromboembolism, hot flashes, decreased libido, nausea/vomiting	1. Protective effect on bone and lipids 2. Increased risk for endometrial cancer

(Continued)

Table 94–4

Summary of Chemotherapy Single-Agent Regimens Used for Treatment of Progressive and Recurrent Platinum-Resistant Ovarian Cancer (*Continued*)

Agent	Dose	Response Rate (%)	Common Adverse Effects	Monitoring/Comments
Vinorelbine	30 mg/m^2 IV infused over 15 minutes on days 1 and 8; repeat every 21 days	29	Constipation, neutropenia, anemia, thrombocytopenia, neurotoxicity	1. Consider bowel regimen to prevent constipation
Bevacizumab	15 mg/kg IV infused over 30–90 minutes every 21 days	NR	Hypertension, proteinuria, infusion-related reactions, fluid retention, increase risk of thrombosis, myelosuppression	1. Monitor urine-to-creatinine baseline and every two cycles; hold therapy if ratio > 2 or measure urine protein every cycle and addition testing if positive for proteinuria 2. Use caution in patients with a history of thrombosis
Pembrolizumab	200 mg IV once every 21 days	10	Immune-related toxicities, rash, hypothyroidism, diarrhea, pneumonitis, fatigue	1. Close monitoring for dermatologic rash, change in thyroid function, gastrointestinal symptoms. 2. Use caution in patients with history of significant bowel obstructions.

CrCl, creatinine clearance; DLT, dose-limiting toxicity; IV, intravenous; NR, not reported; PD, progressive disease; PO, oral; PPE, palmar-plantar erythrodysesthesia; ULN, upper limit of normal.

Patient Care Process

Collect Information:

- Perform medication history for use of prescription and nonprescription medications and nutritional/herbal supplements. Confirm drug allergies/intolerances.
- Review the medical history, family cancer history, and current physical and laboratory assessment findings.
- Speak with patient and review records to identify socioeconomic factors that may affect medication access or compliance with care plan.

Assess the Information:

- Evaluate current symptoms and signs that are disease-related and would be associated with new diagnosis or drug-related side effects from prior treatment.
- Evaluate medication list to determine if there are any potential interactions, therapy duplication, or unnecessary medications. Determine if there is any need for acute or chronic pain medications.
- Review laboratory tests, diagnostic testing, and BRCA1/2 testing.
- Based on family cancer history, determine if additional genetic testing is recommended.
- Review chemotherapy history to determine potential for platinum sensitivity/resistance and consider genetic mutation status in selection of treatment options.

Develop a Care Plan:

If patient is a surgery candidate:

- Evaluate patient comorbidities to determine if additional workup is necessary before tumor debulking surgery.
- Decide if any medications or supplements need to be stopped or changed before surgery (ie, aspirin, warfarin, nonsteroidal anti-inflammatory agents, and omega-3s).

If patient is a chemotherapy candidate:

- Evaluate patient medications, residual toxicities, renal function, and liver function to determine if any potential dose adjustments ought to be recommended for the selected chemotherapy regimen (see Figure 94–2).
- Determine whether patient has insurance coverage for planned chemotherapy regimen and supportive care medications as indicated. Discuss if potential copays are financially feasible as well.

Implement the Care Plan:

Surgery:

- Review plan to use low molecular weight heparin for postoperation thrombosis prevention and submit request for insurance approval. Teach nonpharmacologic recommendations for thrombosis prevention post surgery.
- Discuss when any medications/supplements should be stopped and when to resume in relation to timing of surgery.
- Review the plan for acute pain management postoperation as well as bowel regimen to prevent constipation/reduce straining after abdominal surgery.

Chemotherapy:

- Provide appropriate patient education on chemotherapy agents. Explain treatment intent—curative verses palliative (relief of symptoms) and the plan for monitoring response to treatment.
- Explain prevention and management of expected side effects such as infection, nausea and vomiting, neuropathy, electrolyte wasting, and bowel habits.

(*Continued*)

Patient Care Process (*Continued*)

Follow-up: Monitor and Evaluate:

- After surgery, patient should have follow-up 2 to 3 weeks to evaluate wound healing, pain control/resolution, and determine if adjuvant chemotherapy is required.
- While on chemotherapy, patient should have a follow-up every cycle to assess symptom control and chemotherapy tolerability.
- A CBC with differential should be checked prior to each chemotherapy dose with complete laboratory values evaluated each cycle.
- Chemotherapy doses should be decreased or discontinued for unacceptable toxicity or organ dysfunction when indicated.
- Tumor markers are also monitored with each cycle but not acted upon unless greater than 50% increase or consistent trend upward each cycle.
- Assess tumor response to chemotherapy once every 3 months with CT scan/MRI/PET scan as indicated. Follow current RECIST criteria to determine stable disease, response, or progression of disease.

Abbreviations Introduced in This Chapter

AUC	Area under the curve
BRCA1	Breast cancer activator gene 1
BRCA2	Breast cancer activator gene 2
BSO	Bilateral salpingo-oophorectomy
CA-125	Cancer antigen-125
CA-19	Cancer antigen-19
CEA	Carcinoembryonic antigen
CR	Complete response
CrCl	Creatinine clearance
DLT	Dose-limiting toxicity
FIGO	International Federation of Gynecology and Obstetrics
HBOC	Hereditary breast and ovarian cancer
HNPCC	Hereditary nonpolyposis colorectal cancer
IP	Intraperitoneal
LFT	Liver function test
LOH	Loss of heterozygosity
NS	Normal saline
OC	Oral contraceptive
PARP	Poly(ADP-ribose) polymerase
PD	Progressive disease
PET	Positron emission tomography
PR	Partial response
SBO	Small bowel obstruction
TAH	Total abdominal hysterectomy
TVUS	Transvaginal ultrasound

Lymphomas

Keith A. Hecht and Susanne Liewer

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Discuss the underlying pathophysiologic mechanisms of the lymphomas and how they relate to presenting symptoms of the disease.
2. Differentiate the pathologic findings of Hodgkin lymphoma (HL), follicular indolent non-Hodgkin lymphoma (NHL), and diffuse aggressive NHL and how this information yields a specific diagnosis.
3. Describe the general staging criteria for the lymphomas and how it relates to prognosis; evaluate the role of the prognostic systems such as the International Prognostic Score for HL, the Follicular Lymphoma International Prognostic Index (IPI), and the IPI for diffuse, aggressive NHL.
4. Compare and contrast the treatment algorithms for early and advanced stage disease for HL.
5. Assess the role of autologous hematopoietic stem-cell transplantation for relapsed lymphomas.
6. Delineate the clinical course of follicular indolent and diffuse aggressive NHL and the implications for disease classification schemes and treatment goals.
7. Outline the general treatment approach to follicular indolent and diffuse aggressive NHL for localized and advanced disease.
8. Interpret the current role for monoclonal antibody therapy in NHL.

INTRODUCTION

The malignant lymphomas are a clonal disorder of hematopoiesis with the primary malignant cells consisting of lymphocytes of B-, T-, or natural killer (NK) cell origin. Lymphoma cells predominate in the lymph nodes; however, they can infiltrate lymphoid and nonlymphoid tissues, such as the bone marrow, central nervous system (CNS), gastrointestinal (GI) tract, liver, mediastinum, skin, and spleen. An overview of the lymph node regions typically involved in lymphomas is depicted in Figure 95–1. **KEY CONCEPT** There are two broad classifications of lymphoma, Hodgkin lymphoma (HL) and non-Hodgkin lymphoma (NHL), and both contain numerous histologic subtypes that are pathologically distinct disease entities.

The clinical course varies widely among histologies of lymphoma. More aggressive subtypes are highly proliferating cells that require aggressive therapeutic intervention with chemotherapy, radiation therapy, or both. By contrast, certain subtypes of NHL are characterized by a disease course that flares and remits intermittently over a period of years regardless of treatment.

HODGKIN LYMPHOMA

EPIDEMIOLOGY AND ETIOLOGY

Approximately 8830 new cases of HL were estimated to be diagnosed in the United States in 2021, with 960 deaths attributed to the disease.[1] Broadly, HL is divided into two types, classical HL and nodular lymphocyte-predominate HL. Classical Hodgkin lymphoma makes up approximately 95% of HL cases and will be the focus of this chapter. The incidence of HL is bimodal, with peaks occurring in the third decade of life and in patients over 50.[2] The precise cause of HL is unknown, but certain associations have been reported and provide insight about possible etiologic factors. Epstein-Barr virus (EBV) has been associated with HL, its viral genome is detected in Reed–Sternberg (RS) cells in up to 40% of cases in developed countries. Other viruses (cytomegalovirus, human herpes viruses, human immunodeficiency virus [HIV], and adenoviruses) have been associated with HL; however, data is conflicting.[3] Other possible risk factors identified include woodworking and a familial history of HL.

PATHOPHYSIOLOGY

Pluripotent stem cells in the bone marrow are able to differentiate to both lymphoid and myeloid progenitor cells. Lymphoid progenitor cells undergo normal gene rearrangement to yield either B-cell or T-cell lineage precursor cells. Normal maturation for naive B cells includes expression of cell surface antibody or the cells undergo apoptosis. These cells are differentiated from other B cells, such as memory cells, by virtue of cell surface antigen ($CD5^+$ or $CD5^-$ and $CD27^-$) and bound antibody (IgM+ and IgD+). When naive B cells recognize antigen with their cell surface antibody, they accumulate in the lymph nodes, spleen, or other lymphoid tissue.

The pathophysiology of HL is defined by the presence of the RS cell in a grouping of lymph nodes. The RS cell is a morphologically large cell with a multinucleated structure possessing pronounced eosinophilic nucleoli, thought to be B cell in origin.[4] In the affected lymph nodes, the RS cells are contained within an inflammatory background that is believed to be essential for their survival. RS cells have lost the expression of most B-cell markers.

FIGURE 95–1. Lymph node regions used in describing the extent of lymphoma involvement. (Reproduced with permission from DiPiro JT, Yee GC, Posey LM, et al. (eds). Pharmacotherapy: A Pathophysiologic Approach, 11th ed. New York: McGraw-Hill; 2020: Fig. 149–1.)

Common cell-surface antigens expressed by RS cells include CD30 and CD15, but other common B-cell antigens, such as CD20, are inconsistently expressed.[4] The Janus kinase-signal transduction and transcription (JAK-STAT) signaling pathway has also been found to be active in HL. Additionally, the overexpression of nuclear factor kappa-B (NF-κB), a proliferative and antiapoptotic transcription factor nuclear factor, is believed to contribute to the expansion and survival of RS cells.

HL is classified into disease subtypes based on the number and morphologic appearance of RS cells and the background cellular background. These are listed in the World Health Organization (WHO) classification of lymphoid neoplastic diseases in Table 95–1.[5] Nodular sclerosing (75%) is the most common form of classical HL. It is more common in young adults and marked by the presence of the RS variant cell, the lacunar cell. The second most common form of HL is mixed-cellularity variant (19%), with others accounting for the remainder of cases.[6] Factors identified as negative disease prognostic indicators are listed in Table 95–2.

TREATMENT OF HL

Desired Outcome

Staging of HL with a standard classification is necessary to guide treatment. The extent and location of involvement, localized or disseminated extranodal disease, and B symptoms are factors in assignment of stage. The Lugano modification of the original Ann Arbor classification is used in staging lymphomas and outlined in Table 95–3.[7] The role of PET imaging (including integrated PET and CT) is critical for accurate initial staging and assessing outcome of therapy. The Deauville criteria use a five-point scale that describes the ^{18}F-fluorodeoxyglucose uptake in the involved lymphoma sites. Interim or end of treatment PET scans with a Deauville score of 1, 2, or 3 are considered negative and scores of 4 and 5 are considered positive for disease.[8] PET positivity at the end of treatment is associated with poor outcomes. PET scans completed during therapy (interim PET imaging) can assess response to treatment and can help guide clinicians to escalate or deescalate therapy.

KEY CONCEPT The principal goal in treating HL is to cure the patient of the primary malignancy. HL is sensitive to both radiation and chemotherapy, resulting in an 80% rate of cure with modern therapy. Treatment strategy is generally divided into approaches for early stage I/II disease and stage III/IV advanced disease. Patients with stage I/II disease are further classified into favorable, unfavorable with bulky disease, and unfavorable with nonbulky disease. Regardless of stage, all patients are treated with curative intent. Other treatment goals include:

- Complete resolution of disease symptoms
- Incorporation of supportive care measures to optimize quality of life
- Minimization of acute and long-term treatment-related toxicity

Table 95–1

Abbreviated WHO Classification of Lymphoid Neoplasms

B-Cell Neoplasms
Chronic lymphocytic leukemia/small lymphocytic lymphoma
Monoclonal B-cell lymphocytosis
B-cell proliferative leukemia
Splenic marginal zone B-cell lymphoma
Hairy-cell leukemia
Lymphoplasmacytic lymphoma
Monoclonal gammopathy of undetermined significance
Plasma-cell myeloma
Plasmacytoma
Monoclonal immunoglobulin deposition disease
Extranodal marginal zone B-cell lymphoma of MALT type
Nodal marginal zone lymphoma
Follicular lymphoma
Primary cutaneous follicle center lymphoma
Mantle-cell lymphoma
Diffuse large B-cell lymphoma (DLBCL)
Primary DLBCL of central nervous system
Primary cutaneous DLBCL
Lymphomatoid granulmatosis
Primary mediastinal large B-cell lymphoma
Plasmablastic lymphoma
Primary effusion lymphoma
Burkitt lymphoma

T-Cell and NK-Cell Neoplasms
T-cell prolymphocytic leukemia
T-cell large granular lymphocytic leukemia
Aggressive NK-cell leukemia
Hydroa vacciniforme-like lymphoproliferative disorder
Adult T-cell lymphoma/leukemia (HTLV1+)
Extranodal NK/T-cell lymphoma, nasal type
Enteropathy-associated T-cell lymphoma
Monomorphic epitheliotropic intestinal T-cell lymphoma
Hepatosplenic T-cell lymphoma
Subcutaneous panniculitis-like T-cell lymphoma
Mycosis fungoides
Sézary syndrome
Primary cutaneous T-cell lymphoproliferative disorders
Peripheral T-cell lymphoma
Angioimmunoblastic T-cell lymphoma
Follicular T-cell lymphoma
Anaplastic large-cell lymphoma

Hodgkin Lymphoma
- Nodular lymphocyte-predominant HL
- Classical HL
  - Nodular sclerosis HL
  - Lymphocyte-rich classical HL
  - Mixed cellularity HL
  - Lymphocyte depletion HL

Posttransplant Lymphoproliferative Disorders

Histiocytic and Dendritic Cell Neoplasms

AML, acute myeloid leukemia; HL, Hodgkin lymphoma; MALT, mucosa-associated lymphoid tissue; NK, natural killer.

Table 95–2

Negative Prognostic Factors for HL

Stages I–II HL as defined by NCCN
Age 50 years or older
ESR > 50 or any B symptoms
MMR > 0.33
> 3 nodal site
Bulky disease > 10 cm

International Prognostic Score—Advanced HL
Albumin < 4 g/dL (40 g/L)
Hemoglobin < 10.5 g/dL (105 g/L; 6.52 mmol/L)
Male sex
Age older than 45 years
Stage IV disease
WBC over15,000/mm^3 (15 $\times$ 10^9/L)
Lymphocytopenia (count < 600/mm^3 [0.6 $\times$ 10^9/L], < 8% [0.08] of WBC count, or both)

WBC, white blood cell.

ESR, erythrocyte sedimentation rate; MMR, mediastinal mass ration (maximum width of mass/maximum intrathoracic diameter); NCCN, National Comprehensive Cancer Network.

Nonpharmacologic Therapy

Radiation therapy is effective in the treatment of HL and has cured patients of their disease. Historically, patients with favorable early stage I/II disease were treated with radiation alone. However, long-term toxicities associated with this practice have precluded this approach. Current treatment strategies combine radiation with chemotherapy to reduce the irradiated volume and dose as well as the number of cycles of chemotherapy.

Today, the use of involved-site radiotherapy (ISRT) and involved-node radiotherapy (INRT) limits radiation to the involved area sparing other organs.[9] Acute effects of irradiation are typically transient and include nausea, anorexia, xerostomia, dysgeusia, pharyngitis, dry cough, fatigue, diarrhea, and rash. Delayed effects from radiotherapy are concerning as they may be permanent and present months to years after therapy. Pneumonitis, pericarditis, hypothyroidism, infertility (with pelvic field irradiation), coronary artery disease, deformities in bone and muscle

Table 95–3

Lugano Staging Classification for Lymphomas (2014 Modification of Ann Arbor Staging)

Stage	Involvement	Extranodal (E) Status
Limited		
Stage I	One node or a group of adjacent nodes	Single extranodal lesions without nodal involvement
Stage II	Two or more nodal groups on the same side of the diaphragm	Stage I or II by nodal extent with limited contiguous extranodal involvement
Stage II bulky	Same as II but with "bulky" disease	
Advanced		
Stage III	Nodes on both sides of diaphragm or nodes above the diaphragm with spleen involvement	Not applicable
Stage IV	Additional noncontiguous extralymphatic involvement	Not applicable

"A" (absence of B-symptoms) or "B" (presence of B-symptoms) is only used for Hodgkin lymphoma.

Clinical Presentation and Diagnosis of Malignant Lymphomas

General

Nonspecific; can range from an asymptomatic patient with a less aggressive lymphoma to a patient who is gravely ill with advanced disease.

KEY CONCEPT Symptoms

- Lymphadenopathy, generally in the cervical, axillary, supraclavicular, or inguinal lymph nodes
- Splenomegaly
- Shortness of breath, dry cough, chest pressure (patients with mediastinal mass)
- GI complications (nausea, vomiting, early satiety, constipation, and diarrhea)
- Back, chest, or abdominal pain

Signs

- Fever[a]
- Night sweats[a]
- Weight loss greater than 10% within last 6 months[a]
- Pruritus

Laboratory Tests

- LDH
- ESR
- Serum chemistries
- CBC with differential

KEY CONCEPT Other Diagnostic Tests

- Physical examination with careful attention to lymph node inspection.
- Imaging—chest X-ray, chest CT, abdominal or pelvic CT; integrated PET and CT are recommended as part of the initial workup.
- Bone marrow biopsy.
- Biopsy of suspected lymph node(s)—either open lymph node biopsy (preferred) or core biopsy; fine needle aspiration should only be performed if preferred biopsy methods are unobtainable.
- Hematopathology evaluation of biopsy specimen—morphologic inspection, immunohistochemistry for cell surface antigens to characterize lymphoma cells, cytogenetic analysis.

---

[a] Known collectively as B symptoms.

CBC, complete blood count; CT, computed tomography; ESR, erythroid sedimentation rate; LDH, lactate dehydrogenase; PET, positron emission tomography.

growth in children, herpes zoster reactivation, and Lhermitte sign are not uncommon. Patients cured with radiotherapy are at increased risk for new cancers of the breast, lung, and stomach, as well as melanoma and new NHL, depending on the radiation field.

Patient Encounter Part 1: Initial Presentation

A 63-year-old man with a medical history of hypertension and COPD presents to the oncologist on referral from his primary care provider. He presented to his PCP with swollen lymph nodes and facial swelling. He was in his usual state of health until 2 months ago when he began experiencing "lumpy spots" in his bilateral axillary region and swelling in the neck. He states that he has experienced a 20-lb weight loss over the last several months. The PCP referred him for biopsy of palpable cervical lymph node. A fine needle aspiration was performed that showed a "lymphoproliferative process." Complete blood count revealed a WBC of 18,500/mm^3 (3.5 × 10^9/L), hemoglobin of 8.5 g/dL (8.5 g/L; 5.27 mmol/L), and platelets were 137,000/mm^3 (137 × 10^9/L). LDH was 353 U/L (5.9 μkat/L). The chemistry panel was unremarkable.

What tests should be performed to confirm a diagnosis of lymphoma and determine its overall stage?

Based on the information provided, what is his international prognostic score (IPS), and how does it impact treatment selection?

Pharmacologic Therapy

▶ *Early-Stage Disease*

KEY CONCEPT Initial treatment of HL includes combination chemotherapy; these regimens are effective and have acceptable long-term toxicities. Combined modality therapy for favorable disease consists of two cycles ABVD (doxorubicin, bleomycin, vinblastine, and dacarbazine) followed by an interim PET (characteristics described in Table 95–2). For Deauville scores of 1 to 3, patients receive 20 Gy (Gray, the absorbed radiation dose) of ISRT.[10] Deauville score of 4 would receive 2 additional cycles of ABVD (total of 4) followed by 30-Gy ISRT. Patients with a positive Deaville score of 5 should have a biopsy to determine if persistent disease is present. Patients with a positive biopsy should be treated for refractory disease. Chemotherapy alone for favorable disease can be considered. After two cycles of ABVD, patients with a Deauville score of 1 to 3 may receive one to two additional cycles of ABVD.[11] Patients with Deauville scores of 4 receive two additional cycles of ABVD or two cycles of BEACOPP.[12]

ABVD followed by interim PET scans guide therapy for patients with stages I and II unfavorable bulky or nonbulky disease. Negative Deauville scores receive two additional cycles of ABVD (or AVD for bulky disease) and ISRT. However, Deauville scores of 4 are recommended to receive two cycles of BEACOPP (2–3 cycles for bulky disease) and ISRT.[11] Another option for patients with unfavorable nonbulky disease would be two cycles of BEACOPP and two cycles of ABVD followed by ISRT for patients with a Deauville score of 1 to 4.[13] All patients with Deauville score of 5 should undergo a biopsy to determine if lymphoma is present. Individuals with positive biopsies are treated for refractory HL. A list of chemotherapy regimens used in HL is presented in Table 95–4.

Table 95–4

Common Treatment Regimens in HL

ABVD—Every 28 Days
Doxorubicin 25 mg/m^2 IV × 1, days 1 and 15
Bleomycin 10 units IV × 1, days 1 and 15
Vinblastine 6 mg/m^2 × 1, days 1 and 15
Dacarbazine 375 mg/m^2 IV × 1, days 1 and 15

AVD—Every 28 Days
Doxorubicin 25 mg/m^2 IV × 1, days 1 and 15
Vinblastine 6 mg/m^2 × 1, days 1 and 15
Dacarbazine 375 mg/m^2 IV × 1, days 1 and 15

BEACOPP (Escalated)—Every 21 Days
Bleomycin 10 mg/m^2 IV, day 8
Etoposide 200 mg/m^2 IV, daily × days 1–3
Doxorubicin 35 mg/m^2, day 1
Cyclophosphamide 1200 mg/m^2 IV, day 1
Vincristine 1.4 mg/m^2 IV, day 8
Procarbazine 100 mg/m^2 po daily, days 1–7
Prednisone 40 mg po daily, days 1–14

BEAM (High-Dose with Autologous SCT)[a]
Carmustine 300 mg/m^2 IV × 1 day
Etoposide 100–200 mg/m^2 IV every 12 hours × 4 days
Cytarabine 100–200 mg/m^2 IV every 12 hours × 4 day
Melphalan 140 mg/m^2 IV × 1 day

[a] Used for both Hodgkin lymphoma and non-Hodgkin lymphoma.

IV, intravenous; po, oral; SCT, stem-cell transplantation.

▶ *Advanced Disease*

Patients with advanced disease can be further classified into two groups based on IPS (Table 95–2). Patients with three or fewer poor prognostic factors are considered to have favorable disease while patients with four or more factors have unfavorable disease. Patients with unfavorable disease may warrant more aggressive treatment.

The chemotherapy regimen MOPP (mechlorethamine, vincristine, procarbazine, and prednisone) is of historical significance because it was the first chemotherapy regimen to cure HL in the 1960s. However, significant toxicity, including sterility and secondary leukemia, led to the development of new regimens. ABVD remains the preferred initial regimen for most patients with advanced HL. Two cycles ABVD are recommended followed by interim PET. The omission of bleomycin from the ABVD regimen has been evaluated. Exclusion of bleomycin (AVD regimen) decreases pulmonary toxicity without compromising outcomes (Table 95-5).[14] For a Deauville score of 1 to 3, four cycles of AVD are administered (total of 6). For patients with a Deauville score of 4, two cycles of ABVD or two cycles of escalated BEACOPP are recommended followed by a PET to assess response. Responses with a Deauville response of 1 to 3, two additional cycles of BEACOPP (total of 4) or ABVD (total of 6) are needed. Any patient with a Deauville score of 5 should undergo a biopsy. Patients with a positive biopsy should be treated as those patients with refractory disease.

Patients with advanced disease, IPS score > 4, and age less than 60 years may consider BEACOPP for two cycles as initial therapy.[15] For patients with an interim PET with a Deauville score of 1 to 3 may receive two additional cycles of BEACOPP (total of 4) or 4 cycles of ABVD (or AVD) followed by a PET to assess response. A Deauville score of 4 should receive two additional cycles of BEACOPP (total of 4) followed by a PET. Patients with a negative Deauville receive two additional cycles of BEACOPP (total of 6). Patients with a Deauville score of 4 or 5 should have a biopsy to determine response to therapy. While dose-escalated BEACOPP regimen is considered for patients with advanced HL with a high number of poor prognositic factors, it should be noted it is associated with more toxicity including infertility and secondary leukemia. Brentuximab with AVD may also be considered in this patient population. Patients should be free from symptoms of neuropathy, have an IPS score >4, and have a contraindication for bleomycin.[16]

Despite the high success rate in treating HL, approximately 5% to 10% of patients will be refractory to initial treatment and 10% to 30% will relapse after initial response.[17] Patients relapsing after treatment should be offered additional therapy as durable responses have been reported. The duration of remission after chemotherapy remains a vital prognostic factor for likelihood of response to future therapy.[18,19] This treatment offers a cure rate up to 50%.

Several studies have reported the importance of giving conventional chemotherapy before stem-cell transplant (SCT).

Table 95–5

Practical Information for ABVD and CHOP

Regimen	Drug Class	Pharmacokinetics	Unique Toxicities
ABVD			
Doxorubicin	Anthracycline	Hepatic metabolism[a]	Highly emetogenic Cardiomyopathy Maximum cumulative lifetime dose, 550 mg/m^2
Bleomycin	Antitumor antibiotic	Renal clearance[a]	Pulmonary fibrosis Maximum cumulative lifetime dose, 400 units
Vinblastine	Vinca alkaloid	CYP3A4/5 metabolism[a]	Neuropathy, constipation
Dacarbazine	Alkylating agent	Hepatic metabolism[a]	Myelosuppression
CHOP			
Cyclophosphamide	Alkylating agent	Prodrug; CYP3A4/5, 2D6	Highly emetogenic Hemorrhagic cystitis
Doxorubicin	Anthracycline	Hepatic metabolism	Cardiomyopathy
Vincristine	Vinca alkaloid	CYP3A4/5	Neuropathy, constipation
Prednisone	Corticosteroid	100% oral bioavailability	Hyperglycemia, osteopenia

[a] See dose adjustments (Chapter 88).

Patients who respond to second-line therapy (Deauville score of 1–3) should proceed to SCT. For those at high risk of relapse post SCT, 1 year of maintenance therapy with brentuximab vedotin may be considered.[20] The safety profile of autologous SCT continues to improve as refinements in supportive care advance. Current estimates of mortality from autologous SCT for HL are approximately 5%. Morbidity associated with preparative regimens in HL, aside from infectious and bleeding complications, includes pulmonary toxicity of bleomycin coupled with carmustine, inducing potentially fatal pulmonary pneumonitis. Patients who are not candidates for autologous SCT may receive brentuximab vedotin with or without standard salvage chemotherapy, such as etoposide, methylprednisolone, cytarabine, and cisplatin (ESHAP) or dexamethasone, cytarabine, and cisplatin (DHAP). Other regimens such as GVD (gemcitabine, vinorelbine, and pegylated liposomal doxorubicin), IGEV (ifosfamide, gemcitabine, and vinorelbine), and ICE (ifosfamide, carboplatin, etoposide) have also been effective. Other agents such as lenalidomide, bendamustine, and everolimus have also shown activity.[21] Programmed death 1 blocking monoclonal antibodies such as nivolumab and pembrolizumab are additional options for HL that have progressed after SCT with brentuximab maintenance or after three lines of systemic therapy including SCT.[22,23]

NONHODGKIN LYMPHOMA

EPIDEMIOLOGY AND ETIOLOGY

Approximately 81,560 cases of NHL were estimated to be diagnosed in the United States in 2021, with an estimated 20,720 deaths.[1] The median age for diagnosis is 50 years, although children and young adults may also be affected. The etiology of certain aggressive NHL subtypes is related to specific endemic geographic factors as well as exposure to various causative agents such as pathogens or environmental risks. Follicular or low-grade lymphoma is more common in the United States and Europe and relatively uncommon elsewhere. The incidence of Burkitt NHL is 7 cases per 100,000 people in Africa compared with 0.1 per 100,000 in the United States, likely related to malaria or EBV exposure. Human T-cell leukemia virus I, human herpesvirus 8, hepatitis C, *Helicobacter pylori*, and EBV have all been implicated in inducing NHL.[24] Due to the pathogen-related induction of NHL, immunocompromised patients are at increased risk of NHL. Environmental factors have been identified as contributing to the development of NHL. Certain occupations such as wood and forestry workers, butchers, exterminators, grain millers, machinists, mechanics, painters, printers, and industrial workers have a higher prevalence of disease. Industrial chemicals such as pesticides, herbicides, organic chemicals (eg, benzene), solvents, and wood preservatives are also associated with NHL.

PATHOPHYSIOLOGY

The pathophysiology of NHL is governed by numerous environmental and genetic events culminating with a monoclonal population of malignant lymphocytes. B cells represent the cells of origin in excess of 90% of cases. Cytogenetic abnormalities involving translocations of antigen receptor genes are prevalent in NHL. These include T-cell receptor genes in T-cell lymphomas and immunoglobulin genes in B-cell lymphomas. The principal defect appears to be an error in assembly of the regulatory gene segment of an antigen receptor gene, resulting in inappropriate binding to an oncogene. This results in dysregulation of cell growth and proliferation, leading to the malignant clone of lymphocytes. Oncogenes identified in different lymphomatous diseases include *MYC, BCL1, BCL2, BCL3, NFKB1* and *BCL6*.[25] Classic translocations for NHL include t(8;14) in Burkitt lymphoma, t(14;18) in follicular lymphomas, t(11;14) mantle-cell lymphoma, and t(11;18)/t(1;14) in mucosa-associated lymphoid tissue (MALT).

KEY CONCEPT Characterization of the morphology of lymphocytes, the reactivity of other cells in the lymph node, and architecture of the node are essential in obtaining a diagnosis and predicting disease course. The nodal presentation of NHL is divided into two main categories: follicular, corresponding to low-grade disease, and diffuse, corresponding to aggressive disease. A follicular disease pattern in the inspected lymph node is indicative of a more indolent or low-grade progression that has survival measured in years if left untreated. In contrast, a diffuse pattern of lymph node infiltration indicates highly aggressive disease, resulting in death within weeks to months if untreated. Follicular lymphoma (FL) is the most common indolent subtype, comprising 22% of NHL. Diffuse, large B-cell lymphoma (DLBCL) is the most common aggressive histology, comprising 31% of NHL. The cells of origin for FL tend to be more mature, nondividing lymphocytes, whereas aggressive NHL is derived from rapidly dividing lymphoid precursors. A unique feature of the biology of NHL is that follicular low-grade histologies can undergo further malignant transformation, transforming into a DLBCL population. This syndrome, also possible as a transition from chronic lymphocytic leukemia to an aggressive lymphoma, is called Richter transformation. Richter transformation involves multiple genetic events, including abnormalities of chromosomes 11 and 12 and tumor suppressor genes.[26]

The most commonly used classification system for lymphoid malignancies was proposed by the WHO. The WHO classification groups lymphomas based on cell of origin (B cell, T cell, NK cell) and considers each as its own unique disease entity (Table 95–1). Further description of tumors is based on cell characteristics such as aggressiveness, cell size, and proliferation.[5]

Prognostic factors present at diagnosis have been identified for NHL. Age, the presence of B symptoms, performance status, number of nodal and extranodal sites, LDH level, bulky disease (larger than 10 cm), advanced stage, and β_2-microglobulin concentration have been shown to be important prognostic features in NHL. The International Prognostic Index (IPI) is a predictive model for aggressive NHL to be treated with doxorubicin-containing chemotherapy regimens.[27] This index is used as a tool to identify patients who may benefit from a more intense treatment regimen. Tools to help identify patients with FL who appropriate for drug therapy include the Follicular Lymphoma International Prognostic Index (FLIPI)[28] and the GELF criteria (Table 95–6).[29]

TREATMENT OF NHL

Desired Outcome

NHL treatment depends primarily on histologic subtype (follicular low grade versus diffuse aggressive) and staging (local stage I/II versus advanced stage III/IV) to guide treatment with observation, chemotherapy, radiation, or chemotherapy and radiation. The Lugano modification of the Ann Arbor staging system for HL is also used in NHL.

Treatment goals depend on the specific subtype of NHL. For low-grade FL, the disease is considered to be incurable however

Table 95–6

Negative Prognostic Factors for NHL

International Prognostic Index—Diffuse, Aggressive NHL

Criteria	Risk Group	Number of Criteria
Age ≥ 60 years		
Stage III/IV disease	Low	0–1
Extranodal disease > 1 site	Low-intermediate	2
ECOG performance status 2 or greater	High-intermediate	3
Serum LDH > 1 × normal limit	High	4–5

Follicular Lymphoma International Prognostic Index

Criteria	Risk Group	Number of Criteria
Age ≥ 60 years		
Stage III/IV disease	Low	0–1
Hemoglobin < 12.0 g/dL (120 g/L; 7.45 mmol/L)	Intermediate	2
Serum LDH > 1 × normal limit	High	≥ 3
Number of nodal sites ≥ 5[a]		

GELF Criteria

Involvement of ≥ nodal sites, each with a diameter of ≥ 3 cm	Splenomegaly
Any nodal or extra nodal tumor mass with a diameter ≥ 7 cm	Pleural effusions or peritoneal ascites
Cytopenias (WBC < 1.0 × 10^9/L and/or platelets <100 × 10^9/L)	B-symptoms
Leukemia (>5 × 10^9/L malignant cells)	

[a]The nodal map used in the Follicular Lymphoma International Prognostic Index is different than the nodal map used in conventional staging.

long-term remission is possible. Many patients with FL are older than 60 years of age, making allogeneic SCT impractical due to high treatment-related mortality for older patients.

KEY CONCEPT The treatment goals for low-grade NHL include:

- Observation of the disease until the patient exhibits obvious progression that limits functional capacity or is life threatening
- Treatment that induces remission with manageable toxicity
- Judicious selection of treatment to avoid long-term toxicity
- Prevention of infectious complications

The intent of treatment for patients with aggressive histologies is cure. Some histologic subtypes exhibit a highly aggressive clinical course and are not considered to be curable. These patients are still treated with curative-intent chemotherapy or may be considered for a clinical trial.

Nonpharmacologic Therapy

For patients with low-grade FL, deferring initial therapy until progression of disease is a standard approach. The median survival time is 6 to 10 years. Some patients may be asymptomatic for several years after diagnosis, making observation a reasonable approach. Radiation therapy has a limited role in NHL relative to HL. NHL is more often a systemic disease, and radiation typically has been reserved for consolidation after chemotherapy in patients presenting with a large extranodal mass. However, ISRT without chemotherapy is the preferred treatment option for patients with nonbulky stage I/II FL.

For early-stage diffuse, aggressive NHL, combined-modality therapy, was tested versus a longer course of chemotherapy.[30] Five-year overall survival favored the CHOP–radiation arm (82% vs 72%). There was a trend toward increased toxicity, particularly hematologic and cardiac toxicity, in the prolonged CHOP alone arm. The results of this trial have established combined-modality therapy as first-line treatment for early-stage NHL.

Pharmacologic Therapy

▶ *Low-Grade FL*

Initial treatment of early stage (I/II) FL consists of ISRT. Patients with advanced disease (stage III/IV) and those with early stage bulky (larger than 7.5 cm tumor size) should be considered for systemic therapy. The decision to initiate drug therapy for FL should be based on patient-specific factors. The FLIPI and GELF models are used to help determine which patients should initiate therapy (Table 95–6**)**. Trials have shown that delaying the initiation of drug therapy until patients met at least one of the GELF criteria did not adversely affect survival and decreased overall chemotherapy exposure.[29]

Drug therapy for treatment of FL consists of chemoimmunotherapy. The chemotherapy component can include single-agent chemotherapy with bendamustine or combination regimens such as CHOP or CVP. In clinical trials, there has been no statistically significant difference in overall survival among the three regimens.[31] However, it is important to note that bendamustine-based regimens have been associated with opportunistic infections. Patients receiving bendamustine-based therapy should receive prophylactic therapy against *Pneumocytis jiroveci* pneumonia (PJP) and Varicella-Zoster virus (VZV). The immunotherapy component is a monoclonal antibody (MAB)-targeting CD20 on B-lymphocytes. Rituximab, a chimeric MAB, is the historical standard based on clinical trials. Recently, regimens containing obinutuzumab, another CD20-binding MAB, were compared to rituximab containing regimens. In the GALLIUM trial, obinutuzumab regimens resulted in improved progression-free survival compared to the same regimens combined with rituximab. However, response rates and overall survival were similar.[32] A recent regimen to be evaluated is rituximab with lenalidomide, a biological response modifier. This regimen demonstrated similar outcomes to the comparison chemotherapy/monoclonal antibody regimens.[33] These four acceptable regimens are outlined in Table 95–7. Following complete response, maintenance therapy with the MAB used should be considered. Rituximab was examined as maintenance therapy administered every 8 weeks for 2 years after rituximab chemoimmunotherapy. Compared with observation, rituximab increased 3-year progression-free survival (PFS).[34] Based on this evidence, the GALLIUM trial also included maintenance therapy in its treatment groups.

There are many treatment options available upon disease progression. At first progression, patients should change therapy to a different first-line regimen. Patients who are in relatively good health should be evaluated for stem-cell transplant upon achieving a second complete response.[35] Many new treatment options have demonstrated benefit for patients who have failed more than two therapies. The PI3K inhibitors idelalisib, copanlisib, and duvelisib have all demonstrated activity in these patients.[36] In patients who have failed at least two prior therapies, and whose disease has experienced transformation to diffuse large B-cell lymphoma,

Table 95–7

Chemotherapy Regimens for Low-Grade, Follicular NHL

CHEMOTHERAPY REGIMEN	ANTI-CD20 MAB
Bendamustine + CD20 MAB—Every 28 Days for 6 cycles Bendamustine 90 mg/m^2 IV days 1 and 2	Frequency and number of cycles match chemotherapy regimen MAB is used with
CVP+ CD20 MAB—Every 21 Days for 8 cycles Cyclophosphamide 750 mg/m^2 IV, day 1 Vincristine 1.4 mg/m^2 IV, day 1 Prednisone 40 mg/m^2 po daily, days 1–5 MAB only on cycles 7 and 8	**Rituximab** Rituximab 375 mg/m^2 IV day 1
CHOP+ CD20 MAB—Every 21 Days for 8 cycles Cyclophosphamide 750 mg/m^2 IV, day 1 Doxorubicin 50 mg/m^2 IV, day 1 Vincristine 1.4 mg/m^2 IV, day 1 Prednisone 100 mg/day po, days 1–5 MAB only on cycles 7 and 8	**Obinutuzumab** Obinutuzumab 1000 mg IV days 1, 8, 15 of cycle 1 day 1 only for subsequent cycles
Lenalidomide + Rituximab—Every 28 Days[a] Lenalidomide 20 mg po daily days 2–22 for at least 6 cycles Dose reduction to 10 mg daily upon achieving complete response Rituximab 375 mg/m^2 IV, days 1, 8, 15, and 22 of cycle 1 Day 1 only on cycles 2–6 Every 8 weeks for 12 additional cycles	

[a] Lenalidomide has not been studied in combination with obinutuzumab.

IV, intravenous; po, oral.

chimeric antigen receptor T-cell (CAR-T) therapy with axicabtagene ciloleucel or tisagenlecleucel have demonstrated efficacy.[37]

▶ *Diffuse, Aggressive NHL*

KEY CONCEPT The mainstay of therapy for diffuse, aggressive NHL, such as DLBCL, is anthracycline-based combination chemotherapy, generally consisting of four or more drugs. Therapy options for intermediate- and high-grade NHL generally are segregated between localized (stage I/II) and advanced (stage III/IV) disease. Combined-modality therapy with an abbreviated course of R-CHOP and local radiation is considered a standard of care for stage I/II disease. (Table 95-5)

The standard therapy for disseminated disease since the 1970s has been CHOP. This regimen conferred a response of 50% to 60%, with long-term survival of approximately 30%. The benefits of CHOP have been confirmed by multiple clinical trials including comparisons to regimens with more agents and varying schedules. None of these other options have improved on CHOP in patients with normal risk DLBCL.[38] There were no significant differences in response rate or overall survival between the groups and severe toxicity, and deaths were higher in the advanced-generation treatment regimens relative to CHOP, cementing CHOP as first-line chemotherapy in DLBCL.

Rituximab is also routinely used to treat DLBCL. A study randomized patients 60 to 80 years of age with newly diagnosed disease to either CHOP for eight cycles or CHOP plus rituximab (R-CHOP) for eight cycles.[39] Two-year follow-up showed rituximab improved CR (76% vs 63%) and median event-free survival (57% vs 38%) and long-term follow-up confirmed benefit with an improvement in 10-year survival (43% vs 27.6%). Similar findings have been reported in younger patients, making R-CHOP first-line therapy for advanced-stage DLBCL (Table 95–8).

KEY CONCEPT Rituximab is an effective treatment option for patients with various forms of NHL as long as patients are monitored appropriately. A limitation of rituximab is severe, potentially fatal infusion-related reactions. Deaths have been reported resulting from the profound hypotension and circulatory collapse, particularly with the first dose. The package labeling recommends premedication with acetaminophen and diphenhydramine before each infusion. The initial infusion should be given slowly, at 50 mg/hour and may be increased as tolerated to a maximum of 400 mg/hour. In the absence of infusion reactions, subsequent doses may be started at a higher rate and titrated more aggressively. Other associated toxicities of rituximab include fever, chills, headache, asthenia, nausea, vomiting, angioedema, bronchospasm, and skin reactions.

Despite advances in the treatment of NHL, relapse remains a concern. Salvage therapy plays a major role in the attempt to treat recurrence. Multiple drug regimens such as ESHAP and DHAP can induce a CR, but long-term cure with these regimens is less than 10%. When salvage regimens are used, rituximab is frequently added to the regimen. Further salvage therapy can induce remissions with subsequent relapses; however, the chance for a CR is further diminished.

High-dose chemotherapy with autologous SCT has been studied as an alternative to standard dose regimens in the setting of first relapse.[40] The best-studied indication for SCT is for patients with intermediate- or high-grade disease that fails to respond to first-line therapy. Modern results from autologous SCT have demonstrated a 5-year disease-free survival rate of 48% and overall survival at 5 years of 63%.[41] The procedure-related mortality rate has ranged from 5% to 10% in published reports. However, with improvements in SCT techniques and better supportive care, the mortality rate continues to decline. The role of allogeneic SCT in this setting is limited because of donor availability, older age of patients, and the high treatment-related morbidity and mortality. Outcomes between autologous and allogeneic transplant appear similar.

CAR-T therapy should be considered in patients with DLBCL who have failed at least two prior regimens. Both axicabtagene

Table 95–8

Treatment Regimens for Diffuse, Aggressive NHL

R-CHOP—Every 21 Days[a]
EPOCH-R—Every 21 Days[b]
Rituximab 375 mg/m^2 IV, day 1
Etoposide 50 mg/m^2/day CIVI, days 1–4
Prednisone 60 mg/m^2/day po, days 1–5
Vincristine 0.4 mg/m^2/day CIVI, days 1–4
Cyclophosphamide 750 mg/m^2 IV, day 5
Doxorubicin 10 mg/m^2/day CIVI, days 1–4

R-CNOP-Rituximab—Every 21 Days[c]
Rituximab 375 mg/m^2 IV, day 1
Cyclophosphamide 750 mg/m^2 IV, day 1
Mitoxantrone 10 mg/m^2 IV, day 1
Vincristine 1.4 mg/m^2 IV, day 1
Prednisone 100 mg/day po, days 1–5

R-Hyper-CVAD
Part A: The following drugs given on course 1, 3, 5, and 7
Rituximab 375 mg/m^2 IV, day 1
Cyclophosphamide 300 mg/m^2 IV every 12 hours, days 1–3 (with mesna)
Doxorubicin 50 mg/m^2 IV, day 1
Vincristine 1.4 mg/m^2 IV, days 1, 11
Dexamethasone 40 mg/day po, days 1–4 and 11–14
Methotrexate 15 mg intrathecal, day 2
Cytarabine 30 mg intrathecal, day 2
Hydrocortisone 15 mg intrathecal, day 2
Part B: The following drugs are given on courses 2, 4, 6, and 8
Rituximab 375 mg/m^2 IV, day 1
Methotrexate 1000 mg/m^2 IV over 24 hours, day 1
Cytarabine 3000 mg/m^2 IV every 12 hours, days 2 and 3
Leucovorin 25 mg IV × 1; then 25 mg po every 6 hours for seven doses
Methotrexate 15 mg intrathecal, day 2

Bendamustine/Rituximab—Every 28 Days[a]
ESHAP
Etoposide 40 mg/m^2 IV per day continuous infusion, days 1–4
Cisplatin 25 mg/m^2 IV per day continuous infusion, days 1–4
Cytarabine 2000 mg/m^2 IV × 1, day 5
Methylprednisone 250 mg IV every 12 hours, days 1–4

DHAP
Dexamethasone 40 mg po or IV daily, days 1–4
Cisplatin 100 mg/m^2 IV continuous infusion, day 1
Cytarabine 2000 mg/m^2 IV every 12 hours for two doses on day 2

ICE
Etoposide 100 mg/m^2 IV daily, days 1–3
Carboplatin AUC 5 (maximum dose, 800 mg) IV, day 2
Ifosfamide 5000 mg/m^2 IV continuous infusion × 1 on day 2 (with 100% replacement with Mesna)

[a] Refer to Table 95–8 for regimen.

[b] Doses listed are for cycle 1 only. Subsequent cycle dosing based on degree of myelosuppression experienced.

[c] Data are limited, use only for patients who are unable to receive an anthracycline.

AUC, area under the curve; CIVI, continuous intravenous infusion; IV, intravenous; po, oral.

ciloleucel and tisagenlecleucel have demonstrated significant benefit in patients who have progressed despite multiple prior therapies, achieving a complete response in 40% and 49% of patients.[37] CAR-T therapy carries significant risk with life-threatening cytokine-release syndrome and neurologic toxicity. Because of the potential toxicities, CAR-T therapy should only be given in specially designated treatment centers.

▶ *Special Populations*

There are histologic subtypes of diffuse, aggressive NHL which are less responsive to treatment with conventional regimens such as R-CHOP. Burkitt lymphoma, lymphoblastic lymphoma, mantle-cell lymphoma, primary mediastinal large B-cell lymphoma, and primary CNS lymphoma are examples of disease that benefit from more intensive therapy. Regimens such as R-hyper-CVAD, which alternate cycles of rituximab, hyperfractionated cyclophosphamide, doxorubicin, vincristine, and dexamethasone with rituximab, high-dose cytarabine and methotrexate,[42,43] or EPOCH-R, which contains etoposide, prednisone, vincristine, cyclophosphamide, doxorubicin, and rituximab should be considered alternatives to R-CHOP.

The presence of *MYC* gene rearrangement in addition to either *BCL2* or *BCL6* gene rearrangements is known as double-hit lymphoma (DHL) and can occur in patients with DLBCL or other high-grade lymphomas. These lymphomas are highly aggressive and have inferior response to R-CHOP.[44] Aggressive chemotherapy regimens such as dose-adjusted EPOCH-R have been shown to superior outcomes and should be used in the treatment of DHL.[45]

Patients with CNS NHL have disease that is poorly responsive to therapy because of inadequate penetration of standard doses of chemotherapy across the blood–brain barrier. High-dose methotrexate, ranging from 2500 to 8000 mg/m^2, is a mainstay of therapy. Treatment may also include intrathecal chemotherapy. Antineoplastics that are commonly used intrathecally include methotrexate, cytarabine (conventional formulation and liposomal products), and corticosteroids.

The recognition of *H. pylori* colonization and MALT has spurred the more aggressive treatment of this organism with antibiotics. In patients with localized disease, aggressive, combination therapy for *H. pylori* has been shown to induce MALT remission. Patients with advanced disease may require chemotherapy with R-CHOP.

Patient Encounter Part 2: Treatment Selection

Complete evaluation revealed stage IV classic Hodgkin lymphoma that is positive for CD15, CD30, and negative for CD20. Therapy is scheduled to begin immediately.

What therapy (or therapies) is (are) most appropriate for this patient?

At this time, is this patient an appropriate candidate for stem-cell transplant?

What other information (eg, laboratory studies, diagnostic tests) is needed prior to initiating chemotherapy?

Patient Encounter Part 3: Creating a Care Plan

Based on the information presented, create a care plan for this patient, including the goals of therapy, antineoplastic therapy plan, and necessary supportive care.

Patients with HIV-related lymphoma represent a therapeutic dilemma considering many have high-grade NHL. A common presentation includes extranodal disease, frequently in the GI tract, CNS, or bone marrow. Because of the aggressive nature of HIV-related lymphoma, aggressive chemotherapy regimens such as Hyper-CVAD and EPOCH are recommended. Antiretroviral therapy is important to improving patients' ability to tolerate chemotherapy and should be initiated before chemotherapy. The use of CSFs to promote white blood cell counts is also recommended. Rituximab should be added to chemotherapy for CD20-positive lymphomas in patients with an adequate CD4 count.

▶ *Supportive Care*

Due to the high sensitivity to therapy of many lymphomas, most patients treated for lymphoma with chemotherapy or radiation notice a regression of palpable lymphadenopathy within days. This also necessitates implementation of tumor lysis syndrome precautions with aggressive intravenous hydration and allopurinol, particularly if the patient has a large tumor burden. Rasburicase should be considered for patients with moderate-to-high tumor burdens.

In addition to prophylaxis for PJP and VZV in patients receiving bendamustine, patients with lymphoma must be aware of potential infectious complications from their therapy. Combination regimens for both HL and NHL are associated with rates of severe leukopenia and/or neutropenia ranging from 20% to 100% of patients. Consideration must be given to supportive care with prophylactic colony stimulating factors or antibiotics. Additionally, the use of CD20-targeting monoclonal antibodies has been associated with reactivation of hepatitis B virus (HBV).[46] Prophylactic therapy should be initiated for all patients who test positive for HBV surface antigen (HBsAg) and patients who test positive for HBV core antibody (HBcAb) and who test negative for HBV surface antibody (HBsAb). Entecavir is preferred over lamivudine due to concerns of viral resistance.[47]

OUTCOME EVALUATION

Treatment response in lymphomas is measured using the response evaluation criteria in solid tumors (RECIST), a uniform criterion assessing tumor response developed by the National Cancer Institute. Lymphomas may have residual masses after completion of treatment, adding to the difficulty in establishing a definitive remission from treatment. Historically, imaging scans using positron emission tomography or computed tomography have been

Patient Care Process

Collect Information:

- Take a thorough medication history with particular attention to nonprescription or herbal medications.
- Review medical history with an emphasis on identifying causative factors of lymphoma and preexisting medical conditions that can affect chemotherapy.

Assess the Information:

- Evaluate home medications to identify any potential drug interactions with chemotherapy.
- Review findings of diagnostic tests including laboratory values, imaging results, pathology results, cancer diagnosis, and genetic profile of the malignancy.
- Determine the stage and prognostic index for the patient.
- Before initiation of treatment, assess patient for risk of tumor lysis syndrome.

Develop a Care Plan:

- Identify the optimal treatment regimen for the patient incorporating diagnosis, stage, and prognostic indicators (Tables 95–4, 95–7, 95–8)
- Verify chemotherapy regimen doses with a standardized reference and assess for dose adjustment based on height, weight, and body surface area and organ dysfunction (renal or hepatic).
- Assess appropriateness of supportive care for the chemotherapy regimens including need for prophylactic antiemetics and use of colony-stimulating factors.

Implement the Care Plan:

- Provide patient education regarding common toxicities associated with chemotherapy such as nausea/vomiting, mucositis, myelosuppression, and alopecia.
- For doxorubicin-containing regimens, maintain records of the cumulative doxorubicin dosage received by the patient to monitor for cardiac toxicity risk.
- For bleomycin-containing regimens, maintain records of the cumulative bleomycin dosage received by the patient to monitor for pulmonary fibrosis.
- Educate patients regarding the short- and long-term complications associated with radiation therapy.
- Provide contact numbers for patient in the event of a fever and a response plan if the patient is considered to be at risk for neutropenic fever.

Follow-up: Monitor and Evaluate:

- Schedule regulatory laboratory tests including complete blood count and blood chemistries to monitor for chemotherapy toxicities and tumor lysis syndrome.
- Use RECIST criteria to determine patient's response to therapy by reviewing PET-CT scan following completion of therapy.
- Develop a plan to monitor for long-term complications of chemotherapy such as cardiotoxicity and secondary malignancies.

used to evaluate patient with lymphomas. Now, PET combined with CT is recommended to evaluate patients with lymphoma for staging as well as for response assessment.[48]

Long-term follow-up monitors patients for continued disease remission with careful examination of the original areas of involvement and repeated follow-up imaging. Patients also require long-term monitoring for toxicities of their treatment.

Advances in the treatment of lymphoma have increased the number of long-term survivors. Identification of long-term complications of lymphoma therapy is vital to patient follow-up and may influence treatment decisions in newly diagnosed patients. Outcomes associated with the treatment of HL make up the majority of data. However, advances in NHL treatment have provided more information regarding long-term toxicities. Two leading causes of death associated with lymphoma treatment are secondary malignancies and cardiovascular disease. The use of combined modality of irradiation with doxorubicin-based therapy has been reported to increase the risk of cardiac dysfunction. Treatment-related pulmonary toxicity, hypothyroidism, and infertility have been associated with lymphoma therapy as well (Table 95-5). Lymphoma survivors have an increased risk for developing myelodysplasia, acute myelogenous leukemia, and various solid tumors.[49]

Abbreviations Introduced in This Chapter

BCL1	Important in the regulation of mitosis
BCL2	A regulator of apoptosis
BCK3	A regulator of nuclear transcription factor
BCL6	Regulates cell differentiation
MYC	Regulator of gene transcription
ABVD	Doxorubicin, bleomycin, vinblastine, and dacarbazine
AVD	Doxorubicin, vinblastine, and dacarbazine
BEACOPP	Bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, prednisone
CHOP	Cyclophosphamide, doxorubicin, vincristine, and prednisone
CVP	Cyclophosphamide, vincristine, prednisone
CT	Computed tomography
CSFs	Colony-stimulating factors
CVP	Cyclophosphamide, vincristine, and prednisone
DHL	Double-hit lymphoma
DLBCL	Diffuse large B-cell lymphoma
EBV	Epstein-Barr virus
FL	Follicular lymphoma
FLIPI	Follicular lymphoma international prognostic index
GELF	Groupe d'Etude des lymphomes folliculaires
HL	Hodgkin lymphoma
INRT	Involved-node radiation therapy
IPI	International Prognostic Index
IPS	International Prognostic Score
ISRT	Involved-site radiation therapy
LDH	Lactate dehydrogenase
MAB	Monoclonal antibody
MALT	Mucosa-associated lymphoid tissue
MOPP	Mechlorethamine, vincristine, procarbazine, and prednisone
NHL	Non-Hodgkin lymphoma
PET	Positron emission tomography
PFS	Progression-free survival
RECIST	Response evaluation criteria in solid tumors
RS	Reed–Sternberg
SCT	Stem-cell transplantation

Acute Leukemias

Nancy H. Heideman and Dulcinea Quintana

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify the risk factors associated with a poor outcome for the acute leukemias.
2. Explain the importance of minimal residual disease (MRD) and its implication on early bone marrow relapse.
3. Explain the role of induction, consolidation, and maintenance phases for acute lymphocytic leukemia (ALL).
4. Define the role of central nervous system preventive therapy for the treatment of acute lymphocytic leukemia.
5. Identify new treatment options available based on specific biologic targets for the treatment of adult acute leukemias.
6. Describe the clinical presentation and diagnosis of acute myelogenous leukemia (AML).
7. Identify underlying considerations that would determine the most appropriate chemotherapeutic regimens for both acute lymphocytic leukemia and acute myelogenous leukemia.
8. Recognize the treatment complications associated with the therapy for acute leukemias.
9. Describe the late effects associated with the treatment of long-term survivors of acute leukemias.

INTRODUCTION

KEY CONCEPT The acute leukemias are hematologic malignancies of bone marrow precursors characterized by excessive production of immature hematopoietic cells. This proliferation of "blast" cells eventually replaces normal bone marrow and leads to the failure of normal hematopoiesis and the appearance in peripheral blood as well as infiltration of other organs. These blast cells proliferate in the marrow and inhibit normal cellular elements, resulting in anemia, neutropenia, and thrombocytopenia. Leukemia also may infiltrate other organs, including the liver, spleen, bone, skin, lymph nodes, testis, and central nervous system (CNS). Virtually anywhere there is blood flow, the potential for extramedullary (outside the bone marrow) leukemia exists.

KEY CONCEPT Acute leukemias are classified according to their cell of origin. Acute lymphocytic leukemia (ALL) arises from the lymphoid precursors. Acute myelogenous leukemia (AML) arises from the myeloid or megakaryocytic precursors. As a result of clinical trials defining various prognostic (risk) factors that helped guide treatment modifications, the outcomes of acute leukemias, especially pediatric ALL, have improved dramatically over the past several decades.[1] Risk-based treatment strategies that consider multiple phenotypic and biological risk factors and attempt to match the aggressiveness of therapy with the presumed risk of relapse and death are now the standard of care. Despite the overall success in treating patients with acute leukemias, further advances are needed in the treatment of relapsed ALL.[1]

EPIDEMIOLOGY AND ETIOLOGY

Epidemiology

Leukemia is a relatively uncommon disease. The current overall age-adjusted annual incidence of acute leukemia in the United States has remained relatively stable at 13.1 per 100,000 in children and 1–2 per 100,000 in adults. In 2021, it is estimated there will be 61,090 new cases of leukemia, or 3.2% of all new cancer cases.[2]

In the pediatric population, leukemia is a common cancer, accounting for almost one-third of all childhood malignancies. ALL accounts for 75% to 80% of all cases of childhood leukemia, whereas AML accounts for no more than 20%. Males generally are affected more often than females in all but the infant age-group, and its incidence is higher in White individuals than among other racial groups.

The incidence of AML in children is bimodal. Incidence peaks in infants less than 1 year, decreases steadily then increases again for ages 10–14 years.[3] The average age of diagnosis for AML is about 65 years and a result of an increasing incidence of AML with age.[4]

Etiology

The cause of acute leukemias is unknown; multiple influences related to genetics, socioeconomics, infection, environment, hematopoietic development, and chance may play a role. Table 96–1 lists the major conditions associated with acute

Table 96–1

Clinical Conditions Associated With an Increased Frequency of Acute Leukemias

Drugs

leukemias. In most cases, however, there is no identifiable cause of the leukemia.

Although leukemia is rarely a hereditary disease, some genetic associations are evident. For example, among identical twins, the concordance for ALL in the initially unaffected twin is 20% to 25% within 1 year. Although the incidence in fraternal twins is much less, there is still a fourfold increase in the risk of leukemia in the initially unaffected twin compared with the healthy population. One explanation for this association may be a shared placental circulation, which allows for transmission of disease from one twin to the other. Additionally, leukemia has an increased incidence in several chromosomally abnormal populations. For example, patients with Down syndrome have 20 times increased risk of developing leukemia compared with the rest of the population.

Exposure to environmental agents, such as agricultural chemicals, pesticides, and radiation, is associated with leukemia, but none is conclusively related to the development of leukemia. An increased frequency of ALL is associated with higher socioeconomic status. It is postulated that less social contact in early infancy and, thus, a late exposure to some common infectious agents may have some impact.[1]

Risk factors for the development of AML include exposure to environmental toxins, Hispanic ethnicity, and genetics.[5] Also of concern is the increased prevalence of AML as a secondary malignancy, resulting from chemotherapy and radiation treatment for other cancers. Alkylating agents, such as ifosfamide and cyclophosphamide, and topoisomerase inhibitors, such as etoposide, are linked to an increased risk of AML and myelodysplastic syndrome (MDS).[4]

PATHOPHYSIOLOGY

Hematopoiesis is defined as the development and maturation of blood cells and their precursors. In utero, hematopoiesis may occur in the liver, spleen, and bone marrow; after birth, this process occurs exclusively in the bone marrow. All blood cells are generated from a common hematopoietic precursor or stem cell. These stem cells are self-renewing and pluripotent and, thus, are able to commit to any one of the different lines of maturation that give rise to platelet-producing megakaryocytes, lymphoid, erythroid, and myeloid cells. The myeloid cell line produces monocytes, basophils, neutrophils, and eosinophils, whereas the lymphoid stem cell differentiates to form circulating B and T lymphocytes, natural killer (NK) cells, and dendritic cells. In contrast to the ordered development of normal cells, the development of leukemia seems to represent an arrest in differentiation at an early phase in the continuum of stem cell to mature cell.

Both AML and ALL are thought to arise from clonal expansion of these "arrested" cells. As these cells expand, they acquire one and often more chromosomal aberrations, including translocations, inversions, deletions, point mutations, and amplifications. The translocation t(12;21) or *TEL–AML1* is found in approximately 25% of cases of pediatric ALL and is associated with a favorable prognosis.[1] This translocation is uncommon in adults. Another example is the t(9;22) translocation (Philadelphia chromosome, Ph^+), which results in the *BCR–ABL* fusion protein. This translocation produces a novel kinase that leads to uncontrolled proliferation, survival, and self-renewal of cells. It is uncommon in childhood ALL and commonly found in adult ALL, especially in older patients.

Patients with MDS or AML as a secondary neoplasm are often characterized by having had prior alkylator- or etoposide-based chemotherapy. Patients who have received treatment for Hodgkin disease or solid tumors are most at risk for this problem because they often treated with these agents. Patients with MDS have an abnormal bone marrow and a variety of cytopenias involving one or more of their marrow cell lines. They are at high risk of converting to overt leukemia over time. A variety of complex cytogenetic findings and monosomies of chromosome 5 or 7, and 11q deletions are often present in this population.[6]

Leukemia Classification

Classification methods for leukemia have evolved from simple schemes that were largely phenotypic and considered only age, gender, white blood cell (WBC) count, and blast morphology to now-complex methods that include biological features such as cell-surface receptors, DNA content (ploidy; more or less than normal chromosomal DNA content), and a variety of cytogenetic abnormalities.

For all newly diagnosed patients with leukemia, an aspirate of the liquid marrow and a bone marrow core biopsy are obtained. Analysis of the leukemic cell-surface markers (immunophenotyping) establishes three types of ALL, pre-B, mature B, and T-cell precursor ALL. There are eight subtypes of AML (M0 to M7) as classified by the French–American–British (FAB) scheme. The World Health Organization identifies specific entities within the diagnosis of AML based on a combination of karyotypic and molecular mutations (Tables 96–2 and 96–3).

Immunophenotyping by flow cytometry has taken on an increasingly important role in the diagnosis of leukemia. Owing to the ease of application, sensitivity, and quantifiable results, flow cytometry is the preferred method for leukemic lineage as well as prognostic assignment.[7] This approach takes advantage of

Table 96–2

Morphologic (FAB) Classification of AML

Subtype			Frequency of FAB Subtype	
		Adults (%)	Children Older Than 2 Years (%)	Children Younger Than 2 Years (%)
M0	Acute myeloblastic leukemia without maturation	5	Low	Low
M1	Acute myeloblastic leukemia with minimal maturation	15	17	7
M2	Acute myeloblastic leukemia with maturation	25		27
M3	Acute promyelocytic leukemia	10		5
M4	Acute myelomonocytic leukemia	20	30	26
M5a	Acute monoblastic leukemia, poorly differentiated	10	52	26
M5b	Acute monoblastic leukemia, well differentiated	5		
M6	Acute erythroleukemia	5		2
M7	Acute megakaryoblastic leukemia	5		7

FAB, French–American–British.

the development of diagnostic monoclonal antibodies (MABs) to many cell-surface antigens that are differentially expressed during hematopoietic differentiation. The antigens are referred to as antibody cluster determinants (CDs) that define cells at various stages of development and can easily separate ALL from AML and T cell from pre–B-cell ALL.[7,8] The combined approach of flow cytometric identification and cytogenetic DNA content, much of which is also revealed by flow cytometry and fluorescent in situ hybridization (FISH; microscopic, fluorescence identification of chromosomal features), has facilitated diagnosis and delineation of specific subtypes of the acute leukemias. Common immunophenotypic markers seen in AML and ALL are provided in Table 96–4.

Table 96–3

WHO Classification of AML and Related Neoplasms

AML with recurrent genetic abnormalities:
AML with t(8;21)(q22;q22); *RUNX1-RUNX1T1*
AML with inv(16)(p13.1q22) or t(16;16)(p13.1;q22); *CBEB-MYH11*
Acute promyelocytic leukemia (APL) with t(15;17)(q22;q12); *PML-RARA*
AML with t(9;11)(p22;q23); *MLLT3-MLL*
AML with t(6;9)(p23;q34); *DEK-NUP214*
AML with inv(3)(q21q26.2) or t(3;3)(q21;q26.2); *RPN1-EVI1*
AML (megakaryoblastic) with t(1;22)(p13;q13); *RBM15-MKL1*
Provisional entity: AML with mutated NPM1
Provisional entity: AML with mutated CEBPA

AML with myelodysplasia–related change

Therapy-related myeloid neoplasms

AML, not otherwise specified:
Undifferentiated AML (M0)
AML with minimal differentiation (M1)
AML without maturation (M2)
AML with maturation (M2)
Acute myelomonocytic leukemia (M3)
Acute monoblastic/monocytic leukemia (M4)
Acute erythroid leukemia (M5)
Pure erythroid leukemia (M6)
Erythroleukemia, erythroid/myeloid (M6)
Acute megakaryoblastic leukemia (M7)

Acute basophilic leukemia

Acute panmyelosis with myelofibrosis

Myeloid sarcoma

Myeloid proliferations related to Down syndrome:
Transient abnormal myelopoiesis
Myeloid leukemia associated with Down syndrome

Blastic plasmacytoid dendritic cell neoplasm

Prognostic Factors

KEY CONCEPT The goal of treatment is to match treatment to risk and minimize overtreatment or undertreatment. Patients with leukemia are categorized based on clinical and biological features that mirror their risk of relapse. Risk assessment is an important factor in the selection of treatment. Age, WBC, leukemic cell-surface markers, DNA content, and specific cytogenetic abnormalities predict response to therapy and are used to assign risk and associated treatment.[5] On the basis of these prognostic variables, patients are assigned to standard-, high-, or very high–risk groups that determine the aggressiveness of treatment. Much of the success has been driven by changes in risk stratification, including therapy for higher risk groups, deescalation for lower risk groups, and more recently novel targeted therapies.[1]

▶ *Prognostic Factors in ALL*

In both children and adults with ALL, clinical trials have identified several risk factors that correlate with outcome (Table 96–5).

Table 96–4

Common Immunophenotypes in Acute Leukemia

Leukemia	Common Immunophenotypes
AML	CD13, CD15, CD33, CD14, CD64, CD65, C-KIT
B-cell ALL	CD19, CD20, CD10, CD22, CD79a
T-cell ALL	CD2, CD3, CD4, CD5, CD7, CD1a, CD8

ALL, acute lymphoblastic leukemia; AML, acute myeloid leukemia; CD, cluster determinant.

Table 96–5

Prognostic Factors in ALL

	Risk for Leukemic Relapse	
Factor	**Standard/Low**	**High**
Age at diagnosis	1 to < 10 years of age	>10 years of age; < 1 year of age
Immunologic phenotype	B ALL	T ALL
WBC count at diagnosis	$< 50 \times 10^3/mm^3$ ($50 \times 10^9/L$)	$> 50 \times 10^3/mm^3$ ($50 \times 10^9/L$)
Cytogenetics	ETV6-RUNX1, t(12;21), trisomy 4, 10, 17	t(9;22); t(4;11); t(17;19), iAmp21, Ph-like
Ploidy	Hyperdiploidy	Hypodiploidy, near haploid
CNS leukemia	Absent	Present
MRD at end of induction	< 0.01%	> 0.01%

WBC, white blood cell.

Adapted from Vrooman LM, Silverman LB. Treatment of childhood acute lymphoblastic leukemia: prognostic factors and clinical advances. Curr Hematol Malig Rep. 2016;11:385–394.

Prognostic features include age, WBC count, cytogenetic abnormalities, ploidy (DNA content), leukemic cell immunophenotype, and degree of initial response to therapy, and minimal residual disease (MRD; the degree of subclinical disease remaining at various times after starting treatment).[5] When these factors are combined, they predict groups of patients with varying degrees of risk for treatment failure.

The importance of age is evident in both children and adults. Children younger than 1 year or older than 10 years of age have a poorer outcome than others. Likewise, in adults, there is a steady decline in the rate of survival with increasing age. Patients greater than 60 years have particularly poor outcomes with only 10% to 15% long-term survival. Older patients tend to have disease with unfavorable biology, more medical comorbidities, and inability to tolerate standard chemotherapy.[9]

Similar to age, the WBC count at presentation is a reliable indicator of complete response (CR) rate and outcome. The WBC count is indicative of tumor burden, although the underlying biological mechanisms that account for the unfavorable outcomes associated with an elevated WBC count are unclear. Patients with WBC counts of less than $50 \times 10^3/mm^3$ ($50 \times 10^9/L$) are considered being at standard risk and have a better outcome than those with higher WBC counts at presentation, which is associated with higher risk of treatment failure (see Table 96–5).

Specific chromosomal abnormalities in leukemic cells also possess prognostic significance. Blast cells with a translocation of parts of chromosome 12 and 21 (the *TEL–AML1* fusion) or trisomies of 4, 10, and 17 are considered to have favorable genetic features. The presence of the Philadelphia chromosome (Ph^+), the result of a specific translocation between chromosome 9 and 22, t(9;22)(q34;q11.2), is a high-risk feature, which is present in about 3% of children but is much more common in adults with ALL.[9] This translocation results in a novel tyrosine kinase that drives cell proliferation. A variant with a similar expression profile to Ph+ ALL but without the BCR-ABL rearrangement has been identified.[10] This so-called Ph-like ALL occurs in approximately

Patient Encounter 1, Part 1

Your patient is a 22-year-old man who presents to the emergency department with a chief complaint of progressive shortness of breath for the past 10 days. Patient endorses night sweats, fatigue, and an unintentional weight loss of about 10 pounds. He has not had any recent contact with anyone who is sick.

Physical Exam:

General appearance—well-developed, well-nourished man in no acute distress

HEENT—normocephalic, atraumatic neck; neck supple, nontender, no lymphadenopathy.

Lungs—decreased breath sounds left >right; nonlabored respiration on oxygen 4L/min via nasal cannula

Heart—normal rate and regular rhythm

Abdomen—soft nontender, nondistended normal bowel sounds

Musculoskeletal—normal range of motion, no tenderness or swelling

Skin—warm, dry, and pink no rashes or lesions

Neurologic awake alert and oriented × 3

Genitourinary—no hematuria or CVA tenderness

Vital signs and uric acid within normal limits, weight 77 kg, and height 170 cm

CT scan chest, abdomen, and pelvis at an outside hospital demonstrate a mass in the anterior mediastinum associated with encasement of the adjacent vascular structures. There is a large left-sided pleural effusion. Chest tube placed at outside hospital. Disease involves the liver and bilateral kidneys.

MRI of brain revealed no acute intracranial abnormalities.

Mediastinal mass core biopsy: consistent with T-cell lymphoblastic leukemia

CBC: WBC $25 \times 10^9/L$ (reference 4–10); platelet count $146 \times 10^9/L$ (reference range 150–400); hemoglobin 10 g/dL (100 g/L, 6.21 mm/L; normal 11.7 to 15.7 g/dL, 117 to 150 g/L, 7.3 to 9.7 mmol/L), and hematocrit 30% (0.3; normal 35% to 47%, or 0.35 to 0.47) bone marrow biopsy and aspirate reveals 80 % blasts (normal 0)

Chemistries and uric acid are within normal limit, and CSF leukemic screen is negative

The patient is admitted to the inpatient hematology-oncology service at the hospital. He is started on a pediatric research protocol consisting of a four-drug induction with vincristine, daunorubicin, pegasparaginase, and prednisone. Patient also received 1 dose of intrathecal cytarabine for CSF prophylaxis.

What is the purpose of a 4 drug induction?

15% of pediatric patients and 20% to 25% of adult patients with B-cell ALL. This mutation also confers a poor prognosis.[11]

Among children younger than 1 year of age, as many as 70% possess a poor prognostic genotype represented by the presence of the *MLL* (11q23) gene rearrangement. This finding is rare among older patients. Leukemias with the *MLL* gene rearrangement are highly resistant to the key antileukemic agents such as glucocorticoids and L-asparaginase.[1,12]

The DNA content of blast cells, hyper-, hypo-, or diploid, corresponding to increased, decreased, or normal chromosome numbers, is also a prognostic factor. Lower risk patients with hyperdiploidy (more than 50 chromosomes per leukemic cell) generally include approximately 25% of children who have B-cell lineage ALL.[9] These children are between the ages of 1 and 9 years, but the higher risk patients with normal diploidy (50 chromosomes) generally are older. Hypodiploid ALL with less than 44 chromosomes occurs in 1% to 5% of pediatric patients with ALL and is an independent risk factor for poor prognosis with declining prognosis with decreased chromosome number.[9]

Patients with cell-surface markers indicating that the blasts are early in the B-cell lineage (CD markers) are considered favorable and standard risk, whereas those with mature B- and T-cell blasts are considered high risk. T-cell ALL is found in approximately 15% of childhood ALL. Compared with B-lineage ALL, T-cell ALL is relatively resistant to different classes of drugs, including methotrexate and cytarabine.[13]

Patients completing induction treatment and in apparent remission still harbor malignant cells in their bone marrow even though they appear disease free by peripheral blood and bone marrow morphology. Assuming that most patients present with about a 10^{11} leukemic cell burden at diagnosis, at least 10^9 cells remain after initial treatment. These residual leukemic cells are below the limits of detection using standard morphologic examination. Measurement of this population of cells has become an increasingly significant prognostic factor and a determinant of the aggressiveness of postinduction therapy. Through flow cytometric analysis and polymerase chain reaction, it is possible to detect one leukemic cell among 10^6 normal cells, representing 1000-fold greater sensitivity than morphologic examination.[9]

Patient Encounter 1, Part 2

Your patient was admitted for a line infection on day 18. Cefepime was started. Chest tube was removed after effusion was deemed clear. Chemistries and fibrinogen were obtained. All labs were within normal limits. The patient's fibrinogen was 95 mg/dL (normal 200 to 400 mg/dl or 11.1 to 22.2 mmol/L)

Which agent is responsible for the low fibrinogen?

What is the mechanism by which this agent causes low fibrinogen?

Patient received 7 days of broad-spectrum antibiotic. During this time, he also received his day 22 chemotherapy that included vincristine, daunorubicin, and continued prednisone. Upon discharge, the patient is complaining of significant tingling in his hands and feet.

Which of the following agents is responsible for causing peripheral neuropathy?

a. Prednisone
b. Vincristine
c. Daunorubicin
d. Intrathecal cytarabine

Patient Encounter 1, Part 3

On day 29, patient has a bone marrow aspirate to determine minimal residual disease (MRD) and an intrathecal methotrexate for CNS prophylaxis. The MRD was less than 0.01 %.

What is the significance of an MRD less than 0.01%?

KEY CONCEPT Minimal residual disease (MRD) is a quantitative assessment of subclinical remnant of leukemic burden remaining at the end of the initial phase of treatment (induction) when a patient may appear to be in a complete morphologic remission. This measure has become one of the strongest predictors of outcome for patients with acute leukemia. The elimination of MRD is a principal objective of postinduction leukemia therapy. Several studies in children, in whom ALL is common, have evaluated disease levels at the end of induction and correlated these values with event-free survival (EFS). For a patient with detectable MRD less than 0.01% at the end of induction, EFS is approximately 90% at 3 years. Conversely, a patient with high MRD (greater than 1%) has a 3-year EFS of only 30%.[9] Assessment of MRD is also emerging as an important indicator of disease recurrence in the adult population and in patients with AML.

▶ *Prognostic Factors in AML*

The major prognostic factors in newly diagnosed AML are age, subtype, molecular and cytogenetic changes, and performance status.[14]

Older adults with AML (older than 60 years), compared with younger patients with the same disease, have a dismal prognosis and represent a distinct population in terms of disease biology, treatment-related complications, and overall survival (OS). Older patients with secondary AML have an even poorer prognosis. Older patients also have a higher incidence of unfavorable chromosomal abnormalities, such as aberrations of chromosomes 5, 7, or 8, FLT_3–internal tandem duplication (ITD), and fewer abnormalities that are associated with a more favorable outcome, such as t(8;21) or inv(16) (Table 96–6).[15]

Recent studies suggest that ethnicity may be an important predictor of outcome in children with AML. Investigators found that African Americans treated with chemotherapy had a significantly worse outcome than White people, perhaps suggesting race-related pharmacogenetic differences. Body mass index may also affect the prognosis of children with AML. Underweight patients and overweight patients were less likely to survive than normal-weight patients because of a greater risk of treatment-related deaths. Current clinical trials in adults and pediatrics strongly suggest that patients with detectable MRD at the end of induction therapy or consolidation are strongly associated with the risk of relapse.[14]

TREATMENT

Desired Outcome

The primary objective in treating patients with acute leukemia is to achieve a continuous complete remission (CCR). Remission is defined as the absence of all clinical evidence of leukemia with the restoration of normal hematopoiesis. For both ALL and AML,

Clinical Presentation and Diagnosis of ALL[9,10]

General

- Typically, patients have symptoms for 1–3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

Symptoms

- The patient may present with weakness, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Patients often present with bone pain secondary to expansion of the marrow cavity from leukemic infiltration.
- CNS involvement is common at diagnosis.

Signs

- Temperature may be elevated secondary to an infection associated with a low WBC count.
- Petechiae and bleeding are indicative of thrombocytopenia.
- Patients may present with organ involvement, such as peripheral adenopathy, hepatomegaly, and splenomegaly.
- T-lineage ALL may present with a mediastinal mass.

Laboratory Tests

- CBC with differential is performed.
- The anemia is usually normochromic and normocytic. Approximately 50% of children present with platelet counts of less than $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$). The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts over $100 \times 10^3/\text{mm}^3$ ($100 \times 10^9/\text{L}$), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- Electrolytes: Potassium and phosphorus often are elevated. Calcium usually is low.
- Coagulation disorders: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia.

Other Laboratory Tests

Flow cytometric evaluation of bone marrow and peripheral blood is performed to characterize the type of leukemia as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. Diagnosis is established by the presence of 20% or more lymphoblasts in the bone marrow or peripheral blood. Lumbar puncture with CSF examination is standard of care at the time of diagnosis to assess for CNS involvement.

Clinical Presentation and Diagnosis of AML[14,15]

General

- Patients may have symptoms of AML for 1 to 3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

Symptoms

- The patient may present with weakness, bone pain, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Chloromas (localized leukemic deposits named after their color) may be seen, especially in the periorbital regions and as skin infiltrates.
- Gum hypertrophy is indicative of AML M4 and AML M5 subtypes.
- Disseminated intravascular coagulation may be present in all AML subtypes but is common in AML M3 and is associated with generalized bleeding or hemorrhage.
- Lymphadenopathy, massive hepatosplenomegaly, and bone pain are not as common in AML as in ALL.

Signs

- Temperature may be elevated secondary to an infection associated with a low WBC count.
- Petechiae and bleeding are indicative of thrombocytopenia.

Laboratory Tests

- CBC with differential is performed.
- The anemia is usually normochromic and normocytic.
- Approximately 50% of children present with platelet counts of less than $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$).
- The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts of over $100 \times 10^3/\text{mm}^3$ ($100 \times 10^9/\text{L}$), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- Electrolytes: Potassium and phosphorus are often elevated. Calcium is usually low.
- Coagulation disorders: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia.

Other Diagnostic Tests

Flow cytometric evaluation of bone marrow and peripheral blood to characterize the type of leukemia as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. The presence of greater than 20% blasts in the bone marrow is diagnostic for AML. At diagnosis, an LP is performed for monocytic differentiation, mixed **phenotype** acute leukemia, WBC count > 40,000/mcL at diagnosis, or extramedullary disease.

Table 96–6

Risk Assessment of AML

Risk Category	Genetic Abnormality
Favorable	t(8;21)(q22;q22.1); *RUNX1-RUNX1T1* inv(16)(p13.1q22) or t(16;16)(p13.1;q22); *CBFB-MYH11* Biallelic mutated *CEBPA* Mutated *NPM1* without *FLT3ITD* or *FLT3-ITD*$^{\text{low}}$
Intermediate	Mutated *NPM1 and FLT3-ITD*$^{\text{high}}$ Wild-type *NPM1* without *FLT3-ITD* or with *FLT3-ITD*$^{\text{low}}$ (without adverse-risk genetic lesions) t(9;11)(p21.3;q23.3); *MLLT3-KMT2A* Cytogenetic abnormalities not classified as favorable or adverse
Poor	t(6;9)(p23;q34.1); *DEK-NUP214* t(v;11q23.3)*; KMT2A* rearranged t(9;22)(q34.1;q11.2); *BCR-ABL1* inv(3)(q21.3q26.2) or t(3;3)(q21.3;q26.2); *GATA2, MECOM(EVI1)* –5 or del (5q); –7; –17/abn(17p) Complex karyotype, monosomal karyotype Wild-type *NPM1* and *FLT3-ITD*$^{\text{high}}$ Mutated *RUNX1* Mutated *ASXL1* Mutated *TP53*

Adapted from National Comprehensive Cancer Network. Acute Myeloid Leukemia (Age >/= 18 years) (Verson 3.2020). Available from: http://www.nccn.org

remission induction is achieved with the use of myelosuppressive chemotherapy that initially induces a state of bone marrow aplasia as the leukemic cells die followed by a slow return and proliferation of normal cells. After this period, hematopoiesis is restored. Failure to achieve remission in the first 7 to 14 days of therapy is highly predictive of later disease recurrence. This again represents the growing importance of MRD in prognosis and treatment.

Nonpharmacologic Therapy

This year, roughly 1.8 million people will be diagnosed with cancer in the United States.[2] With improvements in detection and treatment, approximately two-thirds of those diagnosed with the disease can expect to be alive in 5 years. With improving longevity, the cumulative adverse effects of both the disease and treatment are becoming an increasingly important issue. "Late-effects" data show that both adult and pediatric cancer survivors are at greater risk for developing second malignancies, cardiovascular disease, diabetes, and osteoporosis than those in the general population. With respect to the growing population of pediatric cancer survivors, data confirm that they are eight times more likely than their siblings to have a severe or life-threatening chronic health condition. For example, the survivors of pediatric ALL have an increased risk of obesity, avascular necrosis, infertility, and associated comorbidities.[13] Thus, it is important to provide supportive care and counseling related to nutrition, smoking cessation, and exercise as a part of their active treatment. Healthcare professionals should think beyond the immediate treatment-related issues of their patients and provide appropriate, active assistance to promote healthy lifestyles and encourage patients to take active roles in pursuing general preventive health strategies.[13]

Pharmacologic Therapy: ALL

The treatment for ALL consists of five main elements: remission induction (the initial tumor reduction leading to morphologic remission), CNS-directed treatment, intensive postremission consolidation regimens, interim maintenance/delayed intensification followed by a prolonged maintenance phase. Different blocks of chemotherapy having differing intensity depend on the group of patients at risk with increasingly intensive regimens corresponding to more aggressive disease categories.[16] The total duration of treatment is 2–3 years.

▶ *Remission Induction*

KEY CONCEPT The initial treatment for acute leukemias is called remission **induction** lasting four to 6 weeks. The purpose of induction is to induce a remission, a state in which there are no identifiable leukemic cells in the bone marrow or peripheral blood with light microscopy.[16]

KEY CONCEPT Current induction therapy for ALL typically consists of vincristine, asparaginase, and a steroid (prednisone or dexamethasone). An anthracycline is added for higher risk patients. Although induction treatment produces 95% CR in children, it declines to no more than 60% in patients older than 60 years of age.

Patient Encounter 2, Part 1

A 34-year-old woman presents to urgent care with symptoms of rapid onset of fatigue and shortness of breath. On review of systems, she endorses new onset epistaxis. On physical exam, she is febrile with a temperature of 38.8°C, she appears pale, and she has petechiae on her palate.

The physician orders a CBC with differential which reveals a normochromic, normocytic anemia with a hemoglobin of 6 g/dL (60 g/L, 3.6 mmol/L; normal 11.7–15.7 g/dL, 117–150 g/L, 7.3–9.7 mmol/L), hematocrit of 18% (0.18; normal 35%–47%, or 0.35–0.47), and white blood cell (WBC) count of $2.6 \times 10^3/\mu L$ ($2.6 \times 10^9/\mu L$). The differential on the WBC count reveals 75% (0.75) lymphocytes (normal 20%–40%, or 0.2–0.4), 20% (0.2) neutrophils (normal 55%–62%, or 0.55–0.62), and 5% (0.05) myeloblasts (normal 0%). Based on this information, a bone marrow aspirate and biopsy are performed, which reveal 85% (0.85) myeloblasts. Cytogenetic studies are normal and molecular studies reveal an NPM1 mutation without FLT3-ITD.

What chemotherapy drugs should this patient receive as part of his AML induction?

a. Dexamethasone, vincristine, and pegaspargase

b. Daunorubicin, cytarabine, and gemtuzumab ozogamicin

c. Daunorubicin, vincristine, pegaspargase

d. Dexamethasone, vincristine, pegaspargase, daunorubicin

What is the role of postremission chemotherapy?

Patient Encounter 2, Part 2

This patient had a bone marrow aspiration performed on day 14 and again at the time of blood count recovery. Both showed that the patient was in a complete morphologic remission.

What is the role of allogeneic stem cell transplant?

Adults, unlike children, are universally considered to be at high risk for relapse; therefore, their induction regimens include an anthracycline (daunorubicin or doxorubicin) in addition to the standard steroid and vincristine treatment that have been the backbone of treatment for this disease for the last 50 years. Dexamethasone often replaces prednisone because of its longer half-life and better CNS penetration.[17] Although dexamethasone possesses more favorable pharmacologic characteristics than prednisone, its use may be associated with more aseptic osteonecrosis of the femoral and humeral heads as well as an increase in life-threatening infections.[16] Several different agents for asparagine depletion exist, including pegylated (PEG) asparaginase and Erwinia asparaginase. Pegylated asparaginase has been altered by covalently attaching a polyethylene glycol that has shown to result in an extended half-life and reduced immunogenicity. Erwinia is usually given to those patients who have had an allergic reaction to pegylated asparaginase and requires a more frequent administration schedule.[16]

▶ CNS Prophylaxis

KEY CONCEPT Leukemic invasion of the CNS is an almost universal event in patients even in those whose cerebrospinal fluid (CSF) cytology shows no apparent disease. Thus, all patients with ALL and AML leukemia receive intrathecal (IT) chemotherapy. Although this is often referred to as "prophylaxis," it more realistically represents treatment. CNS prophylaxis relies on IT chemotherapy (eg, methotrexate, cytarabine, and corticosteroids), systemic chemotherapy with dexamethasone and high-dose methotrexate, and craniospinal irradiation (XRT) in selected high-risk patients.[18] Cranial radiation use diminished substantially after the efficacy of IT treatment was evident, and the toxicities associated with radiation; learning disabilities, growth retardation, and secondary malignancies were recognized. IT therapy has replaced cranial XRT as CNS prophylaxis for all except the very high-risk patients and those with T-cell ALL who are at higher risk of CNS disease. Many protocols reserve radiation for those at higher risk of CNS relapse while some institutions defer its use altogether.[16]

Inexplicably, the treatment of CNS leukemia has not impacted the OS of adults as it has for childhood ALL. With IT chemotherapy alone, the incidence of CNS relapse in adults is 9% to 13% compared with less than 3% in children.[18]

▶ Postremission Consolidation Regimens

Consolidation After completion of induction and restoration of normal hematopoiesis, patients begin consolidation. The goal of consolidation is to administer dose-intensive chemotherapy to reduce the burden of residual leukemic cells. It is in this and subsequent treatment phases that the remaining leukemic burden is eliminated.[17] Several regimens use agents and schedules designed to minimize the development of drug cross-resistance. Consolidation is an effective strategy to prevent relapse in children with ALL, but its benefits in adults are less clear.

In children, the intensity of the consolidation treatment is determined by the child's risk classification and the degree of cytoreduction during induction (MRD). Patients who respond slowly to induction therapy (as determined by bone marrow examination early in induction) are at higher risk of relapse and treated with more aggressive regimens.[16]

Reinduction (Delayed Intensification and Interim Maintenance) The typical duration of interim maintenance is approximately 8 weeks. Treatment usually consists of low-intensity therapy added to continue remission and lower cumulative toxicity. The Berlin–Frankfurt–Munster (BFM) study group introduced a treatment element called delayed intensification (or reinduction) therapy. This therapy consisted of repetition of the initial remission induction therapy administered approximately 3 months after remission. This regimen, similar to consolidation, has been adopted as a component of treatment for children by virtually all institutions.[5]

Intensification regimens vary in their aggressiveness and drug regimens depending on the patient's risk group and immunophenotype. For example, the use of escalating doses of methotrexate intravenously (Capizzi methotrexate regimen) without leucovorin plus pegasparaginase was reportedly to be superior to high-dose methotrexate in 90% of patients receiving cranial radiation therapy.[19]

▶ Maintenance

The purpose of maintenance therapy is to further eliminate leukemic cells and produce an enduring CCR. The two most important agents in maintenance chemotherapy are a combination of oral methotrexate and 6-mercaptopurine. Improved outcome is associated with increasing 6-mercaptopurine doses to the limits of individual tolerance based on absolute neutrophil count (ANC). The benefit of adding intermittent "pulses" of vincristine and a steroid (usually dexamethasone) to the antimetabolite backbone remains unclear, but it is common practice in most modern treatment regimens.[5] The goal is to induce a moderate immunosuppression and leukemic cell kill.

6-Mercaptopurine is a key agent in maintenance therapy. It has a complex metabolism and is initially metabolized by thiopurine methyltransferase (TPMT).[1] TPMT activity is variable with about 90% of patients having normal activity, about 10% having intermediate activity, and fewer than 1% having very low or no activity. Genetic polymorphisms in *TPMT* are inherited in an autosomal recessive fashion and have a profound influence on 6-mercaptopurine tolerance.[16]

TPMT screening is recommended for children starting therapy with 6-mercaptopurine. Children who possess alleles that have diminished activity require 6-mercaptopurine dose reductions of 50% to 90% to prevent severe immunosuppression and infection. Many studies include guidelines to for dose modification in achieving the goal of balancing the risk of inadequate myelosuppression with the risk of severe neutropenia.[16] Despite these reductions, these children have equivalent OS when compared with those receiving full-dose 6-mercaptopurine. The optimal duration of maintenance therapy in both children and adults is unknown, but most regimens are given for 2 to 3 years; extension of the regimen beyond 3 years has not shown any additional benefit.

ALL in Infants and Young Children

Infants and children younger than 1 year of age account for approximately 5% of all children with ALL and have the worst outcome of any group with this disease. These patients have several poor prognostic features at diagnosis, including hyperleukocytosis, hepatomegaly, splenomegaly, and CNS leukemia.[11]

A characteristic finding in up to 80% in this group is a chromosomal translocation involving the *MLL* gene located at 11q23. There are multiple possible rearrangements of this gene with other chromosomes, and all confer a poor prognosis. In vitro, blasts of these patients showed greater drug resistance to prednisolone and L-asparaginase than those from other patients, although they are more sensitive to cytarabine.[12] Based on this information, several studies are testing the efficacy of intensified chemotherapy that includes high-dose cytarabine. Another achievement is the prevention of CNS relapse using IT cytarabine in conjunction with high-dose systemic cytarabine. This combination has eliminated the need for cranial XRT in this young population. Even with major advances in cure rates for the general pediatric ALL population, in whom survival is 80% or more, the long-term survival of infants is only about 50%.[1]

ALL in Adolescents and Young Adults

As noted previously, age is an important prognostic factor in ALL. Adolescents and adult patients have generally been shown to have poorer survival than children.[13] However, the group of patients between late adolescence and age 39 years (adolescents and young adults) have a substantially better outcome than older adult patients, but worse outcomes when compared to pediatric counterpart. When treated with pediatric protocols the disease-free survival (DFS) is 70%, compared historically to 30% to 45%.[13] The pediatric regimens used to treat this group of patients contain the BFM backbone: steroids, vincristine, asparaginase, and CNS prophylaxis.[20] The reasons for improved survival in this age-group are not entirely clear, and multiple factors are likely to play a role. Among the likely explanations is that pediatric protocols use more aggressive and prolonged postremission consolidation therapy before maintenance. Other proposed explanations are the potential differences in disease biology in this versus older age patients, more intense CNS prophylaxis, and the greater degree of social support and better compliance fostered in a pediatric environment. Current and planned trials are focusing on the potential of extending this treatment approach to patients age 40 years and possibly older.

Patient Encounter 3

Your patient is a 52-year-old woman who presented to the emergency department after a few days of petechiae on her left flank and inner thigh, diffuse myalgias, and intermittent fevers of 101°F. She was found to have hyperleukocytosis (white blood cell [WBC] count 150,000/L) with 75% blasts in peripheral blood and thrombocytopenia (platelet count 8,000/L). Cytogenetic analysis demonstrated a t(15;17) mutation.

Which of the following is the most appropriate remission induction therapy for EB based on this information?

a. Blinatumomab

b. Tretinoin (ATRA) plus arsenic trioxide

c. High-dose cytarabine

d. 7 + 3 with cytarabine and daunorubicin

On the third day of treatment, your patient begins to complain of fever, respiratory distress, and fluid retention. Chest imaging reveals pulmonary opacities and presence of a pleural effusion.

What is the most likely cause of this process?

a. Pneumonia

b. Acute respiratory distress syndrome

c. Differentiation syndrome associated with ATRA

d. Myocardial infarction

What is the primary treatment associated with the above condition?

a. Robitussin

b. Dexamethasone

c. Furosemide

d. Aspirin

ALL in Adults

The incidence of ALL in adults ages 30 to 60 years is only 2 per 100,000 persons per year compared with almost 10 per 100,000 in children. The conventional risk factors such as high WBC counts, older age, and CNS disease hold true in adults as in children. However, the significance of cytogenetic and molecular markers that are so important in children seems to be less predictive of outcome in adults. An exception is the adverse prognostic factor, the presence of the *BCR-ABL* translocation (Ph^+) just as in childhood ALL. This occurs in 25% of adults and in up to 50% of elderly patients.[21] The use of second-generation tyrosine kinase inhibitors, potent inhibitors of the Ph^+-associated BCR-ABL tyrosine kinase, has now become a standard of practice for all patient groups with Ph^+ disease.[22-24] Results show that the combination of these agents with conventional chemotherapy improves remission rates as well as OS compared with the use of conventional chemotherapy alone.[22-24]

Currently, induction and consolidation regimens in adults are similar to pediatric regimens. Aggressive postinduction regimens are not as well tolerated in this population, particularly in patients older than 60 years, and are associated with a much higher incidence of toxicity and treatment-related deaths.[7] Some investigators are studying "moderate-dose" consolidation regimens that are better tolerated, although long-term efficacy data are lacking. Even though remissions are achieved in 80% to 90% of adult patients, 5-year DFSs are only in the 30% to 40% range. Among elderly patients, the outcome is even poorer with no more than 20% having long-term survival.

Relapsed ALL

Relapse is the recurrence of leukemic cells at any site after remission has been achieved. Leukemic blasts recurring after remission are much more drug resistant than the blasts at initial diagnosis. **KEY CONCEPT** Bone marrow relapse is the major form of treatment failure in 15% to 20% of patients with ALL. Most relapses have the same immunophenotype and cytogenetic changes seen in the original disease. Extramedullary sites of relapse include the CNS and the testicles. Extramedullary relapse, although once common, has decreased to 5% or less because of effective prophylaxis. Site of relapse and the length of the first remission are important predictors of second remission and OS. Marrow relapses occurring less than 18 to 24 months into first remission are associated with a poor survival, but longer periods of remission (more than 36 months) have a much higher chance of survival.[25] Treatment strategies for relapsed ALL include chemotherapy or allogeneic hematopoietic stem-cell transplant (allo-HSCT). Even though patients undergoing allo-HSCT are less likely to relapse, treatment-related toxicity leads to a high incidence of morbidity and mortality. Clofarabine, a next-generation deoxyadenosine analogue, has shown considerable activity in children and adults with refractory acute leukemias.[26,27] Blinatumomab, a MAB that targets CD19, is approved for Ph-negative relapsed or refractory ALL in adults and pediatric patients.[28] Inotuzumab ozogamicin is an antibody–drug conjugate composed of a humanized anti-CD22 MAB that is conjugated to the cytotoxic agent calicheamicin. It binds with high affinity to CD22 that is expressed in the majority of B-cell blasts in patients with B-cell ALL and is approved in B-cell precursor relapsed or refractory ALL.[29] Nelarabine is an antineoplastic agent that appears to bind preferentially to T cells and does show a significant response rate in patients with relapsed or refractory T-lineage ALL.[30] Tisagenlecleucel is an anti-CD19 chimeric antigen receptor (CAR) T-cell therapy that has been shown to induce durable remissions in patients with relapsed and refractory B-cell ALL.[31] A significant toxicity of this treatment is cytokine release syndrome, and it is only offered at select centers with training in managing this toxicity.[31]

Treatment of AML

As with ALL, the primary aim in treating patients with AML is to induce remission and thereafter prevent relapse. Treatment of AML is divided into two phases: induction and consolidation. The prognosis of patients with AML varies dramatically and is dependent on age and performance status as well as risk stratification established by cytogenetic and molecular changes established at the time of diagnosis.[14] Those in good risk categories may have 3-year overall survival rate as high as 66% while those with high-risk features have a significantly higher risk of treatment failure.[14]

KEY CONCEPT The current induction therapy for AML usually consists of a combination of cytarabine and daunorubicin. The second phase of treatment for AML is called consolidation. The purpose of this phase is to further enhance remission with more cytoreduction.[14]

▶ *Remission Induction*

The goal of induction chemotherapy in AML is essentially identical to that in ALL—"empty" the bone marrow of all hematopoietic precursors and allow repopulation with normal cells. The combination of an anthracycline (eg, daunorubicin, doxorubicin, or idarubicin) and the antimetabolite cytarabine forms the backbone of AML induction therapy. The most common induction regimen (7 + 3) combines daunorubicin for 3 days with cytarabine on days 1 to 7.[14] The remission rate for this combination is approximately 60% to 80% adults with AML.[14] Adding gemtuzumab ozogamicin, an anti-33 MAB, to induction therapy for patients with favorable cytogenetics improves overall survival.[32] Midostaurin, an oral multitarget kinase inhibitor, is approved by the FDA for treatment of FLT3-positive AML. It is added on days 8 to 21 of the convention 7 + 3 induction chemotherapy and also on days 8 to 21 of high-dose cytarabine consolidation.[33] Liposomal daunorubicin and cytarabine is a treatment option for those with therapy-related AML, antecedent myelodysplastic syndrome, or de novo AML with myeloysplastic-related cytogenetic abnormalities.[34]

▶ *Postremission Chemotherapy*

In AML, postremission chemotherapy is often referred to as consolidation therapy. Several cycles of intensive postremission chemotherapy combining non–cross-resistant agents given every 4 to 6 weeks substantially improve DFS. Without postremission treatment, all patients would relapse within several weeks. This is analogous to the consolidation and other phases of postremission chemotherapy in ALL. The use of high-dose cytarabine in postremission therapy is a standard option with doses ranging from 1.5 to 3 g/m^2 for two to four cycles.[14]

Allogeneic Hematopoietic Stem Cell Transplantation Hematopoietic stem-cell transplantation (HSCT) is the most effective treatment for AML. Its promising benefit must be weighed against the potential risk of transplantation-related sequelae. HSCT in first remission is generally reserved for those with higher risk disease and shows no benefit in patients with good risk disease profile.[14]

The availability of human leukocyte antigen (HLA)-matched sibling donors determines whether patients undergo HSCT as postremission treatment. To facilitate this process, it is important to obtain HLA typing on all younger patients and siblings shortly after diagnosis. Patients who do not have an HLA-matched sibling proceed to postremission therapy with chemotherapy alone.

Complications and benefits of allogeneic HSCT are described in Chapter 98. Transplant-related mortality following matched-sibling allo-HSCT is 20% to 30% in most series. Complications from transplantation increase with age; therefore, patients older than 60 years of age rarely receive a myeloablative allo-HSCT. Because the average age of AML patients is 65 years, most patients with this disease are not candidates for this form of therapy. For older patients up to 70 years of age, a reduced-intensity (mini- or nonmyeloablative allogeneic) transplant may be an option. These transplants use less intensive preparative regimens and rely on the allogeneic graft-versus-leukemia (GVL) effect to eliminate their disease.[35]

The role of HSCT, particularly whether it should be performed during the first CR or reserved for second remission, remains a controversial issue in AML. HSCT is often reserved for patients who are considered high risk.[14] Some AML patients may be curable with conventional-dose chemotherapy alone.

Autologous Hematopoietic Stem Cell Transplantation Because many AML patients lack an HLA-identical donor, investigators began to consider the use of the patient's own bone marrow, obtained while in CR, as a source of hematopoietic regeneration. However, relapse continues to be a problem secondary to the presence of residual disease in the graft. Despite the reduced morbidity and mortality associated with auto-HSCT, this type of transplant does not compare favorably to standard postremission chemotherapy.[35]

▶ *CNS Therapy*

The prevalence of CNS disease at diagnosis of AML is approximately 15%. Features associated with the risk of CNS leukemia include hyperleukocytosis, monocytic, or myelomonocytic leukemia (FAB M4 or M5), and young age.[15] Adequate CNS prophylaxis is an essential component of therapy. Patients with CNS disease at diagnosis can be cured with IT therapy alone without the use of cranial XRT. In most cases, IT cytarabine with or without methotrexate and systemic high-dose cytarabine provide effective treatment.

AML in Infants

AML in infants younger than 12 months of age shows clinical and biological characteristics different from those of older children. The disease phenotype is more commonly monoblastic or myelomonoblastic (M4, M5), and the patients usually present with hyperleukocytosis. Extramedullary involvement is common, often involving skin and other organs. As in infant ALL, there is a high incidence of translocations involving the *MLL* gene in infant

AML. The number of infant AML trials reported is limited, but the EFS of this population is similar to that of older children with AML. This is in marked contrast to the outcomes for infants with ALL for whom the EFS is much lower than in older children.[36]

AML in the Elderly

AML is the most common acute leukemia in the elderly. Compared with younger patients with the same disease, older adults have a poor prognosis and represent a distinct population with regard to the biology of their disease. Older adults have a lower incidence of favorable chromosomal aberrations and a higher incidence of unfavorable aberrations.[14] Fms-like tyrosine kinase 3 (*FLT3*) that is an AML oncogene plays an important role in AML pathogenesis and was associated with a poor outcome. *FLT3*-ITD is common in adults but is only found in 12% of the pediatric population.[37] Older patients also have more comorbidities, such as type 2 diabetes, obesity, and other physiologic limitations. Thus, the poor prognosis of AML in this population is only partly the result of unfavorable biology.

In older adults, in contrast to children, AML is more likely to arise from a proximal bone marrow–stem cell disorder, such as MDS, or present as a secondary, prior treatment-related leukemia. These forms of AML are notoriously poorly responsive to conventional chemotherapy and, thus, have a lower CR rate and poorer survival.[25]

As previously noted, age is an important prognostic factor. Older adults are not as tolerant of or as responsive to remission induction and consolidation chemotherapy as younger patients. Furthermore, even in good-risk disease, long-term survival for patients older than 60 years is only 33% compared with 66% for younger adults.[14] Liposomal daunorubicin and cytarabine is a treatment option for older patients who have secondary AML.[34] BCL-2 inhibitor, venetoclax, has also shown efficacy and tolerability in combination with either of two hypomethylating agents, decitabine, or azacitidine.[38]

Relapsed AML

Even though 75% to 85% of patients with AML achieve a remission, only about 50% survive. Patients who relapse usually respond poorly to additional treatment and have a shorter duration of remission. This is probably related to drug resistance induced during induction and certain chromosomal abnormalities.

Even though there is no standard therapy for relapse, most studies have shown that high-dose cytarabine-containing regimens have considerable activity in obtaining a second remission. Cytarabine has been used in combination with mitoxantrone, etoposide, fludarabine, 2-chlorodeoxyadenosine, and clofarabine.[39,40] For patients unable to tolerate intensive chemotherapy, low-dose cytarabine and the hypomethylating agent, azacitidine, are also options for relapsed disease.[41] Venetoclax in combination with either decitabine or azacitidine is also an alternative in the relapsed setting.[42] There are also targeted agents that can be used in the relapsed setting if patients harbor the appropriate mutations. Gilteritinib is an FLT3 inhibitor approved for AML patients with an *FLT3-ITD* mutation in relapsed setting.[43] Enasidenib is an oral inhibitor of mutant *IDH2* proteins and is approved for use in patients with relapsed AML who harbor *IDH2* mutations.[44] Similarly, ivosidenib is an *IDH1* inhibitor that is approved for use in relapsed AML patients with an *IDH1* mutation.[45]

After a patient has achieved a second remission with conventional chemotherapy, allo-HSCT is the therapy of choice. For patients without an HLA-matched sibling, a matched unrelated donor (MUD) or cord blood transplant may be a reasonable alternative. The combination of myeloablative high-dose chemotherapy and the GVL effect is thought to offer the best chance of survival in AML.

Complications of Treatment

▶ *Tumor Lysis Syndrome*

Tumor lysis syndrome (TLS) is an oncologic emergency that is characterized by metabolic abnormalities resulting from the death of blast cells and the release of large amounts of purines, pyrimidines, and intracellular potassium and phosphorus. Uric acid, the ultimate breakdown product of purines, is poorly soluble in plasma and urine. Deposition of uric acid and calcium phosphate crystals in the renal tubules can lead to acute renal failure. Many patients with acute leukemia, especially those with a high tumor burden, are at risk for TLS during the first several days of chemotherapy. Measures to prevent TLS include aggressive hydration to increase urine output, and allopurinol to reduce uric acid production. However, on some occasions, the use of rasburicase is indicated. Rasburicase is a urate oxidase that catalyzes the oxidation of uric acid to allantoin, which is much more soluble than uric acid and excreted more easily. Rasburicase reduces the hyperuricemia that subsequently reduces the risk of acute renal failure and other clinical manifestations.[46] Given its high cost, rasburicase generally is restricted to patients with high WBC counts ($> 50 \times 10^3/\text{mm}^3$, $50 \times 10^9/\text{L}$) and uric acid levels greater than 8 mg/dL (476 μmol/L).

▶ *Infection*

Infection is a primary cause of death in acute leukemia patients. Both the disease and aggressive chemotherapy cause severe myelosuppression, placing the patient at risk for sepsis.

The therapy for AML is extremely myelosuppressive. Adults with AML have a 10% to 20% induction mortality rate secondary to infection and bleeding complications. Therefore, patients receiving induction therapy usually are hospitalized for the first 4 to 6 weeks of therapy.

It is important to recognize that symptoms and signs of infection may be absent in a severely immunosuppressed or neutropenic patient. Fever (higher than 38.3°C [100.9°F]) in a neutropenic patient is a medical emergency. Because the progression of infection in neutropenic patients can be rapid, empirical antibiotic therapy is started whenever a fever is documented. A commonly used initial antibiotic agent is cefepime, a fourth-generation cephalosporin that has good antipseudomonal coverage as well as adequate coverage against *Streptococcus viridans* and pneumococci.

Disseminated fungal infections most commonly caused by *Candida* and *Aspergillus* species can be life-threatening in patients with AML. Antifungal prophylaxis is standard in neutropenic AML patients and posaconazole is generally recommended.[47] Fluconazole and itraconazole are not considered ideal, because they are not effective against *Aspergillus* species and other molds.

Antibiotic prophylaxis with a fluoroquinolone antibiotic is recommended in AML patients during times of neutropenia.[47]

Antiviral prophylaxis with acyclovir, famciclovir, or valacyclovir is recommended in AML patients during times of neutropenia.[47]

▶ *Secondary Malignancies*

Secondary malignancies are a risk of the successful treatment of a prior cancer or the use of cytotoxic agents in a variety of autoimmune diseases. The chemotherapy agents used, especially alkylating agents and topoisomerase II inhibitors, predispose patients to secondary hematopoietic neoplasms. As the aggressiveness of treatment and the number of survivors of AML increase, the risk of secondary neoplasms also may rise. There are two different types of second malignancies: acute leukemia, which is generally myeloid in origin, or MDS. There are also reports of secondary solid tumors, especially within regions of prior radiation exposure. The latency period between the end of treatment and the development of a secondary leukemia is generally in the range of 5 to 10 years. For those patients who develop secondary solid malignancies, the latency may be as long as 10 to 20 years.

The incidence of second cancers attributed to alkylators peaks 4 to 6 years after exposure and plateaus after 10 to 15 years. Higher cumulative doses and older age at the time of treatment are risk factors for this type of cancer.

Epipodophyllotoxins (etoposide and others) can induce a second malignancy characterized by balanced chromosomal translocations and short latency periods (2–4 years). The risk of this leukemia is related to schedule (dose intensity) and the concomitant use of other agents (L-asparaginase, alkylating agents, and possibly antimetabolites). The prognosis for topoisomerase II inhibitor–related secondary leukemia is extremely poor. Only about 10% of these patients survive after salvage chemotherapy, and only 20% survive after HSCT.

Ionizing radiation therapy is also a cause of secondary malignancies. These secondary tumors generally develop within or adjacent to the previous radiation field. These cancers often have a prolonged latency, typically 15 or more years, but shorter latencies (5–14 years) are known. Higher doses of radiation and younger age are associated with an increased risk of secondary malignancy.[1]

Unlike children, adults may have other factors that predispose them to secondary malignancies. Lifestyle choices such as tobacco use, alcohol use, and diet are implicated in influencing the development of secondary neoplasms in the adult population.

Now that 80% or more of children survive their primary cancers, the incidence of secondary neoplasms may increase. Recognizing this potential, many treatment regimens for children are being modified appropriately to reduce exposure to alkylators, topoisomerase inhibitors, and radiation.[1] Children in long-term follow-up are screened for secondary malignancies and other disease and treatment-related disabilities that accompany childhood cancer. Similar screening and educational opportunities are not as established in adult survivors.

▶ *Late Effects*

With increased success in pediatric clinical trials, the OS rate for pediatric cancers has increased markedly over the last 40 years. For acute lymphoblastic leukemia, the OS rate is now about 90% in pediatrics.[5] **KEY CONCEPT** Despite this significant increase in survival, many patients, particularly pediatric cancer survivors, have disease- or treatment-related disabilities. As many as 50% to 60% of these survivors are estimated to have at least one chronic or late-occurring complication of treatment.[1] In leukemia, the intensified use of methotrexate may be responsible for some sporadic neurotoxicity seen in children and adults. Likewise, the use of pharmacologic doses of glucocorticoids has been associated with avascular necrosis of bone in older children and adults. Adjustments to glucocorticoid administration schedules can reduce the risk.[5] High cumulative doses of anthracyclines can cause irreversible cardiomyopathy. Cranial XRT is now less frequently used for CNS leukemia prophylaxis but can cause neuropsychological and neuroendocrine abnormalities that may lead to obesity, short stature, or precocious puberty.[1] As newer and more intensive treatments enter clinical trials, continued long-term follow-up of childhood ALL survivors is imperative to define the risks and develop strategies to decrease toxicity.[5]

Supportive Care

Because of the need for repeated venous access, a central venous catheter or infusion port is placed before starting treatment. These devices are useful not only for delivery of chemotherapy but also to support patients during periods of myelosuppression. Infection and bleeding complications are the primary causes of mortality in patients with leukemia.

Platelet transfusions are a common tool to prevent hemorrhage. Patients with uncomplicated thrombocytopenia can be transfused when the platelet count falls below $10 \times 10^3/\text{mm}^3$ ($10 \times 10^9/\text{L}$). Patients who are either highly febrile or actively bleeding may require transfusions at higher levels. Red blood cell transfusions generally are not necessary for a hemoglobin concentration greater than 8 g/dL (80 g/L, 4.97 mmol/L).

There is much controversy regarding the routine use of colony-stimulating factors (CSFs) (eg, granulocyte colony-stimulating factor [G-CSF] and granulocyte-macrophage colony-stimulating factor [GM-CSF]) in neutropenic patients. Even though several clinical trials have shown the time to ANC recovery is decreased with a CSF, none have demonstrated that CSFs statistically influence infection-related mortality. At present, the use of CSFs (G-CSF most commonly) generally is limited to those chemotherapy regimens that place the patient at highest risk for prolonged neutropenia.

OUTCOME EVALUATION

Developing strategies for the treatment and monitoring of acute leukemias begin with risk stratification. Understanding the likely risk of relapse determines the aggressiveness and length of therapy. Remission status and MRD after the induction phase of treatment must be closely observed. Failure to obtain morphologic bone marrow remission by day 28 is a very adverse prognostic sign and dictates further induction treatment. For those who have a morphologic remission, quantification of MRD has become an increasingly important prognostic factor. Levels of residual less than 0.01% appear to be associated with better outcomes.

A clinician is generally charged with developing a plan to educate patients and families about their drugs and doses. This is a critical responsibility; it is imperative that the patients and their families understand why they are receiving their medications and how to take them. Frank, open discussion (with the family or patient in possession of their prescriptions) goes a long way toward preventing errors that occur as a result of "assuming" that they understand their medications. If modifications are necessary secondary to toxicity or inadequate response, establish a plan for treatment change. Remember that individual patients often do not fit the "average" patient profile, and dose modifications are frequently needed. The practitioner should be familiar with dosing ranges, WBC count, and other parameters that indicate appropriate treatment response. Based on response to prior phases of treatment, the clinician should recognize potential toxicities in subsequent phases of treatment with the same or different drugs at similar or different doses.

Patient Care Process

Collect Information:

- Using the medical record collect the pertinent information on the presenting symptoms that made the patient seek out a healthcare provider.
- Perform a medication history, including over-the-counter and herbal medications.
- Confirmation of diagnosis including molecular and cytogenetic information from a bone marrow.
- Laboratory information, including CBC with differential, chemistry panel, disseminated intravascular coagulation (DIC) panel (D-dimer, fibrinogen, PT, and PTT), hepatitis, cytomegalovirus (CMV), and human immunodeficiency virus (HIV) status.
- Speak with patient, or patient's family in the instance of a pediatric patient, and assess patient or family's socioeconomic situation to evaluate ability to obtain prescription medications and/or resources for transplantation if necessary.

Assess the Information:

- Review patient's medication history prior to admission evaluating for indications and drug interactions including interactions with antifungals and oral chemotherapy.
- Review the patient's medical history looking for any medical condition that might predispose the patient to adverse effects from chemotherapy and supportive care medications, for example, look for a history of prolonged QT interval or heart failure.
- Speak to the patient about any risk factors that may predispose him to adverse effects.
- Ascertain the patient's understanding of the process for the treatment of acute leukemias and the need for compliance in prophylactic medications.

Develop a Care Plan:

- If patient has baseline hepatic, renal, cardiac issues, anticipate the need for dose modifications or changes in therapy.
- If there is a barrier to acquiring medications, develop a plan early in the patient's treatment to ensure that the patient can get the medications needed when discharged.
- Review and discuss the importance of being compliant with prophylactic medications with the patient or patient's family.
- Educate patient and patient's families about adverse effects of treatment for leukemia, and when it is necessary to call the cancer clinic or go to the emergency room.

Implement the Care Plan:

- When the patient is discharged from the hospital and seen at a clinic appointment, perform a medication history and reeducate about the importance of the medications and compliance.
- Evaluate new laboratory data to make sure all medications are dosed appropriately.
- Review medication list for drug interactions.
- Review side effect management with patient and patient's family, reeducating on need for home medications to treat side effects.
- Suggest nonpharmacological ways to minimize adverse effects.
- If patient is not tolerating or unable to manage adverse effects at home, work with providers to implement a new plan.

Follow-up: Monitor and Evaluate:

- At each clinic visit review medication list with patient.
- Check for drug interactions with all new medications.
- Review labs for changes in hepatic and renal function. Adjust dose or eliminate medication based on these results.
- Review effectiveness of symptom management plan with patient and patient's family.
- Reeducate as needed.

Abbreviations Introduced in This Chapter

ALL	Acute lymphocytic/lymphoblastic leukemia
allo-HSCT	Allogeneic hematopoietic stem cell transplant
AML	Acute myelogenous leukemia
ANC	Absolute neutrophil count
ANLL	Acute nonlymphocytic leukemia
BFM	Berlin–Frankfurt–Munster
CCR	Continuous complete remission
CD	Cluster determinant
CR	Complete remission
CSF	Cerebrospinal fluid
CSF	Colony-stimulating factor
CMV	Cytomegalovirus
DFS	Disease-free survival
DIC	Disseminated intravascular coagulation
EFS	Event-free survival
FISH	Fluorescent in situ hybridization
G-CSF	Granulocyte colony-stimulating factor
GM-CSF	Granulocyte-macrophage colony-stimulating factor
GVL	Graft-versus-leukemia
HIV	Human immunodeficiency virus
HLA	Human leukocyte antigen
HSCT	Hematopoietic stem cell transplantation
ITD	Internal tandem duplication
MAB	Monoclonal antibody
MDS	Myelodysplastic syndrome
MRD	Minimal residual disease
MUD	Matched unrelated donor
OS	Overall survival
Ph^+	Philadelphia chromosome
TLS	Tumor lysis syndrome
XRT	Irradiation

Chronic Leukemias and Multiple Myeloma

Amy M. Pick and Jared E. Matya

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the role of the Philadelphia chromosome in the pathophysiology of chronic myelogenous leukemia (CML).
2. Identify the clinical signs and symptoms and laboratory findings associated with CML, chronic lymphocytic leukemia (CLL), and multiple myeloma (MM).
3. Discuss first- and second-line treatment options for CML, including options for those patients with drug-resistant disease.
4. Describe the clinical course of CLL and distinguish which patients may be observed and who require treatment.
5. Compare the treatment options available for CLL, noting treatment differences based on the drug's toxicity profile.
6. Describe the clinical presentation and symptoms of MM.
7. Recommend the appropriate treatment for patients with MM, recognizing the importance of combination therapy and the role of autologous hematopoietic stem-cell transplant.

INTRODUCTION

Several diseases comprise chronic leukemia. The two most common forms are chronic myelogenous leukemia (CML) and chronic lymphocytic leukemia (CLL). The slower progression of the disease contrasts it from acute leukemia, with the survival of chronic leukemia often lasting several years without treatment. There have been numerous treatment advancements in the area of targeted therapy for each of these cancers, resulting in an increase in survival.

CHRONIC MYELOGENOUS LEUKEMIA

CML is a hematologic cancer that results from an abnormal proliferation of an early myeloid progenitor cell. The clinical course of CML has three phases: chronic phase (CP-CML), accelerated phase (AP-CML), and blast phase/crisis (BP-CML), with 90% of patients diagnosed in chronic phase.[1] Criteria for these phases is largely based on the percent blasts in the peripheral blood or bone marrow. Blast crisis resembles acute leukemia, and immediate aggressive treatment is required.

EPIDEMIOLOGY AND ETIOLOGY

There were an estimated 9110 new cases of CML diagnosed in 2021, accounting for 14% of all adult leukemias.[2] The incidence of CML increases with age, with the median age of diagnosis being 65 years.[3] Prior to the advent of imatinib, the annual mortality was 10% to 20%. Today, with the use of tyrosine kinase inhibitors (TKIs), the annual mortality has decreased to 1% to 2%.[1] In most newly diagnosed cases, the etiology cannot be determined. High doses of ionizing radiation and exposure to solvents such as benzene are recognized as risk factors.

PATHOPHYSIOLOGY

Cell of Origin

CML arises from a defect in an early progenitor cell. The pluripotent (noncommitted) stem cell is implicated as the origin of the disease; therefore, multiple cell lineages of hematopoiesis may be affected, including myeloid, erythroid, megakaryoid, and (rarely) lymphoid lineages. These cells remain functional in CP-CML, which is why patients in chronic phase are at low risk for developing infections.

Ph Chromosome

KEY CONCEPT The Philadelphia chromosome (Ph) results from a translocation between chromosomes 9 and 22, leaving a shortened chromosome 22. The Ph results in the formation of an abnormal fusion gene between the breakpoint cluster region and the Abelson proto-oncogene (*BCR-ABL1*), which encodes an overly active tyrosine kinase. The loss of tyrosine kinase activity control causes abnormal cellular proliferation and inhibition of apoptosis.[1] The molecular tools, quantitative reverse transcriptase-polymerase chain reaction and fluorescence in situ hybridization are used in the detection and monitoring of *BCR-ABL1* transcripts found in CML.[4]

Clinical Presentation and Diagnosis of CML[5]

Signs and Symptoms

- ~50% are asymptomatic at diagnosis
- Symptoms may include fatigue, fever, weight loss, and bleeding
- Organomegaly consisting of splenomegaly and hepatomegaly

Diagnostic Procedures

- Peripheral blood
- Bone marrow biopsy (percentage of blasts)
- Cytogenetic studies (presence of Ph and additional chromosomal abnormalities)
- Molecular testing (qPCR to detect *BCR-ABL1* transcripts as reported by International Scale (IS))

Laboratory Findings

- Peripheral blood
  - Leukocytosis (most present with WBC count > 100 × 10^9/L [100 × 10^3/mm^3])
  - Thrombocytosis (˜50% of patients in chronic phase)
  - Anemia
  - Basophilia
  - Presence of blasts
  - Elevated uric acid
- Bone marrow
  - Hypercellularity with the presence of blasts
  - Cytogenetics including the presence of Ph

Poor Prognostic Factors

- Older age
- Splenomegaly
- High percent blasts in the blood (ie, AP- or BP-CML at time of diagnosis)
- Abnormal platelet count (high or low)
- Additional chromosomal abnormalities (i.e., clonal evolution)

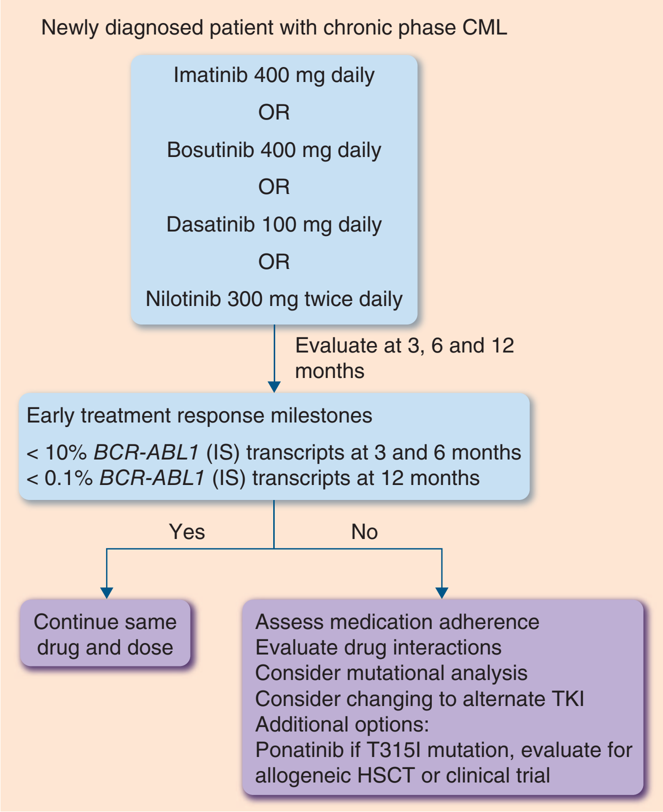
TREATMENT

Desired Outcome

The primary goal in the treatment of CML is to achieve long-term disease control with TKI therapy and possibly treatment-free remission (TFR). A deep, long-lasting molecular response is associated with long-term disease control and achievable for many patients with CP-CML through TKI therapy.[6] Most recently, TFR (i.e. TKI discontinuation) has emerged as a goal for select patients who sustain a deep molecular response while on a TKI. Treatment goals and disease progression are determined and assessed through the molecular monitoring of *BCR-ABL1* transcripts. A complete molecular response is defined as undetectable *BCR-ABL1* transcripts by the International Scale (IS).[5] International standardization of molecular response reflects a percentage of *BCR-ABL1* compared to standardized baseline.[4] Approximately 50% to 70% of patients with CML will achieve a major molecular response (<0.1% *BCR-ABL1* [IS]) and another 10% to 20% will achieve an even deeper molecular response.[6] Additional goals include achieving a complete hematologic and cytogenetic response. A complete hematologic response is defined as a normalization of peripheral blood counts and complete cytogenetic response being the elimination of Ph+ metaphases.[3] A cure from CML can only come from complete eradication of the Ph clone.

General Approach to Treatment

There have been significant advances in the treatment of CML since the discovery of the Ph in 1960. The success of therapy is largely dependent on patient adherence and the clinical phase of the disease. Treatment decisions are based on the patient age, phase of CML, and comorbidities. The National Comprehensive Cancer Network (NCCN) provides recommendations on the therapeutic treatment approach for CML.[5] Nearly all patients with CML are initially treated with a TKI. Depending on the clinical phase and *BCR-ABL* mutation profile, newer generation TKIs or omacetaxine may be options for patients who fail to respond or do not tolerate initial TKI therapy. Hydroxyurea may be used after diagnosis to rapidly reduce high white blood cell (WBC) counts and prevent potentially serious complications (respiratory and neurologic) associated with large numbers of circulating neutrophils. Hydroxyurea, though, does not alter the disease process. TKIs can also reduce peripheral WBC counts over several weeks; therefore, many patients are started on a TKI alone. Allogeneic hematopoietic stem-cell transplant (HSCT) is reserved for patients with TKI resistance. Figure 97–1 illustrates one approach for clinically managing newly diagnosed patients with CP-CML.



Newly diagnosed patient with chronic phase CML
Imatinib 400 mg daily
OR
Bosutinib 400 mg daily
OR
Dasatinib 100 mg daily
OR
Nilotinib 300 mg twice daily
Evaluate at 3, 6 and 12 months
Early treatment response milestones
< 10% BCR-ABL1 (IS) transcripts at 3 and 6 months
< 0.1% BCR-ABL1 (IS) transcripts at 12 months
Yes
No
Continue same drug and dose
Assess medication adherence
Evaluate drug interactions
Consider mutational analysis
Consider changing to alternate TKI
Additional options:
Ponatinib if T315I mutation, evaluate for allogeneic HSCT or clinical trial

FIGURE 97–1. Algorithm for TKI therapy in newly diagnosed patient with CP-CML. (Data from NCCN.)

Nonpharmacologic Therapy

▶ *Hematopoietic Stem-Cell Transplantation*

Allogeneic HSCT is the only curative treatment option for CML; however, the impressive outcomes with TKIs have limited the role of transplant. Allogeneic HSCT may be considered for the rare patient with *BCR-ABL* mutations that are resistant to or who fail TKI therapy. Transplant should also be considered for patients who present in BP-CML.[5] There are significant risks and long-term complications with allogeneic HSCT, including early mortality and graft-versus-host disease. For patients who do not achieve a complete molecular response or have disease relapse following allogeneic HSCT, the infusion of donor lymphocytes may place the patient back into a durable remission.[5]

Pharmacologic Therapy

The treatment of CML has dramatically changed since the introduction of *BCR-ABL1* TKIs. **KEY CONCEPT** Nearly all patients with CML are initially treated with a TKI. These oral agents do not cure CML but produce long-term disease control in the vast majority of patients. Four TKIs (imatinib, bosutinib, dasatinib, and nilotinib) may be used as first-line therapy for newly diagnosed CP-CML.[5] Many patients will require life-long use of TKIs. However, there is a growing body of evidence supporting the discontinuation of TKI therapy in select patients who have experienced stable molecular response for greater than 2 years (TFR).[7]

▶ *Imatinib mesylate (Gleevec)*

Imatinib mesylate (Gleevec) is a first-generation TKI and was the first TKI to show efficacy in the treatment of CML. Imatinib inhibits the phosphorylation of various proteins involved in cell proliferation by binding to the adenosine triphosphate–binding pocket of *BCR-ABL1*. The almost 11-year follow-up data shows that the use of imatinib in CP-CML results in an estimated overall survival (OS) of 83.3%, a complete cytogenetic response of 82.8%, and an estimated event-free survival of 79.6%.[8] Lower response rates are reported in accelerated phase and BP-CML.[1] However, only 48% of patients assigned to imatinib in the initial study remained on imatinib after 10 years. This was a lower percentage than expected, leading to concerns with imatinib failure/resistance (see TKI resistance) and intolerance.[8] Imatinib is generally well tolerated. Common side effects include myelosuppression, gastrointestinal disturbances, and myalgias. Dosing and additional adverse effects may be found in Table 97–1.

▶ *Advanced-Generation TKIs*

Imatinib resistance resulted in the need for advanced generation TKIs that could overcome specific mutations. Dasatinib (Sprycel), nilotinib (Tasigna), bosutinib (Bosulif), and ponatinib (Iclusig) are advanced generation TKIs that may overcome imatinib resistance or intolerance. These inhibitors are more potent than imatinib in inhibiting *BCR-ABL1*, with reports of dasatinib being 350 times and ponatinib being 520 times more potent.[1,9] The advanced generation TKIs can overcome most *BCR-ABL1* mutations. However, of the four, only ponatinib can overcome the *T315I* mutation.[5]

Bosutinib, dasatinib, and nilotinib are indicated for first-line therapy in CP-CML. Studies suggest bosutinib, dasatinib, and nilotinib are superior to imatinib in achieving faster and deeper cytogenetic and molecular responses.[10-12] Fewer patients progress to accelerated or blast phase on bosutinib, dasatinib, or nilotinib compared to imatinib, although there are no differences in OS reported between the agents. These TKIs are also generally well tolerated. Common side effects are similar to those of imatinib and may be found in Table 97–1. A significant and potentially severe side effect associated with the use of dasatinib is the development of pleural effusions. Concerning side effects of nilotinib include QT prolongation, requiring an electrocardiogram at baseline and 7 days after initiating therapy, and increases in indirect bilirubin.[5] These side effects are typically managed by treatment interruptions and/or selection of a different TKI.[8] Clinicians should be mindful of potential drug–drug interactions, since all TKIs are metabolized by cytochrome P450 3A4.[1]

Ponatinib is a third-generation multikinase inhibitor that overcomes the *BCR-ABL* domain mutation *T315I*. Ponatinib was initially approved for the treatment of patients in all phases of CML that were resistant or intolerant to prior TKI therapy. In postmarketing analysis, an increase in serious arterial thrombotic events was shown in 24% of patients.[5,9] The revised label restricts the use of ponatinib to patients harboring the *T315I* mutation or that have failed multiple prior TKIs. Arterial occlusive events are a boxed warning. Other, serious adverse effects include heart failure and liver failure.

▶ *Omacetaxine Mepesuccinate*

Omacetaxine mepesuccinate (Synribo) is a semisynthetic formulation of homoharringtonine. Omacetaxine reversibly inhibits protein synthesis, thereby causing cell death.[13] Unlike TKIs, the mechanism of action affects both normal and malignant hematopoietic cells. Omacetaxine is a subcutaneous injection indicated for patients in CP- or AP-CML who are resistant or intolerant to two or more TKIs.[5] It may also be used in patients with the *T315I* mutation. Nonhematologic adverse reactions may be found in Table 97–1. Clinicians should note omacetaxine may cause hyperglycemia that requires monitoring, which is particularly important in patients with diabetes.

▶ *TKI Resistance*

CML disease progression is typically attributed to primary or secondary TKI resistance. A common mechanism of resistance involves point mutations in the *BCR-ABL1* kinase domain. Some of these mutations are associated with poorer prognosis.[5] The *ABL* kinase mutation *T315I* is one mechanism of secondary resistance that results in reactivation of *BCR-ABL1* activity. The *T315I* mutation renders imatinib and the second-generation TKIs ineffective; therefore, alternative therapy with agents that overcome this mutation (ie, ponatinib) must be selected.[4] *BCR-ABL1* mutational analysis is recommended for any patient who does not achieve the desired response outcomes and milestones. The NCCN Guidelines can assist clinicians with selecting the most appropriate TKI based on mutational analysis.[5]

OUTCOME EVALUATION

Successful treatment for CML depends on an optimal response to TKI therapy (eg, hematologic, cytogenetic, and molecular). Nearly all newly diagnosed CP-CML patients will be placed on a TKI and will remain on TKI therapy for an indefinite amount of time. First-line treatment options include imatinib, bosutinib, dasatinib, and nilotinib. Which agent to use depends on several factors, including disease risk score, age, comorbid conditions, medication safety profile, and financial accessibility. Patients should be

Table 97–1

Drugs Used in CML

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Bosutinib (Bosulif)	Diarrhea, nausea vomiting, thrombocytopenia, neutropenia, increased liver function tests, fluid retention	Dose: 400–500 mg po once daily depending on phase Dose may be increased to 600 mg po once daily if complete hematologic response not seen at 8 weeks or complete cytogenetic response by 12 week Take with food Drug interactions: metabolized by CYP 3A4; inhibitor and substrate of P-glycoprotein	CrCl 30–50 mL/min (0.50–0.83 mL/s): 500 mg daily and may decrease to 400 mg if cannot tolerate CrCl < 30 mL/min (0.50 mL/s): 300 mg daily	Any baseline liver impairment: 200 mg daily
Dasatinib (Sprycel)	Thrombocytopenia, neutropenia, headache, rash, edema, pleural effusions	Dose: 100 mg po once daily for chronic phase CML or 140 mg po daily for accelerated phase or blast crisis Avoid concomitant medications that prolong the QT-interval; low levels of potassium and magnesium should be corrected before initiating therapy Drug interactions: metabolized by CYP 3A4 Dasatinib exhibits pH-dependent absorption; avoid medications that alter gastric pH (eg, H_2 antagonists and PPIs)	No reductions	No reductions
Imatinib mesylate (Gleevec)	Neutropenia, thrombocytopenia, diarrhea, rash, nausea, edema, fatigue, arthralgias, myalgias, headache, increased liver function tests, congestive heart failure (rare)	Dose range: 400–800 mg po per day depending on phase Take with meals and a full glass of water Drug interactions: metabolized by CYP 3A4; weak inhibitor of CYP 2D6 and 2C9 Avoid taking with acetaminophen to reduce hepatic toxicity Diarrhea usually responds to loperamide	CrCl 20–39 mL/min (0.33–0.66 mL/s): 50% reduction in dose CrCl < 20 mL/min (0.33 mL/s): use with caution	Mild to moderate impairment: no adjustment Severe impairment: reduce dose by 25% Discontinue imatinib if liver transaminases are > 5 × upper limit of normal or if serum bilirubin > 3 × upper limit of normal
Nilotinib (Tasigna)	Thrombocytopenia, neutropenia, elevated bilirubin, elevated serum lipase	Dose: 400 mg po twice daily Take on an empty stomach Black-box warning for QT prolongation; avoid concomitant medications that prolong the QT interval; low levels of potassium and magnesium should be corrected before initiating therapy Drug interactions: metabolized by CYP 3A4; competitive inhibitor of CYP 2C8, 2C9, 2D6, and UGT1A1 Pharmacogenomic testing of UGT1A1 polymorphisms can be used to identify patients who may have hyperbilirubinemia	No reductions	Child-Pugh class A, B, or C: 200 mg po twice daily for chronic phase CML; may increase to 300 mg if tolerating nilotinib therapy; discontinue nilotinib if experiencing grade 3 or 4 elevations in bilirubin or liver transaminases
Omacetaxine mepesuccinate (Synribo)	Myelosuppression, hyperglycemia	Dose: 1.25 mg/m^2 subcutaneous injection twice daily × 14 days, repeat every 28 days until hematologic response achieved Maintenance therapy: 1.25 mg/m^2 subcutaneous injection twice daily × 7 days every 28-day cycle Drug interactions: P-glycoprotein substrate	No reductions	No reductions
Ponatinib (Iclusig)	Arterial and venous thromboembolisms, hepatotoxicity, congestive heart failure, pancreatitis, gastrointestinal bleeding, fluid retention, myelosuppression, fatigue, headaches	Dose: 45 mg daily Boxed warnings for arterial occlusive events. Monitor CBC, lipase and liver function tests Drug interactions: metabolized by CYP 3A4,2C8, 2D6 competitive inhibitor of P-glycoprotein	No reductions	Child-Pugh class A, B, or C: 30 mg daily Hold ponatinib if liver transaminases are > 3 × upper limit of normal May resume but reduce dose when < 3 × upper limit of normal

CML, chronic myeloid leukemia; CrCl, creatinine clearance; po, oral; PPI, proton pump inhibitor.

Patient Encounter 1

A 38-year-old Hispanic woman presents to her primary care physician with complaints of "feeling tired over the past couple months" and "occasional abdominal pain". Her medical history consists of poorly controlled type 2 diabetes. Her A1C is 10.8% despite treatment on metformin 1 g twice daily and 30 units of glargine (weight: 100 kg). She also takes OTC omeprazole for GERD. A CBC is drawn and shows the following:

Total WBC: 104 × 10^9/L (104 × 10^3/mm^3) (5% [0.05] blasts, 75% [0.75] segs, 20% [0.20] lymphs)

Hgb/Hct: 7.7 g/dL (97 g/L; 6.014 mmol/L)/29% (0.29)

Platelets: 510 × 10^9/L (190 × 10^3/mm^3)

The patient is referred to an oncologist for further workup. A bone marrow biopsy is performed and reveals hypercellular marrow with 5% (0.05) blasts. Cytogenetics are positive for t(9:22).

What information is suggestive of CP-CML?

Which specific treatment do you recommend for initial treatment and why?

Identify your treatment goals for this patient.

What drug information and patient counseling will you provide to the patient?

Identify factors that may contribute to this patient having a suboptimal response.

Assuming this patient has a suboptimal response to your initial therapy, what would you recommend for second-line therapy?

counseled on the importance of medication adherence. Patients should understand that poorer outcomes may result if they are not adherent to daily TKI therapy. The NCCN guidelines provide response criteria.[5] Molecular responses at 3, 6, and 12 months are assessed, as the milestones are associated with improved progression-free survival (PFS) and OS. Patients failing to achieve these milestones should undergo *BCR-ABL1* domain mutation testing to determine TKI resistance and be evaluated for medication adherence and possible drug interactions. Second-line CP-CML therapy should be selected based on mutational analysis with second-generation TKIs utilized. These drugs may also be used in patients who have AP-CML. Ponatinib may be considered if the *T315I* mutational status is present with an understanding that it is associated with serious vascular effects. Omacetaxine, allogeneic stem-cell transplantation, and clinical trials are options for those patients that do not respond to or tolerate a TKI. Some patients will not respond to treatment and will progress to BP-CML where they will receive treatment for acute leukemia. Although its use is limited, allogeneic transplant offers the only cure for CML and may be useful in patients with advanced disease who have failed other options.

CHRONIC LYMPHOCYTIC LEUKEMIA

EPIDEMIOLOGY AND ETIOLOGY

CLL is the most common type of leukemia diagnosed in adults, accounting for 30% of all adult leukemias. It was estimated that in 2021, 21,250 new cases will be diagnosed in the United States.[2] The median age at diagnosis is 70 years with the incidence increasing with age.[14] The etiology of CLL is unknown, but hereditary factors may have a role. First-degree family members of CLL patients have up to an 8.5-fold increased risk of CLL.[15]

PATHOPHYSIOLOGY

Cell of Origin

CLL is characterized by small, relatively mature, yet incompetent B lymphocytes that accumulate in the blood and bone marrow over time. While the exact cell of origin remains controversial, early genetic abnormalities that impair apoptosis appear to be involved in the transformation to malignancy.[16] The lack of apoptotic mechanisms, including B-cell lymphoma 2 (BCL-2) overexpression, leads to the persistence and accumulation of B lymphocytes. Chromosomal abnormalities, such as deletions of the long arm of chromosome 13 or 11 (del(13q) or del(11q)), are

Clinical Presentation and Diagnosis of CLL

Signs and Symptoms (~50% Are Asymptomatic at Diagnosis)

- Lymphadenopathy
- Organomegaly consisting of splenomegaly and hepatomegaly
- Fatigue, weight loss, night sweats, fevers
- Chronic infections caused by immature lymphocytes

Diagnostic Procedures

- Peripheral blood smear
- Bone marrow biopsy
- Cytogenetic studies
- Molecular testing

Laboratory Findings[18]

- Peripheral blood
  - Lymphocytosis (absolute lymph count > 5 × 10^9/L [5 × 10^3/mm^3]) sustained for 3 months—required for diagnosis
  - Leukocytosis (WBC count > 100 × 10^9/L [100 × 10^3/mm^3])
  - Anemia
  - Thrombocytopenia
  - **Hypogammaglobulinemia**
- Bone marrow
  - Hypercellular with increased mature lymphocytes
- Molecular markers
  - Cytogenetic abnormalities in >80% of patients

Poor Prognostic Factors

- Lymphocytosis with accompanying:
  - Anemia (hemoglobin ≤ 11.0 g/dL [110 g/L; 6.83 mmol/L])
  - Thrombocytopenia (platelets < 100 × 10^9/L [100 × 10^3/mm^3])
  - Higher percentage of **ZAP-70**, CD49d, and CD38 antigen expression
  - Cytogenetics such as deletions of chromosomes 17p and 11q, *TP53* mutations, and unmutated *IgVH*

frequently observed in most cases of CLL and additional mutations often correlate with progressive disease.[16] Numerous kinases appear to be involved in CLL, including the activation of Bruton tyrosine kinase (BTK) and phosphoinositide 3-kinase (PI3K) delta.[17] Detection of these markers may predict clinical course and prognosis and may influence treatment decisions.

Clinical Course

CLL can have a variable clinical course with survival ranging from months to decades. Patients are classified as low, intermediate, or high risk. Approximately 90% of patients are diagnosed with asymptomatic, low-risk CLL, where the median survival times exceed 10 years.[19] The typical low-risk patient is an asymptomatic elderly patient who is diagnosed on routine blood draw. Intermediate risk is associated with lymphadenopathy and has median survival times of about 7 years. High-risk patients with anemia have median survival times of only 2 years.[20] The typical high-risk patient is a symptomatic middle-aged patient. Some patients with slightly elevated B lymphocytes may not meet the diagnostic criteria for CLL and may be diagnosed with monoclonal B-lymphocytosis (MBL). Observation is recommended for MBL instead of treatment. The progression from MBL to CLL/small lymphocytic lymphoma is between 1% and 2% per year.[21] The International Workshop on Chronic Lymphocytic Leukemia (iwCLL) has published consensus guidelines that can assist clinicians with diagnosis, indications for treatment, and response assessment.[18]

STAGING AND PROGNOSTIC FACTORS

Two staging systems, Rai and Binet, have been developed to help practitioners determine the overall prognosis of patients with CLL. They are comparable systems and useful to broadly determine good, intermediate, and poor prognostic disease.[20] Risk stratification includes both physical criteria such as lymphadenopathy, splenomegaly, and hepatomegaly, and cytopenias. Increasingly, biological markers of the disease such as deletion of chromosome 17p (del(17p)), del(11q), and mutational status of immunoglobulin heavy chain variable region gene (*IgVH*) are used to predict the likely clinical course.[20,26] These biological markers are not included in the Rai or Binet staging systems. Additionally, elevated levels of serum beta-2 microglobulin and lactate dehydrogenase are important prognostic indicators for survival.[19] Patients with del(17p) or *TP53* mutations tend to have a poor response to therapy.

TREATMENT

Desired Outcomes

The primary goals in the treatment of CLL are to provide palliation of symptoms and achieve a long-term remission. Oral kinase inhibitors have become the backbone of therapy. These drugs are continued until disease progression or unacceptable toxicity. Because the current treatments for CLL are not curative for most patients, reduction in tumor burden and improvement in disease symptoms are reasonable end points, particularly in older patients. A complete response (CR) to therapy can be defined as a resolution of lymphadenopathy and organomegaly, normalization of peripheral blood counts, and elimination of lymphoblasts in the bone marrow.

Nonpharmacologic Therapy

KEY CONCEPT Asymptomatic early-stage CLL can be observed without treatment until evidence of disease progression.[18] Past studies with chlorambucil suggest that chemotherapy does not improve OS in early-stage CLL, although there is question whether this remains true with the development of newer therapies. In addition, deferring therapy until a patient becomes symptomatic does not alter OS.[18] For this reason, the notion of "watch and wait" is considered reasonable for older patients with low risk disease. Several factors will influence this approach, including life expectancy, disease characteristics, and ability to tolerate therapy.[20]

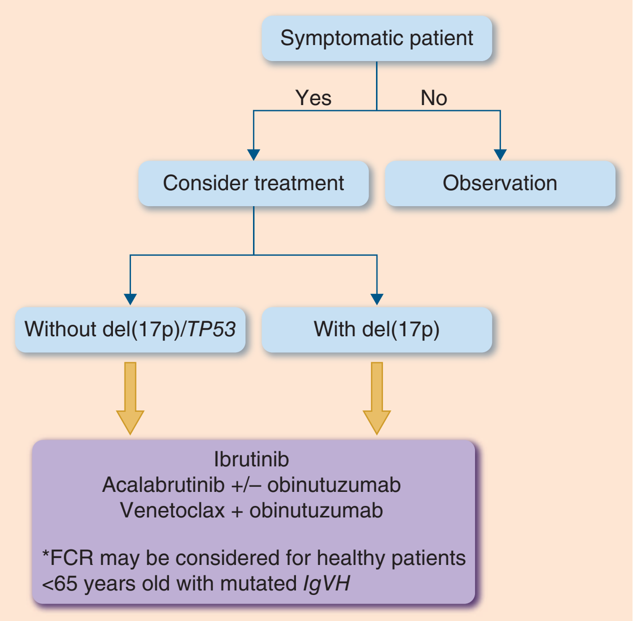
▶ *Hematopoietic Stem-Cell Transplantation*

The use of HSCT in CLL is limited. Allogeneic HSCT offers longer disease-free remissions in patients with poor prognosis than autologous HSCT but is associated with higher treatment morbidity and mortality. Several factors must be considered before pursuing allogeneic HSCT. The lack of a donor, older age, and poor performance status make transplantation an uncommon procedure in these patient populations. Allogeneic HSCT remains an option for younger patients with aggressive disease who have failed prior therapies, including small molecule inhibitor therapy.[20]

Pharmacologic Therapy

The treatment options for CLL have significantly expanded in the past decade, improving patient outcomes. Oral small molecule inhibitor therapy (eg, ibrutinib, venetoclax) has established a pivotal role in the front-line treatment of symptomatic CLL. This has minimized the use of traditional chemotherapy-based regimens (eg, purine analogs and alkylating agents). Monoclonal antibodies targeting CD20 antigen may also be incorporated into front-line therapy. The NCCN guidelines provide recommendations on first-line and subsequent CLL therapies based on mutational status, age, and whether comorbidities are present.[20]

Figure 97–2 illustrates one approach for initial therapy in newly diagnosed patients with CLL.



Symptomatic patient

*FCR may be considered for healthy patients <65 years old with mutated *IgVH*

FIGURE 97–2. Possible treatment approach for first-line therapy in newly diagnosed CLL patients. (B, bendamustine; C, cyclophosphamide; F, fludarabine; R, rituximab.) (Data from NCCN.)

▶ *Cytotoxic Chemotherapy*

Prior to the development of targeted therapy, cytotoxic chemotherapy was the mainstay for the treatment of CLL. Patients would receive either a higher or lower intensity regimen based on age, comorbidities, and their ability to tolerate the selected chemotherapy regimen. Regimens incorporating the purine analog fludarabine (Fludara) and the alkylating agents, chlorambucil (Leukeran) or cyclophosphamide (Cytoxan), were routinely used. Today, the treatment for CLL has changed with the development of newer agents. Numerous trials have shown a survival benefit with the newer agents, resulting in declined use of traditional chemotherapy.[22] However, NCCN still recommends fludarabine, cyclophosphamide, and rituximab (FCR) as the preferred regimen for younger (< 65 years old) patients with *IgVH*-mutated CLL.[20] *IgVH*-mutated CLL has a better prognosis than *IgVH*-unmutated CLL.[19] The aggressive use of FCR may offer a potential cure for these select patients. Fludarabine is associated with myelosuppression and prolonged immunosuppression. Clinicians should consider antibacterial and antiviral prophylaxis for *Pneumocystis* and herpes virus when using fludarabine-based therapy.[20]

▶ *Monoclonal Antibodies*

Anti-CD20 monoclonal antibodies are widely used in the treatment of CLL. Like most other B-cell malignancies, CLL expresses CD20 antigens. The exact function of CD20 isn't clear but CD20 appears to be involved in B-cell receptor signaling and expansion of the CLL clone.[17] Several anti-CD20 monoclonal antibodies are used in the treatment of CLL. Rituximab (Rituxan), a naked chimeric anti-CD20 monoclonal antibody, was the first approved for the treatment of CLL. Rituximab has been largely replaced by the next-generation monoclonal antibodies, obinutuzumab (Gazyva), and ofatumumab (Arzerra). The mechanism of action is complex and includes activation of complement-dependent cytotoxicity, triggering of antibody-dependent cell-mediated cytotoxicity, and direct toxicity, depending on the drug.[23] Obinutuzumab is different than the other anti-CD20 monoclonal antibodies, having a higher binding affinity to the CD20 epitope and causing direct cell death.[23] The anti-CD20 monoclonal antibodies are often used in combination with targeted therapy or chemotherapy. They are less frequently used as a monotherapy. The selection and combination of the monoclonal antibody depends on clinical studies.

The most common side effects for monoclonal antibodies include infusion reactions consisting of fever, chills, hypotension, nausea, vomiting, and headache. Premedication with diphenhydramine and acetaminophen is recommended to minimize infusion reactions. Reactivation of hepatitis B virus (HBV) is also a concern for patients on anti-CD20 therapy. Patients should be tested for hepatitis B surface antigen and hepatitis B core antibody prior to starting therapy. Prophylactic hepatitis B antiviral therapy or treatment with entecavir may be warranted. Clinicians should continue to monitor hepatitis B viral load throughout treatment, recognizing that HBV prophylaxis should be continued up to 1 year after treatment ends.[20] Table 97–2 lists additional adverse effects seen with the anti-CD20 monoclonal antibodies.

▶ *Small Molecule Inhibitors*

KEY CONCEPT An understanding of the B-cell receptor signaling pathways of CLL has led to the approval of numerous novel oral targeted therapies. Many of these therapies have had impressive results and improved the median OS of CLL.

Ibrutinib (Imbruvica) has transformed the treatment of CLL. Ibrutinib is an inhibitor of BTK, an essential enzyme in the B-cell receptor pathway. Inhibition of BTK prevents the activation of additional downstream pathways involving other kinases, including phosphatidylinositol-3-kinase (PI3-K) and nuclear factor-kappa B. These pathways are involved in cellular survival and proliferation. Ibrutinib was originally studied as a single agent in patients with relapsed CLL reporting an overall response rate of 71%, an impressive percentage for this subset of patients. Ibrutinib's indications have expanded to first-line therapy and is the preferred treatment for most patients with CLL, including patients with or without del(17p), regardless of age.[20] Ibrutinib is used as monotherapy as the addition of rituximab to ibrutinib did not improve PFS compared to ibrutinib alone.[22] Clinicians should be aware that most patients on ibrutinib experience a transient increase in absolute lymphocyte count. The lymphocytosis will persist for several weeks and then subside. Continuation of therapy is warranted and does not suggest disease progression.[17,20] An increased risk of atrial fibrillation has been also associated with ibrutinib. Additional adverse effects may be found in Table 97–2.

Acalabrutinib (Calquence) is a second-generation BTK inhibitor approved for the treatment of patients with CLL. Acalabrutinib has a higher BTK selectivity than ibrutinib which has led to promising results.[16] The indications are similar to ibrutinib with acalabrutinib being used with or without obinutuzumab for first-line therapy of CLL and in relapsed and refractory CLL. There is an ongoing head-to-head clinical trial of ibrutinib to acalabrutinib which will provide insight into the efficacy and toxicity differences.

The recognition of PI3-K's involvement in the pathogenesis of CLL has led to the development of PI3-K inhibitors. Idelalisib (Zydelig) and duvelisib (Copiktra) are oral inhibitors of PI3-K. Idelalisib has been studied as monotherapy as well as combination therapy with rituximab. Both idelalisib and duvelisib may be used for patients with relapsed/refractory CLL.[20] Boxs warnings for idelalisib and duvelisib include hepatotoxicity, for idelalisib and colitis, infestion, cutaneous reactions and pneumonitis for duvelisib.[16] Patients should receive *Pneumocystis* pneumonia prophylaxis and CMV antiviral prophylaxis should also be considered to prevent CML infection and reactivation.[20] Like the BTK inhibitors, patients may experience a transient increase in absolute lymphocyte count and continuation of therapy is warranted. Nonhematologic side effects for both drugs may be found in Table 97–2.

BCL-2 is an antiapoptotic protein overexpressed in patients with CLL.[17] Venetoclax (Venclexta) is an oral small molecular inhibitor that targets BCL-2 and may be used as first-line therapy or in relapsed/refractory CLL.[23,24] Venetoclax is used in combination with anti-CD20 monoclonal antibodies. Research continues to explore venetoclax-combination therapy and the most efficacious sequencing with BTK inhibitors. Adverse effects for venetoclax include tumor lysis syndrome, in which prophylaxis with allopurinol or rasburicase and oral hydration is recommended, and prolonged neutropenia, which may require growth factor support.[20]

OUTCOME EVALUATION

Successful outcomes depend on the appropriate treatment selection for a specific patient. Risk-versus-benefit should be determined in the treatment of older CLL patients. Because CLL is incurable, "watch and wait" is a reasonable approach for those with indolent, asymptomatic disease. Treatment can begin when the patient becomes symptomatic. Ibrutinib is the first-line

Table 97–2

Drugs Used in CLL

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Acalabrutinib (Calquence)	Opportunistic infections, hemorrhage, cytopenias, secondary malignancy, atrial fibrillation (grade 3 in 1.1%)	Dose: 100 mg po twice daily Avoid concomitant use with CYP 3A4 inhibitors/inducers Avoid administering with PPI	No reductions	Avoid in severe hepatic dysfunction
Duvelisib (Copiktra)	Boxed warnings: Serious and fatal infections, diarrhea, colitis, cutaneous reactions, pneumonitis	Dose: 25 mg po twice daily Avoid concomitant use with CYP 3A4 inducers. Reduce dose when administered with strong CYP 3A4 inhibitors	No reductions	No reductions
Fludarabine (Fludara)	Myelosuppression; prolonged immunosuppression, resulting in secondary infectious complications; edema; neurotoxicity	Dose: 20 mg/m^2 IV daily for 5 days Often given in combination	CrCl 30–70 mL/min (0.50–1.17 mL/s): 20% reduction of dose (IV and po) CrCl < 30 mL/min (0.50 mL/s): do not use IV; reduce dose of oral by 50%	No reductions
Ibrutinib (Imbruvica)	Opportunistic infections, hemorrhage, cytopenias, secondary malignancy, atrial fibrillation (grade 3 in 4%), hypertension, TLS	Dose: 420 mg po once daily Avoid the use of concomitant CYP 3A4 inhibitors/inducers Drug metabolism: CYP 3A4 and 2D6	No reductions in CrCl > 25 mL/min (0.42 mL/s) Insufficient data in < 25 mL/min (0.42 mL/s)	Insufficient data exists; interruption if hepatotoxicity occurs
Idelalisib (Zydelig)	Boxed warnings: severe hepatotoxicity, diarrhea, colitis, pneumonitis, intestinal perforation Serious allergic reactions	Given in combination with rituximab Dose: 150 mg po twice daily Drug metabolism: CYP 3A4; strong inhibitor of 3A4, 2C8, 2C9, 2C19	No reductions in CrCl > 15 mL/min (0.25 mL/s) Insufficient data in < 15 mL/min (0.25 mL/s)	Insufficient data exists
Obinutuzumab (Gazyva)	Infusion reactions, reactivation of hepatitis B, progressive multifocal encephalopathy, TLS, neutropenia	Premedicate with acetaminophen, IV antihistamine, and an IV steroid to alleviate infusion-related reactions Consider antimicrobial, antiviral, and antifungal prophylaxis Hold antihypertensives 12 hours prior, during, and after due to the risk of hypotension	No reductions in CrCl > 30 mL/min (0.50 mL/s) Insufficient data in < 30 mL/min (0.50 mL/s)	No reductions
Ofatumumab (Arzerra)	Severe infusion reactions: bronchospasm, edema, fever, chills, rigors, hypotension; prolonged myelosuppression	Premedicate with acetaminophen, IV antihistamine, and an IV steroid to alleviate infusion-related reactions Rate of infusion should be increased gradually to minimize reactions Monitor for reactivation of hepatitis B	No reductions	No reductions
Rituximab (Rituxan)	Infusion reactions: fever, chills, rigors, hypotension	Premedicate with acetaminophen, diphenhydramine with or without a steroid to alleviate infusion related reactions Rate of infusion should be increased gradually to minimize reactions Monitor for reactivation of hepatitis B	No reductions	No reductions
Venetoclax (Venclexta)	TLS requiring hydration and anti-hyperuricemics, neutropenia, thrombocytopenia, infections	Initial dose: 20 mg po once daily × 7 days; then increased weekly over 5 weeks to a max dose of 400 mg po once daily Drug metabolism: do not coadminister with a strong CYP3A inhibitor and caution with strong/moderate CYP3A inducers	No reductions in CrCl > 30 mL/min (0.50 mL/s) Insufficient data in < 30 mL/min (0.50 mL/s)	No reductions for mild to moderate; insufficient data exists for severe

CrCl, creatinine clearance; IV, intravenous; po, oral; PCP, pneumocystits pneumonia; PPI, proton pump inhibitor; TLS, tumor lysis syndrome.

Patient Encounter 2

Your patient is a 54-year-old man presents to his healthcare provider with complains of a "lump in his neck". Medical history includes well-controlled hypertension and benign prostatic hypertrophy. Physical examination reveals cervical lymph node enlargement and splenomegaly. Blood work reports the following:

WBC: 30×10^9/L (30×10^3/mm^3)

Hgb: 8.2 g/dL (112 g/L; 6.944 mmol/L)

Platelets: 182×10^9/L (18.2×10^3/mm^3)

Peripheral Smear: Lymphocytosis with small, mature-appearing cells suggestive of chronic lymphocytic leukemia

FISH analysis: del(13q)

***IgVH* analysis:** mutated (>2%)

Identify your treatment goals for this patient.

How does the IgHV mutation influence your treatment approach?

What treatment do you recommend and what would you monitor?

How would your treatment change if the patient had a del(17p) mutation?

Would your treatment options change if this patient were asymptomatic? If so, what would be your new treatment?

therapy for most patients, regardless of age. A desirable response to therapy includes a reduction in lymphocytes, decrease in stage of the disease, and resolution of symptoms. Supportive care, including herpes virus and *Pneumocystis* prophylaxis, may be required depending on the treatment chosen.

MULTIPLE MYELOMA

Multiple myeloma (MM) is a malignancy of the plasma cell and characterized by an abnormal production of a monoclonal protein in the bone marrow. Features of the disease include bone lesions, anemia, and renal insufficiency. MM is an incurable disease; however, advancements in the treatment of myeloma have significantly extended survival.

EPIDEMIOLOGY AND ETIOLOGY

MM is the second most common hematologic malignancy. It is estimated that approximately 34,920 new cases would be reported in 2021, accounting for approximately 2% of all cancers.[2,24] The median age at diagnosis is 69 years, and fewer than 2% are diagnosed before the age of 40 years.[24] The incidence of MM is two times higher in African Americans compared to Caucasians and occurs slightly more frequently in men than women.[25] The etiology of MM remains largely unknown although exposure to environmental factors such as ionizing radiation and agricultural pesticides has been proposed.[26]

PATHOPHYSIOLOGY

The pathogenesis of MM is quite complex with multiple-step models created to postulate the process. Myeloma must be distinguished from a condition called monoclonal gammopathy of unknown significance (MGUS), which is characterized by a

Clinical Presentation and Diagnosis of Multiple Myeloma

Signs and Symptoms

- **KEY CONCEPT** Multiple myeloma defining events ("CRAB")
  - "C"—hyperCalcemia
  - "R"—Renal failure (serum creatinine > 2 mg/dL [177 μmol/L])
  - "A"—Anemia (fatigue)
  - "B"—Bone disease (pain, lesions, fractures)
- Weight loss
- Recurrent infections

Diagnostic Procedures

Diagnosis requires at least one myeloma defining event and ≥ 10% clonal bone marrow plasma cells.

- Laboratory
  - CBC, chemistry panel, β_2-microglobulin
  - Peripheral blood smear
  - Serum protein electrophoresis and immunofixation
  - Urine protein electrophoresis and immunofixation
  - Serum free light chains
- Radiologic evaluation (low-dose CT scan or MRI)
- Bone marrow biopsy
- Cytogenetic studies
- Molecular testing

Laboratory Findings

- Peripheral blood
  - Monoclonal protein (M protein) in serum (usually IgG or IgA)
  - High **β_2-microglobulin**
  - Low platelets and hemoglobin
  - High creatinine, urea, lactate dehydrogenase, C-reactive protein, and calcium
  - Rouleaux formation
- Urinalysis
  - Urinary free light chains (**Bence-Jones Protein**)
- Bone marrow
  - Plasma cells (10% or more)
  - Abnormal cytogenetics
- Radiologic findings
  - Bone lesions, fractures, osteoporosis

Poor Prognostic Factors

- High serum β_2-microglobulin and low serum albumin
- Elevated C-reactive protein
- Elevated lactate dehydrogenase
- IgA isotype
- Low platelet count
- High-risk cytogenetics such as t(4;14), t(14;16), and del(17p)

monoclonal immunoglobulin without malignant plasma cells, and smoldering myeloma (SMM), which lacks clinical manifestations from the high monoclonal immunoglobulin. Yearly, about 1% of patients with MGUS will progress to MM. The risk of progression from SMM to MM is higher, with approximately 10% progressing per year for the first 5 years.[27] Chromosomal abnormalities and changes in gene expression appear to be involved early in the disease process and are associated with disease progression. These genetic changes lead to cell cycle dysregulation, with certain cytogenetic characteristics associated with a higher risk of transformation (ie, translocation of 4 and 14).[27] The pathophysiology of MM involves a complex bone marrow microenvironment and cytokine interactions. Interleukin-6, tumor necrosis factor, vascular endothelial growth factor, and stromal-derived factor-1 support the establishment and proliferation of myeloma cells.[28] The understanding of these interactions has led to novel agents used in the treatment of MM.

PROGNOSTIC FACTORS

Prognostic factors for myeloma include tumor, and patient related factors. The Revised International Staging System for Multiple Myeloma is used for clinical staging.[29] Staging is stratified based on the levels of serum β_2-microglobulinemia, serum albumin, and incorporates high-risk cytogenetics. High β_2-microglobulinemia and low albumin are poor prognostic factors and indicative of high tumor load.[29] The Mayo Stratification for Myeloma and Risk-Adapted Therapy (mSMART) classification may also be used to determine a treatment approach.[30,31] mSMART incorporates tumor biology to stratify patients according to their disease risk. Chromosomal changes are used to predict high-risk patients with perhaps the most important being translocations of chromosome 14 with chromosome 4, 16, or 20.[31,32] Double or triple hit myeloma (eg, multiple high-risk genetic abnormalities.), older patients, renal impairment, and other comorbidities also predict poorer outcomes.

TREATMENT

Desired Outcomes

The primary goal in the treatment of MM is to prolong PFS and OS while minimizing complications associated with the disease. A "watch and wait" approach is an option for patients with SMM since it may be years before disease progression (eg, symptomatic disease).[32] When symptoms occur, treatment is required. The treatment of MM includes primary therapy, transplantation, and maintenance therapy. All patients should be evaluated early on to see if they are transplant candidates. Autologous stem-cell transplantation prolongs OS in patients who can tolerate high-dose chemotherapy. Regardless of transplant eligibility, all patients will be placed on primary therapy to reduce tumor burden. Since most patients will progress despite primary therapy and transplantation, maintenance therapy, often with lenalidomide, is used to prolong the duration of response. Almost all patients eventually become refractory to primary treatment, requiring the use of numerous salvage therapies. Figure 97–3 illustrates possible treatment approaches for transplant-eligible and transplant-ineligible patients.

Patient Encounter 3, Part 1

A 68-year-old woman presents to the emergency room after a fall in her home. Her medical history includes controlled hypertension and osteoporosis. She notes severe bilateral hip pain. Workup reveals:

Radiology: X-ray of right and left hips: Pathologic fracture of right hip; Osteolytic lesions in both right and left hip

Labs: Hemoglobin: 8.4 g/dL (84 g/L; 5.208 mmol/L); platelets: 220×10^9/L (220×10^3/mm^3); corrected calcium: 11.8 mg/dL (2.95 mmol/L); serum creatinine: 2.3 mg/dL (203 μmol/L); serum IgG: 6200 mg/dL (42 g/L) (normal: 620–1500 mg/dL) (6.2–15 g/L); serum IgM: 80 mg/dL (8 g/L) (normal: 50–200 mg/dL [0.5–2 g/L]); bone marrow: 72% plasma cell infiltrates

What signs and symptoms are suggestive of multiple myeloma?

Nonpharmacologic Therapy

▶ *Autologous Hematopoietic Stem-Cell Transplantation (HSCT)*

KEY CONCEPT Autologous HSCT results in higher response rates, extends PFS, and improves median OS by 12 months compared with those who receive conventional chemotherapy alone.[25] The exact timing of transplant continues to be examined. Recent data suggests early autologous HSCT may have improved PFS but timing has not translated to a difference in OS.[25] Autologous HSCT remains the standard of care and should be considered in all patients who can tolerate high-dose chemotherapy. High-dose melphalan is the most common preparative regimen. Multiple randomized trials examining two sequential transplants (tandem transplants) have reported inconclusive results.[25] Thus, tandem transplantation may be considered for relapsed disease or in the setting of a clinical trial. Maintenance therapy, consisting of lenalidomide, bortezomib, or ixazomib, can be used after autologous transplantation to extend PFS.[32,33]

Pharmacologic Therapy

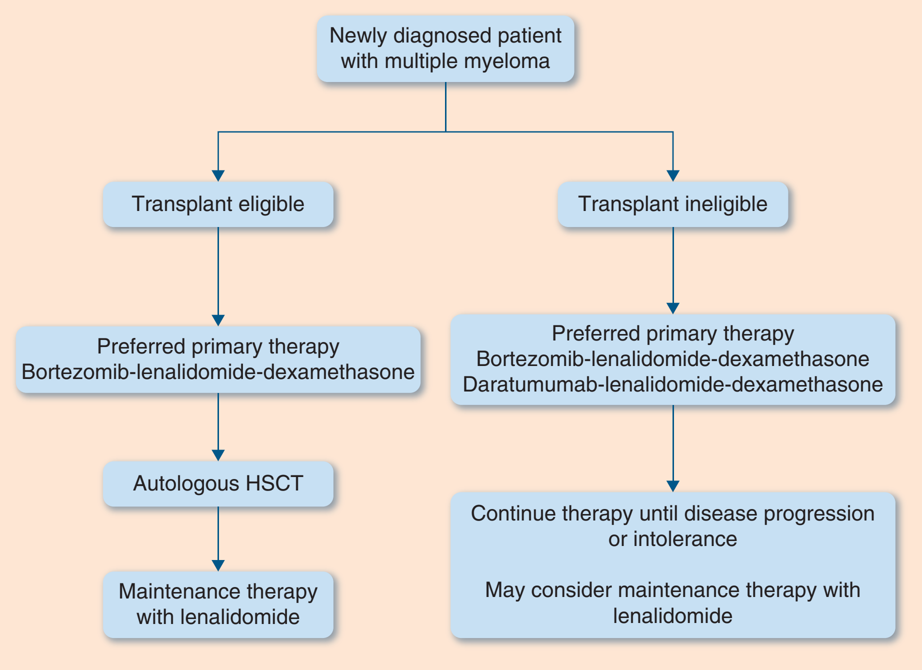
Symptomatic MM requires pharmacologic treatment. There have been numerous drugs approved in the last 15 years, changing the pharmacological management of MM. There are four main classes of drugs used in the treatment of MM: immunomodulatory agents, proteasome inhibitors, corticosteroids, and monoclonal antibodies. A three-drug regimen is often utilized in the treatment of MM. See Table 97–3.

▶ *Conventional-Dose Chemotherapy*

The use of conventional-dose chemotherapy with alkylating agents or anthracyclines has declined with the advent of immunomodulators and proteasome inhibitors, especially in the first-line setting. Cyclophosphamide or doxorubicin may be incorporated into selected treatment regimens. The regimen of cyclophosphamide, bortezomib, and dexamethasone (CyBorD) is commonly used as primary therapy in patients presenting with acute renal dysfunction.[32]

▶ *Corticosteroids*

Dexamethasone is incorporated into almost all MM treatment regimens to improve outcomes. Clinicians should recognize the daily dose of dexamethasone is often higher than the dose used in the treatment of other diseases (eg, 40 mg/day on specified days).[34] The higher doses of dexamethasone may increase the risk of infections and central nervous system toxicities. Short-term antibiotic prophylaxis at diagnosis may be warranted for those patients at high risk for infection.



Newly diagnosed patient with multiple myeloma
Transplant eligible
Transplant ineligible
Preferred primary therapy Bortezomib-lenalidomide-dexamethasone
Preferred primary therapy Bortezomib-lenalidomide-dexamethasone Daratumumab-lenalidomide-dexamethasone
Autologous HSCT
Continue therapy until disease progression or intolerance
May consider maintenance therapy with lenalidomide
Maintenance therapy with lenalidomide

FIGURE 97–3. Possible treatment approach for a newly diagnosed patient with multiple myeloma. (HSCT, hematopoietic stem-cell transplantation.) (Data from NCCN.)

▶ *Immunomodulatory Drugs*

KEY CONCEPT Immunomodulary agents are the backbone of most myeloma regimens. The immunomodulatory drug lenalidomide (Revlimid) is often used in combination therapy for the treatment of MM. The precise mechanism of action is unknown, but lenalidomide's antimyeloma activity may be attributable to its antiangiogenic and anticytokine properties.[35] Response rates are improved when an immunomodulatory agent is added to a treatment regimen.

Thalidomide was the first immunomodulatory agent to be studied with impressive responses (87%) in combination with a steroid and bortezomib.[36] Today lenalidomide has largely replaced thalidomide due to high potency and a more favorable safety profile over thalidomide.[32] The combination of bortezomib, lenalidomide, and dexamethasone (VRd) has emerged as one of the most commonly used primary regimens in the treatment of newly diagnosed, transplant-eligible, and transplant-ineligible patients with MM.[25,32] Low-dose dexamethasone (40 mg once per week) with lenalidomide offers improved OS compared with high-dose dexamethasone (40 mg on days 1–4, 9–12, and 17–20 of each 28-day cycle).[32] Lenalidomide and dexamethasone may also be used in combination with other proteasome inhibitors or daratumumab. Lenalidomide lacks many of the common side effects seen with thalidomide, although all immunomodulatory drugs are considered teratogenic based on the known teratogenicity of thalidomide. Significant adverse effects of lenalidomide include myelosuppression and VTEs. VTE prophylaxis is recommended in patients at high risk for thrombosis.[32] For transplant-eligible patients, stem cells should be collected shortly after starting lenalidomide because CD34-positive stem-cell counts tend to decrease with prolonged lenalidomide exposure. Maintenance lenalidomide after autologous HSCT is also widely utilized. Although maintenance lenalidomide therapy has been associated with an increase in PFS, there has also been an increase in the incidence of secondary malignancies.[37]

Pomalidomide is a newer, more potent immunomodulatory drug that is approved for use in patients who have progressed on two or more prior therapies.[32]

▶ *Proteasome Inhibitors*

Bortezomib (Velcade), carfilzomib (Kyprolis), and ixazomib (Ninlaro) are proteosome inhibitors approved for the treatment of MM. Proteosome inhibitors induce myeloma cell death by modulating nuclear factor kappa-B products, including inflammatory cytokines and adhesion molecules that support myeloma cell growth.[36] These drugs also disrupt the myeloma microenvironment by inhibiting the binding of myeloma cells to the bone marrow stromal cells.[36] Bortezomib-based regimens are frequently used as primary therapy for MM. The response rates with bortezomib have been reported as high as 97% in newly diagnosed myeloma.[36] Bortezomib has also shown impressive outcomes in patients with high risk disease, making it a preferred agent for these patients.[31] Adverse effects of bortezomib include fatigue, nausea, peripheral neuropathy, and hematologic effects.[36] Subcutaneous bortezomib is the preferred route of administration, offering convenience over IV access and lower risk of peripheral neuropathy with no difference in OS.[32] The incidence of VTE is lower than the immunomodulators; thus, bortezomib does not routinely require prophylactic anticoagulation. However, prophylactic antiviral therapy should be considered to reduce the risk of herpes zoster reactivation.[32]

Carfilzomib and ixazomib are second-generation proteasome inhibitors used in the treatment of MM. While carfilzomib is administered intravenously, ixazomib is the first oral proteasome inhibitor that may be given in an all orally administered regimen with lenalidomide and dexamethasone. The adverse effect profiles of carfilzomib and ixazomib are similar to bortezomib with potentially less neurotoxicity. Clinicians should note that carfilzomib requires monitoring for cardiac and pulmonary toxicities.

Table 97–3

Drugs Used in Multiple Myeloma

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Bortezomib (Velcade)	Constipation; decreased appetite; asthenia; fatigue; fever; thrombocytopenia; dose related, reversible peripheral neuropathy	Dose: 1.3 mg/m^2 IV bolus or subQ twice weekly for 2 weeks; week 3 off; repeat Concentration for IV is 1 mg/mL and 2.5 mg/mL for SC Consider herpes zoster prophylaxis with daily acyclovir	No reductions	Bilirubin > 1.5 × the upper limit of normal: reduce dose to 0.7 mg/m^2
Carfilzomib (Kyprolis)	Neutropenia, thrombocytopenia, cardiac toxicity including cardiac arrest, congestive heart failure, infusion reactions, TLS	Dose: 20 mg/m^2 IV bolus on days 1, 2, 8, 9, 16, and 16; days 17–28 off; repeat every 28 days Patients with a BSA greater than 2.2 m^2 should have dose calculated based on 2.2 m^2 Premedicate with dexamethasone 4 mg to reduce infusion-related reactions Hydration with normal saline prior to carfilzomib is recommended	No reductions	May need to dose reduce or hold dose depending on degree of hepatic dysfunction
Daratumumab (Darzalex)	Infusion reactions, diarrhea, nausea, vomiting, respiratory concerns including cough and dyspnea, infection	Dose: 16 mg/kg IV or 1800 mg subQ weekly on weeks 1–8, every other week starting week 9–24 and every 4 weeks starting week 25 Premedicate with acetaminophen, steroid, and antihistamine to reduce infusion-related reactions Bronchodilators may be needed Antiviral prophylaxis should be initiated and continued for 3 months post-last dose Corticosteroid should be started for 2 days following each infusion	No reductions	Mild/moderate: No reductions Severe: Insufficient data exists
Dexamethasone	Hyperglycemia, edema, adrenal cortical insufficiency	Dose given po once daily	No reductions	No reductions
Elotuzumab (Empliciti)	Infusion reactions, infections including opportunistic, diarrhea, secondary malignancies	Given in combination with lenalidomide and dexamethasone Premedicate with acetaminophen, ranitidine, diphenhydramine and dexamethasone to reduce infusion-related reactions	No reductions	Mild: No reductions Moderate/severe: Insufficient data exists
Ixazomib (Ninlaro)	Neutropenia, thrombocytopenia, rash, peripheral neuropathy, drug-induced hepatotoxicity	Dose: 4 mg po on days 1, 8, and 15 in combination with lenalidomide 25 mg po on days 1–21 and dexamethasone 40 mg po on days 1, 8, 15, and 28. Repeat every 28-day cycle Thromboprophylaxis is recommended with this regimen	CrCl > 30 mL/min (0.50 mL/s): no adjustments CrCl < 30 mL/min (0.50 mL/s): reduce dose to 3 mg	Mild: no reductions Moderate/severe: reduce dose to 3 mg
Lenalidomide (Revlimid)	Possible birth defects neutropenia, thrombocytopenia, DVT, PE, pruritus, fatigue	Dose: 25 mg taken with water once daily Women of childbearing age must use two forms of contraception Pregnancy test must be taken before and during use Enrollment into monitoring program required	CrCl 30–60 mL/min (0.50–1.00 mL/s): 10 mg/day CrCl < 30 mL/min (0.50 mL/s): 15 mg every 48 hours Dialysis and CrCl < 30 mL/min (0.50 mL/s): 5 mg every 24 hours given after dialysis	No reductions
Pomalidomide (Pomalyst)	Severe birth defects, DVT, neutropenia	Dose: 4 mg po daily on days 1–21; off 21–28 and repeat Drug metabolism: CYP 1A2 and 3A4	Do not use if SCr > 3 mg/dL (265 μmol/L)	Do not use if bilirubin > 2 mg/dL (34 μmol/L) and AST/ALT > 3 × the upper limit of normal
Thalidomide (Thalomid)	Severe birth defects, peripheral neuropathy, DVT, somnolence, constipation	Titrate initial doses; doses are taken nightly Women of childbearing age must use two forms of contraception Pregnancy test must be taken before and during use Enrollment into monitoring program required	No reductions	No reductions

DVT, deep venous thrombosis; IV, intravenous; PE, pulmonary embolism; po, oral; subQ, subcutaneous, TLS, tumor lysis syndrome.

▶ *Monoclonal antibodies*

Monoclonal antibodies are also incorporated into the treatment of MM. Daratumumab (Darzalex) and, most recently, isatuximab-irfc (Sarclisa) target CD38, which is a glycoprotein highly expressed on MM cells.[38] A novel formulation of daratumumab was recently approved allowing for subcutaneous administration, significantly shortening infusion times. Elotuzumab (Empliciti) has a different mechanism of action and is directed against signaling lymphocytic activation molecular F7 (SLAMF7), which is also expressed on MM cells.[25] Daratumumab is a preferred regimen used in combination with lenalidomide and dexamethasone for nontransplant eligible candidates. Additional combinations include use with bortezomib and in the quad-drug regimen, daratumumab, bortezomib, thalidomide, dexamethasone, used as primary therapy in transplant-eligible candidates. Elotuzumab and isatuximab-irfc are less frequently used, reserved for use in the treatment of relapsed disease. Patients receiving monoclonal antibodies should receive premedications to lessen the risk of infusion reactions. Herpes-zoster prophylaxis is recommended for elotuzumab and daratumumab.[32]

▶ *Additional Agents*

Several drugs continue to be explored for the treatment of relapsed/refractory myeloma. Panobinostat (Farydak) is an inhibitor of histone deacetylase and used in various combinations. Panobinostat has boxed warnings consisting of ischemic events, arrhythmias, and severe diarrhea.[32] Another agent recently receiving accelerated FDA approval is selinexor (Xpovio). Selinexor is an oral drug, blocking the cellular protein XPO1, and is reserved for patients who have failed at least four prior MM therapies.[39]

▶ *Bone-Modifying Agents*

Bone disease is a common manifestation of MM. Bisphosphonates or denosumab should be initiated in symptomatic patients with bone lesions to slow osteopenia and reduce the fracture risk associated with the disease. Pamidronate 90 mg and zoledronic acid 4 mg have equivalent efficacy in the management of osteolytic lesions.[32] The use of zoledronic acid decreases pain and bone-related complications and improves quality of life. Denosumab 120 mg Q4 weeks is also frequently used, as it is noninferior to zoledronic acid 4 mg Q4 weeks in delaying time to first skeletal event.[40] Denosumab is preferred in patients with renal insufficiency, which is often observed in patients with MM.[40] Osteonecrosis of the jaw is a major concern with bone-modifying therapy. Risk factors are unclear, but osteonecrosis of the jaw is more common in patients receiving IV administration of bisphosphonates and having dental procedures performed. It is recommended that patients have dental restoration work before starting therapy. Updated consensus guidelines have been published on the use of bone-modifying agents and myeloma, which recommend that bone-modifying agents be continued for up to 2 years.[41]

Patient Encounter 3, Part 2

The patient was diagnosed with multiple myeloma.

What treatment options are available for this patient?

What is a primary consideration when determining first line treatment?

What would be an appropriate regimen for primary therapy?

What may be used for maintenance therapy after an autologous stem-cell transplantation?

OUTCOME EVALUATION

Newly diagnosed, asymptomatic patients with MM may be observed without treatment. This asymptomatic period may last for months to several years. All patients with MM become symptomatic, and when this occurs, treatment is required. All patients should be evaluated for an autologous stem-cell transplant. Primary therapy, regardless of transplantation, often consists of bortezomib lenalidomide, and dexamethasone. Maintenance therapy with lenalidomide or bortezomib may be used, depending on risk. Nearly all patients will experience disease progression, requiring additional therapy. There are numerous treatment options for relapsed and refractory MM. Bisphosphonates or denosumab should be given to patients who have bone lesions with the hope of reducing pain and fractures.

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements.
- Review medical history, including patient's age, comorbid conditions, and current medications to avoid drug–drug interactions.
- Review laboratory values and physical assessment findings.

Assess the Information:

- Determine whether the patient requires immediate treatment based on laboratory values, physical assessment, and medical history.
- Identify whether the patient is taking any medications that could interact with the possible treatment selections for the given cancer.
- Discuss with the patient the financial costs of the possible treatment and determine if one agent is more cost-effective than another.
- If goals are not achieved, assess whether a change in medication is warranted or if nonadherence is suspected.
- If the patient experiences intolerance to therapy including any severe adverse effects, a change in medication may be warranted.

(*Continued*)

Patient Care Process (*Continued*)

Develop a Care Plan:

- Select the most appropriate treatment based on the assessment findings for the patient.
- Consider whether additional supportive care medications are needed such as prophylactic antimicrobials, growth factors, or anticoagulants.
- Discuss the importance of medication adherence and long-term outcomes.
- Address any concerns about the selected medication including cost and management of adverse effects.
- Identify the required monitoring and determine treatment outcomes and goals.

Implement the Care Plan:

- Educate the patient on the selected drug therapy, medication administration, importance of adherence, potential adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about the selected drug therapy and its management.

Follow-up: Monitor and Evaluate:

- Drug therapy should be frequently monitored to assess treatment efficacy and safety.
  - For CML, follow-up should be scheduled every 3 months to determine whether molecular, cytogenetic, and hematologic goals of therapy are being met.
  - For CLL, follow-up should include a review of symptoms and laboratory findings including lymphocytes and hemoglobin.
  - For MM, monitor myeloma monoclonal protein in urine and serum, renal function, hemoglobin, and platelets.
- Review medication adherence.
- If patients continue to have disease progression or have relapsed disease, another regimen should be utilized.
- Out of office follow-up (ie, phone calls) may be helpful to reinforce the importance of adherence and identify and manage any adverse effects.

List of Abbreviations

AP	Accelerated phase
BCL-2	B-cell lymphoma 2
BP	Blast phase/crisis
BTK	Bruton tyrosine kinase
CLL	Chronic lymphocytic leukemia
CML	Chronic myelogenous leukemia
CP	Chronic phase
CR	Complete response
FISH	Fluorescence in situ hybridization
HBV	Hepatitis B virus
HSCT	Hematopoietic stem-cell transplantation
MBL	Monoclonal B-lymphocytosis
MGUS	Monoclonal gammopathy of unknown significance
MM	Multiple myeloma
OS	Overall survival
Ph	Philadelphia chromosome
PFS	Progression-free survival
PI3-K	Phosphatidylinositol-3-kinase
qPCR	Quantitative polymerase chain reaction
SMM	Smoldering myeloma
TFR	Treatment-free remission
TKI	Tyrosine kinase inhibitor
WBC	White blood cell

98 Hematopoietic Stem-Cell Transplantation

Gianni Scappaticci and David G. Frame

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the rationale for using hematopoietic stem-cell transplant (HCT) to treat cancer, immune disorders, or hemoglobinopathies.
2. Compare the different types of HCTs, specifically (a) the types of donors (ie, autologous and allogeneic), (b) the source of hematopoietic cells (ie, peripheral blood progenitor cells, bone marrow, and umbilical cord blood), and (c) the type of preparative regimen (ie, myeloablative and nonmyeloablative).
3. Develop a plan for monitoring and managing engraftment of hematopoiesis and potential complications of engraftment.
4. List the nonhematologic toxicity to high-dose chemotherapy used in myeloablative preparative regimens, specifically busulfan-induced seizures, hemorrhagic cystitis, gastrointestinal toxicities, and sinusoidal obstruction syndrome.
5. Explain graft-versus-host disease (GVHD) including pathophysiology, differences between acute and chronic, and grading of acute GVHD.
6. Recommend a prophylactic and treatment regimen for GVHD.
7. Choose a regimen to minimize the risk of infectious complications in HCT patients.
8. Evaluate the long-term health care of HCT survivors.

INTRODUCTION

KEY CONCEPT Hematopoietic stem-cell transplant (HCT), which is often referred to as bone marrow transplant (BMT), involves the administration of CD34+ hematopoietic stem cells (HSCs) into a recipient with damaged, dysfunctional, or depleted HSCs and immune cells after administration of a preparative (or conditioning) regimen of chemotherapy, radiotherapy, or both.[1] While this process is a life-saving procedure most often used in malignant conditions, it may be used to replace dysfunctional immune deficiency syndromes like severe combined immunodeficiency syndrome (SCID), hemoglobinopathies such as sickle cell anemia, and other disorders such as scleroderma, an autoimmune disorder.[2] **KEY CONCEPT** There are two main types of HCTs, autologous HCT where the recipient receives their own HSCs and an allogeneic HCT where the recipient receives HSCs from either a related or unrelated donor (URD). Hematopoietic stem cells may be obtained from bone marrow (BM), peripheral blood progenitor cells (PBPCs), or umbilical cord blood (UCB). BM and PBPCs contain pluripotent stem cells and postthymic lymphocytes, which are responsible for long-term hematopoietic reconstitution (engraftment) and immune recovery.[1]

The rationale of an autologous HCT for a malignant condition is to administer high doses of chemotherapy to maximize therapeutic activity against the cancer and then “rescue” the BM with the patient’s own HSCs. This high-dose therapy, called the conditioning (or preparative) regimen, results in ablation of the cells in the BM. HSCs are collected from the patient prior to administering the high-dose chemotherapy and then are reinfused after the chemotherapy as a rescue to restore hematopoiesis. Allogeneic HCTs use HSCs from another donor to both rescue the recipient after chemotherapy and to generate a new immune system which can develop an immunologic response toward the recipient’s residual tumor, called the graft-versus-tumor (GVT) or graft-versus-leukemia (GVL) effect, or may replace the recipients dysfunctional immune system or hemoglobinopathy.[3] Unfortunately, this new immune system may also generate an immunologic response toward the recipient’s normal tissue causing an immune condition known as graft-versus-host disease (GVHD). It is important to distinguish that the main purpose of an autologous transplant is to deliver high-dose chemotherapy and the cells are just a rescue, while the main purpose of the allogeneic transplant is to develop an immune response against the malignancy or to replace a defective immune process or hemoglobinopathy.

The type of HCT performed depends on a number of factors, including the type and status of disorder, availability of a compatible donor, patient age, performance status, and organ function. Examples of disorders treated with HCT are listed in Table 98–1.

While outcomes of HCTs have improved significantly over the years, the field still faces the highest mortality from relapsed primary disease as well as severe GVHD.[4] New strategies including maintenance therapies after transplant to decrease relapse rates and new therapies based on better understanding of the pathophysiology of GVHD have emerged continuing to advance clinical outcomes through better pharmacotherapy.

Table 98–1

Diseases Commonly Treated with HCT

	Autologous Graft	Allogeneic Graft
Cancers	Multiple myeloma Non-Hodgkin lymphoma Hodgkin disease Neuroblastoma Germ-cell tumors	Acute myeloid leukemia Acute lymphoblastic leukemia Chronic myeloid leukemia Myelodysplastic syndrome Myeloproliferative disorders Non-Hodgkin lymphoma Hodgkin disease Chronic lymphocytic leukemia Multiple myeloma
Other Diseases	Autoimmune diseases Amyloidosis	Aplastic anemia Paroxysmal nocturnal hemoglobinuria Fanconi anemia Thalassemia major Sickle cell anemia Severe combined immunodeficiency Inborn errors of metabolism

With more patients living longer, it is important that long-term complications be addressed in a multidisciplinary approach after HCT. Many patients have multiple long-term complications which can include issues relating to several organs including cardiology, renal, hepatic, endocrine, and pulmonary as well as poor bone health, infections, and secondary malignancies.[5]

EPIDEMIOLOGY AND ETIOLOGY

In 2018, approximately 14,000 autologous HCTs and 9000 allogeneic HCTs were performed in the United States and over 50,000 HCTs are performed worldwide.[4] The most common indications for autologous HCT were multiple myeloma (MM) and lymphoma while the most common indications for allogeneic HCTs were acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). The annual number of transplants continues to steadily increase due to the use of alternative donors, the use of transplant expanding to older patients, and the use of transplants for nonmalignant conditions.[4]

The ability to collect stem cells from peripheral blood by the use of apheresis has made this a much easier and safer procedure for both autologous patients and allogeneic donors and has greatly increased the numbers of individuals willing to participate in donor marrow programs such as the National Marrow Donor Program. In the United States, URD recipients account for approximately 50% of allogeneic HCTs while human leukocyte antigen (HLA) identical siblings and transplants using “other relatives” account for approximately 22% each and UCB approximately 5%.[4] The rise in “other relatives” as donors has increased exponentially since 2014 with the onset of haploidentical transplants, which allows for more immunologically diversity and may be a donor that is a parent or child or only partially matched sibling.[4]

PATHOPHYSIOLOGY

Autologous HCT, or infusion of a patient’s own HSCs, allows for the administration of high doses of chemotherapy, radiation, or both to treat the malignancy or autoimmune disorder. In this setting, the sole purpose of the hematopoietic cells is to “rescue” the recipient’s BM from otherwise dose-limiting hematopoietic toxicity. Autologous HCT is commonly used to treat intermediate- and high-grade non-Hodgkin lymphoma (NHL), MM, relapsed or refractory Hodgkin lymphoma, and rarely autoimmune disorders such as scleroderma.[4] Patients do not benefit from an immunologic GVT effect while undergoing an autologous transplant; instead, the administration of high-dose chemotherapy followed by an autologous stem-cell transplant in chemotherapy-sensitive malignancies relies on the high-dose preparative regimen alone to eradicate the malignant disease. Autologous HCT circumvents the need for histocompatible donors, does not risk GVHD, and is associated with a lower transplant-related mortality rate.[4] However, since many malignancies are derived from stem cells or early progenitor cells, this approach is limited to certain malignancies as there is the potential of removing malignant cells during apheresis and transplanting those back into the patient.

Allogeneic HCT involves the transplantation of HSCs obtained from a different person’s (donor) BM, peripheral blood stem cells (PBSCs), or UCB to the recipient (also called the host). The type of donor, as described in Table 98–2, is distinguished by whether or not they are a relative to the recipient and by the shared number of common immunologic cell surface HLAs.[6,7]

HLAs are encoded by a group of genes on the short arm of chromosome 6, called the major histocompatibility complex (MHC). These are proteins expressed on cell surfaces that have a critical role in alloimmunity.[6] A set of HLA gene alleles, or haplotype, is inherited from each parent. HLA compatibility with the donor is usually defined by high-resolution typing for 10 alleles: HLA-A, HLA-B, HLA-C, HLA-DR, and HLA-DQ.[6] A 10 out of 10 match would be all of the alleles match, while a 9/9 would means there was 1 allele mismatch, an 8/8 would be 2 allele mismatch, etc. Recently there has been evidence that DPB1 matching may be of value as well and may be included in typing.[8]

KEY CONCEPT The transplanted donor HSCs are immunologically active, and thus, there is potential for bidirectional graft rejection. When host-versus-graft reactions occur, cytotoxic T cells and natural killer (NK) cells belonging to the host (recipient) recognize HLA antigens of the graft (donor HSCs) as foreign, and this can lead to a rejection of the transplanted cells in which case there would be a failed engraftment.[9] To prevent this complication, part of the preparative regimen is always targeted toward the recipient’s immune system and recipients are given immune suppression. The immune suppression is also to prevent GVHD, in which the immunologically active cells in the graft recognize host HLA antigens as foreign and elicit an immune response against them.[10]

Graft-versus-Host Disease Pathophysiology

One of the most important principles in the pathophysiology of allogeneic HCT is the understanding of GVHD and HLA

Table 98–2

Classification of Allogeneic Transplants

Type of Donor	HLA 8/8 Match or greater	Less than HLA 8/8 Match
Sibling	Matched related donor (MRD)	Haploidentical (Haplo)
Parent or child		Haploidentical
Unrelated	Matched unrelated donor (MUD)	Mismatched unrelated donor (MMUD)
Umbilical cord blood	Matched UCB	Mismatched UCB (MMUCB)
Identical twin	Syngeneic	

histocompatibility. Histocompatibility differences in HLA-A, HLA-B, HLA-C, HLA-DR, and HLA-DQ between the donor and the recipient are the primary risk for GVHD. The degree of HLA mismatching is associated with the risk of acute GVHD, graft rejection, and mortality.[11] An HLA identical sibling donor is generally considered the best donor for allogeneic HCT; however, less than 30% of patients have a matched sibling.[9] For URDs, 10/10 matches are the best; however, matching at the HLA-A, HLA-B, HLA-C, and HLA-DRB1 loci (an 8/8 HLA match) is comparable.

GVHD involves a complex network of inflammation and cellular interactions of both innate and adaptive immunity. Three sequential phases have been described including activation of antigen presenting cells (APCs), donor T-cell activation, proliferation, differentiation, migration, and finally target tissue destruction.[11-14] Understanding these phases and the molecular processes is essential for understanding potential drug targets and therapies for GVHD. The GVHD pathophysiology is summarized in Figure 98–1.

▶ *Phase 1: Activation of Antigen Presenting Cells (APCs)*

In the first phase, host APCs (eg, dendritic cells, macrophages) are activated. The end result is increased cytokine activation including TNFα, interleukin (IL)-6, IL-2, and IL-1, and chemokines such as CCL2-5 and CXCL9-11.

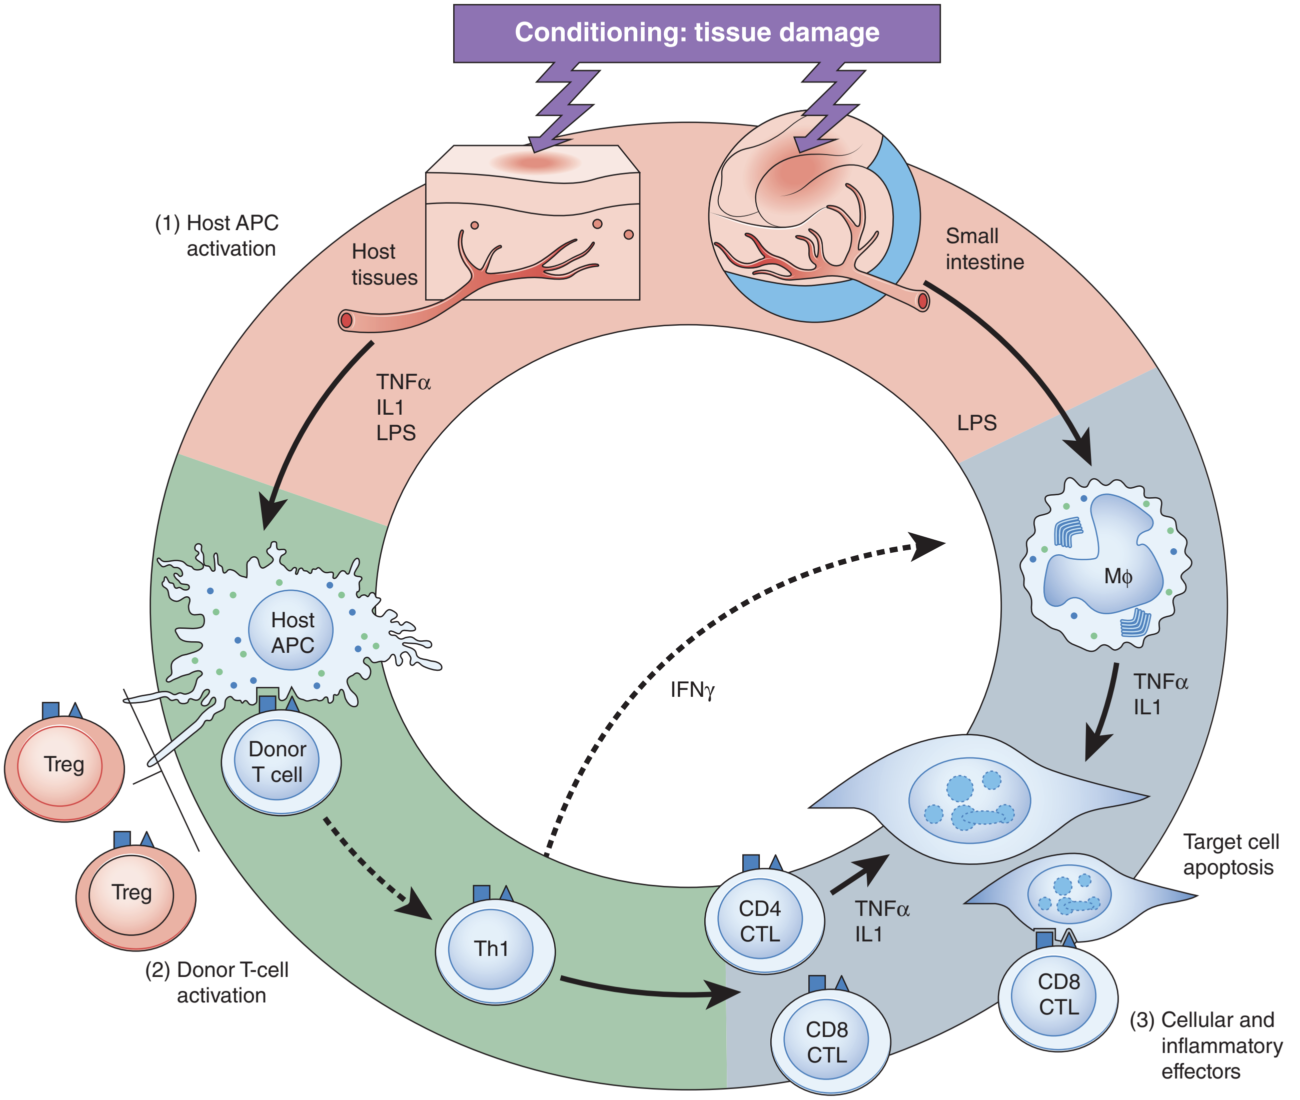

FIGURE 98–1. Pathophysiology of acute graft-versus-host disease. During the first phase (1), recipient conditioning regimen damages patient tissues and causes release of inflammatory cytokines such as TNF-α, IL-1, and IL-7, which leads to activation of host APCs. In the second phase (2), host APCs activate mature donor cells through IL-12 and IL-23 to produce T helper cell type 1 (Th1) cytokines, such as IL-2, IL-6, and IFN-γ. The synthesis of inflammatory cytokines is partly inhibited by IL-10. Activated Th1 cells induce increased indoleamine 2,3-dioxygenase (IDO) secretion from host APCs through IFN-γ secretion, thus stimulating immunotolerizing Tregs. IFN-γ also stimulates mononuclear cells to secrete inflammatory cytokines, such as IL-1 and TNF-α. (3) Th1 cells promote proliferation and differentiation of activated cytotoxic T lymphocytes (CTLs) and stimulate natural killer (NK) cells, which, in turn, induce apoptosis. Lipopolysaccharide (LPS) and bacterial cell wall components that have leaked through the damaged intestinal mucosa stimulate mononuclear cells through interactions with NOD2 and other innate immunity proteins, thus triggering additional inflammatory cytokine production causing apoptosis. Patient Encounter Part 1

A 65-year-old African American male is diagnosed with FLT3+ acute myeloid leukemia who smoked until 20 years ago and has diabetes controlled with oral medications. The patient achieved partial remission with induction chemotherapy and complete remission on reinduction. He is now being evaluated for stem-cell transplant. He has one sibling who is 79 years old and a 6/10 (4/6) match. He has two children that underwent HLA typing: a 35-year-old son is a 7/10 (4/6) HLA match and a 42-year-old daughter, with three children, who is an 8/10 (4/6) match. A search from the national registry, the closest match is a female with 8/10 (4/6).

What type of transplant would be best for this patient (autologous or allogeneic)?

Does the choice of transplant depend on the HLA results?

Which of these donors would be the best selection for this patient?

Can allogeneic transplants use a patient's child as a donor?

▸ Phase 2: Donor T-Cell Activation, Expansion, and Trafficking

The donor T cells interact with the APCs from phase 1 causing T-cell activation, proliferation, and differentiation. While much emphasis has been placed on the CD8+ T cells, there may be several types of T cells involved including CD4+ T cells, Th1, Th2, Th17, T follicular helper (Tfh), and the GVHD suppressing regulatory T cells (Tregs). This is all controlled by cytokines secreted by the activated T cells. These cytokines are classified as Th1 (IFN-γ, IL-2, and TNFα) or Th2 (IL-4, IL-5, IL-10, and IL-13) and Th17 (IL-17). The cascade of Th1 cytokines clearly can induce GVHD; however, the balance of Th1 and Th2 cytokines is important as well. During this phase, T cells also start to move from the lymphoid system to target tissues through chemokine signaling such as CCL2, CCL3, CCL4, CCL5 and CXCL9, CXCL10, and CXCL11 and then bind by adhesion molecules like integrins. This process can explain why certain organs are specifically targeted for GVHD and may provide specific therapy. For example, the T cells are driven to the gastrointestinal (GI) tract by α4β7 integrin which could be inhibited by vedolizumab.

▸ Phase 3: Cellular and Inflammatory Effector Phase

This phase is where the cytokines developed earlier amplify the cellular and inflammatory mediators causing T cells, neutrophils, macrophages, NK cells, and NK-T cells to damage tissues and organs.[14]

In this phase, there still continues to be secretion of many inflammatory cytokines especially TNFα which can also drive effector cells to target organs and directly cause tissue damage via apoptosis, which is generally reported on pathology review of biopsies; however, necrosis may also be present.

PHARMACOLOGIC THERAPY AND HCT TREATMENT PROCESS

The HCT process contains several steps as outlined in Figures 98–2 and 98–3 including HSC collection, preparative or conditioning chemotherapy, HSC infusion, engraftment period, early post engraftment and acute GVHD period (allogeneic HCT), late post engraftment and chronic GVHD period (allogeneic HCT), and long-term outcome period which each involve specific therapies and potential complications.

Hematopoietic Stem Cells: Sources and Collection

KEY CONCEPT There are three main sources for HSCs: BM, peripheral blood (PBSCs), and UCB.[1] Harvesting HSCs directly from the BM requires a surgical procedure and with the development of the hematopoietic growth factor (HGF), granulocyte colony-stimulating factor (filgrastim, Neupogen), has been largely replaced by PBSCs. Filgrastim is given daily for 5 to 7 days and causes mobilization of stem cells out of the marrow into the peripheral blood where they can be collected by apheresis making this a much safer and simpler procedure.[1] The goal is to collect at least 2 to 3×10^6 CD34+ cells/kg of the recipient. PBSCs are almost always used for autologous HCT. Sometimes, however in an autologous recipient, it may be difficult to mobilize enough cells into the peripheral blood due to marrow suppression from prior therapy such as chemotherapy or lenalidomide. If this is the case the combination of chemotherapy (ie, cyclophosphamide or etoposide) with an HGF enhances PBPC mobilization relative to HGF alone.[15] In addition to treating the underlying malignancy, this approach lowers the risk of tumor cell contamination and the number of apheresis collections required, but there is a greater risk of thrombocytopenia, neutropenia, and hospitalization for neutropenic fever.[15] The HGF is initiated after completion of chemotherapy and is continued until apheresis is complete. To avoid mobilizing with chemotherapy, plerixafor (Mozobil) was FDA approved in combination with HGF to mobilize stem cells for autologous transplants in MM and NHL patients.[16] HSCs are attached to the BM stroma by the chemokine receptor CXCR4,

which is blocked by plerixafor, thus releasing cells into the peripheral blood for collection.

Cells for allogeneic HCT, except for UCB, are usually collected within 24 hours of the transplant and are given to the recipient without freezing. PBPCs are most commonly used for allogeneic HCT. The donor is given HGFs for 5 days, and then apheresis is used to collect the cells with the optimal number of CD34+ collected being 4 to 8 × 10^6 cells/kg of recipient body weight.[1] Allogeneic PBPC grafts contain approximately 10 times more T and B cells than BM grafts, and data has shown that allogeneic PBSCs may induce more chronic GVHD than cells from the BM, however, there was no difference in overall survival (OS), relapse, acute GVHD, or mortality at 2 years.[17] There has been an increasing trend, especially in related donors and pediatric transplants, to use BM cells.[4] The BM may need additional processing if the donor and recipient are ABO incompatible, which occurs in up to 30% of HCTs.[18] Red blood cells (RBCs) may need to be removed before infusion into the recipient to help prevent immune-mediated hemolytic anemia and thrombotic microangiopathic syndromes.

UCB offers an alternative stem-cell source to patients requiring an allogeneic transplant who do not have an acceptable matched related or URD.[7] The cord blood is obtained from a consenting donor in the delivery room after birth and delivery of the placenta. The UCB is processed, a sample is sent for HLA typing, and the cord blood is frozen and stored for future use. Numerous UCB registries exist, with the goal of providing alternative sources of allogeneic stem cells. UCB offers the advantage of being readily available, and has provided a stem-cell source to a more diverse patient population, in addition to a lower risk of GVHD.[19] Limitations include an increased risk of graft failure, delayed immune reconstitution leading to an increase in infections, and the inability to use donor-lymphocyte infusions in the event of relapse.[7] Cord blood has a limited number of CD34+ stem cells, thus limiting the size of the recipient so as to not risk failed engraftment. To overcome this and make this process even available in adults, the cells from two different umbilical cords can be given. While only one cord fully engrafts, the addition of the second cord significantly increases engraftment.[7]

▶ *T-Cell Depletion*

Immunocompetent T lymphocytes may be depleted from the donor BM *ex vivo* before infusion using physical (eg, density-gradient fractionation) and/or immunologic (eg, antithymocyte globulin [ATG] antibodies) methods.[20] It may also be done *in vivo* where ATG or alemtuzumab is given as part of the conditioning regimen to reduce the recipients T cells, but because of the long half-life of these antibodies, they can also deplete T cells that are infused with the transplant. This effect will be greater with higher doses of ATG or alemtuzumab and the closer to the transplant they are given.[21] T cell–depleted grafts decrease the risk of GVHD but also increase the risk of graft failure and of malignant disease relapse due to less GVT effects.[20] This may be a preferred option for nonmalignant transplants such as replacement of an immune dysfunction where there is no need for GVT effect. This process also will delay functional recovery of T cells in the recipient causing significantly increased risk of infections especially viral reactivation and of Epstein–Barr virus (EBV)–associated lymphoproliferative disorders. The use of donor lymphocyte infusion (DLI) in patients who relapse after receiving a T cell–depleted HCT is often required. DLI is a process where T-lymphocytes from the original stem-cell donor are infused after the transplant to augment an antitumor immune response or ensure that the donor stem cells remain engrafted, this can also increase the risk of developing GVHD. This clearly demonstrates the delicate balance between GVHD and GVT effects of T cells.

A newer version of T-cell depletion, developed with haploidentical HCT, is to give posttransplant cyclophosphamide at 50 mg/kg on days + 3 and + 4 after cell infusion and then calcineurin inhibitors and mycophenolate mofetil are started on day + 5.[22] The purpose of this is to allow the transplanted T cells to start to expand and possibly achieve tumor recognition and then destroy those alloreactive cells allowing immunologic tolerance and decreased GVHD. Stem cells should not be affected with cyclophosphamide due to low proliferation rate and the protection of high intracellular levels of aldehyde dehydrogenase. This approach has been shown to have overall comparable outcomes to matched related and matched unrelated transplants.[22]

Conditioning (or Preparative Regimen) for HCT

For both allogeneic and autologous transplants, HSCs are infused after the administration of chemotherapy and/or radiation, termed the conditioning or preparative regimen. There are two primary classifications of the preparative regimen. **KEY CONCEPT** A myeloablative preparative regimen involves the administration of chemotherapy which will cause full ablation to the recipient's BM. A nonmyeloablative preparative regimen utilizes a less intensive regimen to allow for better tolerability allowing older patients or those with some comorbidities to receive a transplant.[23] Other terminology often used is a "full intensity or reduced intensity" preparative regimen. Full intensity regimens are also usually myeloablative; however, reduced intensity may consist of a regimen that come close to being myeloablative but in some patients may not completely ablate the BM. Examples of commonly used preparative regimens are included in Table 98–3.

After an allogeneic HCT, it is possible to measure the percentage of donor cells versus the percentage of recipient CD3+ T cells and CD33+ myeloid cells in the blood and in the BM, which is called chimerism. After a myeloablative transplant, generally patients have 100% chimerism with all the cells being the donor. However, after a nonmyeloablative or reduced intensity transplant, it may take a few months before the donor fully engrafts and there will be a mixed chimerism (ie, donor 70% CD3+, and 50% CD33+, recipient 30% CD3+ and 50% CD33+) before this occurs. A mixed chimerism may also allow result in less early GVHD until more donor T cells take over, but here is also the risk of recipient taking over in which case DLI may be necessary.

▸ *Myeloablative Preparative Regimens*

Myeloablative conditioning refers to regimens of high-dose chemotherapy with or without radiation causing BM aplasia that would lead to death without stem-cell support. In both autologous and allogeneic HCT, infusion of stem cells circumvents this dose-limiting toxicity of myelosuppression, maximizing the potential value of the steep dose–response curve to alkylating agents and radiation, suppressing the host immune system, and creating space in the marrow compartment to facilitate engraftment. The preparative regimen is designed to eradicate immunologically active host tissues (lymphoid tissue and macrophages) and to prevent or minimize the development of host-versus-graft reactions. Most allogeneic preparative regimens for the treatment of hematologic malignancies contain cyclophosphamide, radiation, or both. The combination of cyclophosphamide and total-body irradiation (TBI) was one of the first preparative regimens developed and is still used widely today. Both cyclophosphamide and TBI are immunosuppressive and have inherent activity against hematologic malignancies (eg, leukemias and lymphomas), but hematopoietic stem cells are resistant to cyclophosphamide. TBI has the added advantage of being devoid of active metabolites that might interfere with the activity of donor hematopoietic cells. In addition, TBI eradicates residual malignant cells at sanctuary sites such as the central nervous system. Modifications of the cyclophosphamide–TBI preparative regimen include replacing TBI with other agents that are active against hematopoietic stem cells

Table 98–3

Commonly Used Preparative Regimens for HCT

Type of HCT	Preparative Regimen	Dose and Schedule for Adults
Allogeneic	Myeloablative CY-TBI	CY 60 mg/kg/day IV on 2 consecutive days before TBI 10–16 Gy fractionated over 1–7 days (varies)
Allogeneic, autologous	Myeloablative BU-CY	Busulfan 1 mg/kg per dose PO or 0.8 mg/kg per dose IV every 6 hours × 16 doses CY 60 mg/kg/day IV daily × 2 days after BU
Allogeneic	Myeloablative FLU-BU4[a]	Busulfan 3.6mg/kg IV daily × 4 days Fludarabine 40 mg/m^2 IV daily × 4 days
Autologous	Myeloablative BEAM (carmustine/ etoposide/-cytarabine/ melphalan)	Carmustine 300 mg/m^2 IV Etoposide 400–800 mg/m^2 IV given over 4 days Cytarabine 400–1600 mg/m^2 IV given over 4 days Melphalan 140 mg/m^2 IV
Allogeneic	Reduced intensity FLU-MEL	Fludarabine 25–30 mg/m^2 IV daily × 4–5 days Melphalan 100–180 mg/m^2 IV daily × 1 day
Allogeneic	Nonmyeloablative FLU-BU2	Busulfan 3.6 mg/kg IV daily × 2 days Fludarabine 40 mg/m^2 IV daily × 4 days
Allogeneic	Nonmyeloablative FLU-TBI	Fludarabine 25–30 mg/m^2/day IV daily × 3 days TBI 2 Gy × one dose

[a] Regimen may be considered myeloablative or reduced intensity dependent on busulfan AUC target.

BEAM, carmustine, etoposide, cytarabine, and melphalan; BU-CY, busulfan and cyclophosphamide; BU-FLU, busulfan and fludarabine; CY-TBI, cyclophosphamide–total-body irradiation; FLU-MEL, fludarabine and melphalan; IV, intravenous; PO, oral; TBI, total-body irradiation.

Data from Gyurkocza B, Sandeaier BM. Conditioning regimens for hematopoietic cell transplantation: one size does not fit all. Blood. 2014;124:344–353.

(eg, busulfan) or adding other chemotherapeutic or monoclonal agents to the existing regimen in hopes of minimizing long-term toxicities. In the case of a mismatched allogeneic HCT with a substantially increased chance of graft rejection, ATG also may be added to the preparative regimen to further immunosuppress the recipient through T-cell depletion.

The optimal myeloablative preparative regimen remains elusive as no clinical trial has definitively shown superiority of one regimen. Busulfan–cyclophosphamide (BU-CY) is a chemotherapy-only option used to avoid the toxicities associated with TBI. Furthermore, busulfan combined with the purine analog fludarabine (FLU-BU4) has even fewer toxicities compared to BU-CY with similar outcomes. Busulfan is an alkylating agent with activity in numerous hematologic malignancies. Intravenous busulfan with pharmacokinetic monitoring may improve outcomes when utilized with BU-CY and FLU-BU compared to CY-TBI in AML patients, although preparative regimens should be tailored to the primary disease and to the degree of HLA compatibility.[21]

At most HCT centers, age younger than 70 years and good renal, hepatic, pulmonary, and cardiac function as well as performance status are considered eligibility requirements for myeloablative allogeneic HCT.

▶ *Reduced Intensity and Nonmyeloablative Preparative Regimens*

A reduced intensity preparative regimen is composed of less toxic agents, lower doses of chemotherapy, and radiation, in the hope of being able to offer the benefit of an allogeneic HCT to more patients with less toxicity. In these cases, it is still critical to make sure the recipient's immune system is suppressed to hinder graft rejection, so these regimens often include fludarabine, a potent agent against T cells, or may include immune therapies such as ATG or alemtuzumab in the preparative regimen to assure host T-cell depletion; however, this comes with increased risk of infections and possibly higher relapse rates, especially if higher doses of ATG are used.[21] These regimens rely on the concept of a GVT effect as more residual disease remains due to the less intense conditioning.

Due to the severe regimen-related toxicity of a myeloablative preparative regimen, the use of HCT traditionally was limited to younger patients with minimal comorbidities. Most patients diagnosed with cancer are elderly; therefore, myeloablative HCT could not be offered to a substantial portion of cancer patients. The concept of donor immune response having a GVT effect gave rise to the theory of a strongly immunosuppressive, but not completely myeloablative, preparative regimen Reduced intensity is an intermediate category of reduced dose chemotherapy that may be considered myeloablative or nonmyeloablative, yet still require stem-cell rescue. Fludarabine, a purine analog, is commonly used due to potent immunosuppressive effects in combination with lower dose alkylating agents (eg, busulfan-half dose, melphalan) or TBI.

The nonmyeloablative preparative regimen does not completely eliminate host normal and malignant cells. Donor cells eradicate residual host hematopoiesis, and the GVT effects generally occur after the development of full donor T-cell chimerism. Thus, although transplant-related mortality is decreased due to reduced toxicity, there are higher rates of relapse.

▶ *Toxicities and Management of Preparative Regimens*

Myelosuppression is a frequent dose-limiting toxicity for antineoplastics when administered in the conventional doses used to treat cancer. However, because myelosuppression is circumvented with hematopoietic rescue in the case of patients receiving HCT, the dose-limiting toxicities of these myeloablative preparative regimens are nonhematologic and vary with the preparative regimen used. Most patients undergoing HCT experience toxicities commonly associated with chemotherapy (eg, alopecia, mucositis, nausea and vomiting, and infertility), albeit these toxicities are magnified in the HCT population.

Busulfan Seizures Seizures have been reported in both adult and pediatric patients receiving high-dose busulfan for HCT preparative regimens. Anticonvulsants are used to minimize the risk of seizures. Anticonvulsants are begun shortly before busulfan, with the loading dose, if necessary, completed at least 6 hours before the first busulfan dose. Phenytoin was the standard for many years and is the most studied. Oral loading and maintenance regimens generally are sufficient because target phenytoin concentrations of 10 to 20 mcg/mL (10–20 mg/L; 40–79 μmol/L) can be achieved by the peak time of seizure risk at 48 to 72 hours. Due to drug interactions and adverse effects, alternatives to phenytoin such as benzodiazepines or levetiracetam are preferred and have similar efficacy.[24] Antiseizure medications usually are discontinued 24 to 48 hours after administration of the last dose of busulfan. Seizures still can occur despite the use of prophylactic anticonvulsants and usually do not result in permanent neurologic deficits.

▶ *Adaptive Dosing of Busulfan*

The considerable interpatient variability in the pharmacokinetics of both oral and IV busulfan along with the identified concentration–effect relationships has led to the pharmacokinetic monitoring and adaptive dosing of busulfan.[25] Adjusting the busulfan dose to achieve a target concentration or exposure minimizes the toxicities of the BU-CY regimen, particularly hepatic sinusoidal obstruction syndrome (SOS; formerly referred to as veno-occlusive disease [VOD]) while improving engraftment and relapse rates.[25] Most transplant centers have adopted this practice and have internal therapeutic drug monitoring guidelines to adjust for a specified concentration at steady state or area under the curve.

HSC INFUSION (DAY 0)

Day 0 is designated as the day of infusion of the HSCs, this is often an emotional and celebratory day for patients and their families and is often deemed as a secondary birthday. The cells are given as an intravenous infusion and will track to the BM. If

Patient Encounter Part 2

The patient agrees to haploidentical transplant with PRPCs from his 35-year-old son who is a 7/10 (4/6) HLA match. The patient has blood type O and the son has type A. The preparative regimen is fludarabine and cyclophosphamide.

How is a haploidentical transplant different from a matched related sibling or a matched unrelated donor?

What nonhematologic toxicities are associated with the preparative regimen?

What type of preparative regimen is this patient receiving? How does this differ from other types of preparative regimens?

the cells were cryopreserved, they are thawed at the bedside and infused immediately. The DMSO in the cryopreserved product may cause nausea, emesis, or infusion-related reactions primarily from histamine release. Premedications of an antihistamine, an antiemetic, acetaminophen, and possibly a corticosteroid are common. Rarely DMSO can cause hypotension, neurologic symptoms, respiratory symptoms such as bronchospasm or an anaphylactic type reaction.[26] It is recommended that the maximum dose of DMSO delivered is 1 mL/kg/day, occasionally a patient may need to split the dose and receive the cells over 2 days. DMSO is partially cleared renally and fluids are given for hydration. DMSO is also cleared through the lungs and expired out into the air. This results in a pungent smell similar to garlic or creamed corn for 24 to 48 hours. Patients are given mints to block some of the bitter flavor the DMSO may cause as well as prevent nausea and vomiting.

For an allogeneic HCT it is important that immune suppression for prophylaxis of GVHD should be therapeutic before the cells are infused as this decreases severe GVHD incidence. Also if there is an ABO mismatch there is a risk of hemolysis with infusion. Prehydration, acetaminophen, antihistamine, and a steroid are common with ABO mismatch cell infusions. If there is a major ABO incompatibility the recipient may also receive plasma pheresis to remove antibodies before the cells are infused. Rituximab may be given to inhibit recipient B cells and decrease further antibody production before the donor cells engraft.[18]

Immune Suppression for Prevention of Acute GVHD in Allogeneic HCT

KEY CONCEPT Acute GVHD is a leading cause of morbidity and mortality after allogeneic HCT occurring in approximately 35% to 47% of patients, and thus, efforts have focused on utilizing immune suppression to prevent GVHD.[4] The donor graft and preparative regimen influence the prophylactic regimen for acute GVHD, with two primary approaches being most common. One approach involves T-cell depletion as discussed earlier and the second approach is to suppress T-cell function and expansion using a two-drug immunosuppressive therapy that typically consists of a calcineurin inhibitor (ie, cyclosporine or tacrolimus) with either low dose methotrexate on days + 1, + 3, + 6, and + 11 after myeloablative HCT or with mycophenolate mofetil for 28 days after a nonmyeloablative HCT.[1]

Since the calcineurin inhibitors (ie, cyclosporine and tacrolimus) inhibit both cytotoxic and helper T-cell proliferation and activation through inhibition of IL-2, they should be initiated 2 to 3 days before and have therapeutic levels before donor cell infusion. Studies comparing cyclosporine and tacrolimus in combination with methotrexate have shown that tacrolimus administration is associated with a lower incidence of grade II to IV acute GVHD and a similar incidence of chronic GVHD but variable effects on OS.

A newer version of T-cell depletion, developed with haploidentical HCT, is to give posttransplant cyclophosphamide at 50 mg/kg on days + 3 and + 4 after cell infusion and then calcineurin inhibitors and mycophenolate mofetil are started on day + 5.[22] The purpose of this is to allow the transplanted T cells to start to expand and possibly achieve tumor recognition and then destroy those alloreactive cells allowing immunologic tolerance and decreased GVHD. Stem cells should not be affected with cyclophosphamide due to low proliferation rate and the protection of high intracellular levels of aldehyde dehydrogenase. This approach has been shown to have overall comparable outcomes to matched related and matched unrelated transplants.[22]

Patient Encounter Part 3

It is transplant day (day 0) and the patient has several family members come for his "new birthday" celebration. The son has just finished the cell collection, and there were 5.5×10^6 cells per kg of the patient collected. The patient is excited to receive his new cells. The patient has blood type O and the son has type A.

Do the cells need to be processed before giving to the patient?

How are the cells given to the patient?

Will there be DMSO in the cells?

What type of prophylactic medications are given before the cells?

When will this patient's calcineurin inhibitor start and why? What monitoring parameters are necessary for this medication to ensure safety and efficacy?

Will this patient receive methotrexate or mycophenolate mofetil with the calcineurin inhibitor?

Will this patient receive any chemotherapy after the transplant, why?

▸ *Adaptive Dosing of the Calcineurin Inhibitors*

KEY CONCEPT The calcineurin inhibitors cyclosporine and tacrolimus are pharmacokinetically monitored and adjusted to target therapeutic concentration ranges. Cyclosporine and tacrolimus trough concentrations are associated with acute GVHD and nephrotoxicity. Cyclosporine trough concentrations usually are maintained between 150 and 400 ng/mL (125 and 333 nmol/L) in patients undergoing allogeneic HCT depending on the assay utilized with TDX having higher levels than HPLC.[27] Tacrolimus trough concentrations are often targeted to a range of 5 to 15 ng/mL (6.2–18.6 nmol/L).[28,29] Nephrotoxicity can occur despite low or normal concentrations of the calcineurin inhibitor and may be a consequence of other drug- or disease-related factors known to influence the development of nephrotoxicity (eg, genetic risk factors, concurrent use of other nephrotoxic agents, and sepsis). Careful monitoring for drug interactions via CYP 3A4 and P-glycoprotein is essential. The calcineurin inhibitor doses are adjusted based on serum drug levels and the calculated creatinine clearance. Common adverse effects to these agents include neurotoxicity, hypertension, hyperkalemia, hypomagnesemia, and/or nephrotoxicity (which may lead to an impaired clearance of methotrexate).

ENGRAFTMENT PERIOD (DAY + 1 TO DAY + 30)

This is one of the most acute times in the transplant process as the side effects from the conditioning regimen occur and patients are generally treated in the hospital for much of this time. The conditioning therapy will cause pancytopenia and the initial outcome desired from the HCT is to have the infused cells return to the BM and start to proliferate and mature and return to appropriate peripheral counts of neutrophils, erythrocytes and platelets. Engraftment is defined as the point at which the patient maintains a sustainable absolute neutrophil count (ANC) of greater than 500 cells/mm^3 (0.5×10^9/L) and a sustained platelet count of 20,000/mm^3 (20×10^9/L) lasting 3 or more consecutive days without transfusions. The median time to engraftment of neutrophils is approximately 10 to 16 days and engraftment of neutrophils is often the requirement for hospital discharge. Several factors may affect the timing including the source and quantity of stem cells, HGF use, infection, and engraftment syndrome. PBPCs tend to have the most rapid engraftment followed closely by BM; however, UCB tends to be the slowest, often taking 20 to 30 days. HGFs are recommended to hasten hematopoietic recovery during the period of aplasia after an autologous, haploidentical and UCB transplant starting between days 5 and 7 after transplant and continuing until ANC greater than 1000 to 2000 cells/mm^3 ($1–2 \times 10^9$/L) × 2 days.[30] It is controversial whether or not HGFs should be administered after allogeneic transplant as use may increase GVHD and mortality; however, they are used routinely at many centers.[31]

Chemotherapy-Induced Gastrointestinal Effects

The preparative regimen causes damage to the rapidly dividing epithelial cells lining the GI tract resulting in inflammation, apoptosis, and possible ulceration. Higher intensity myeloablative regimens are at especially high risk for severe GI toxicity, specifically mucositis or stomatitis that can happen throughout the entire GI system, this causes diarrhea as well as nausea and vomiting. Patients may also have delayed chemotherapy-induced nausea and vomiting (CINV) during this time. Prevention and treatment of CINV should be addressed accordingly as per published clinical practice guidelines and are further detailed in Chapter 99.[32] Olanzapine 5 to 10 mg daily has been shown to be effective both on the acute phase and the more delayed phase associated with transplant and should be considered for use until engraftment.[33]

Diarrhea occurs in the majority of patients beginning within the first week after the initiation of chemotherapy and/or radiation and may cause dehydration and severe electrolyte impairments, which should be monitored daily. During this early period, infections with *Clostridium difficile* are also common and must be evaluated before the administration of antidiarrheals. The breakdown in mucosal lining also allows for transit of bacteria and fungi from the GI tract, increasing the risk for infection.

Virtually all patients receiving a myeloablative preparative regimen experience oral mucositis resulting in severe pain and difficulty eating and swallowing. Routine oral care protocols are indicated to reduce the severity of mucositis, which may occur within the first week of HCT and persist for approximately 2 weeks.[34] Palifermin, a keratinocyte growth factor, may be considered for patients undergoing autologous HCT with myeloablative TBI-based preparative regimens. Patients may require parenteral opioid analgesics for pain relief owing to mucositis, and total parenteral nutrition may be necessary to prevent the development of nutritional deficiencies.

▶ *Infections and Neutropenic Fever*

KEY CONCEPT Fever and infection in these neutropenic patients are common and patients receive prophylaxis with broad spectrum antibiotics (ie, levofloxacin), antivirals (ie, acyclovir, letermovir), and antifungals (ie, fluconazole, echinocandins, or broad-spectrum azoles) at this early stage. Orders for blood and urine cultures and intravenous therapy with antibacterials covering pseudomonas and GI organisms should be readily available for activation when a fever over 38°C occurs.

▶ *Sinusoidal Obstruction Syndrome*

Hepatic SOS is a life-threatening complication that may occur secondary to preparative regimens or radiation. The pathogenesis of SOS is not completely understood but the key event appears to be sinusoidal endothelial damage caused by the preparative regimen which initiates the coagulation cascade, induces thrombosis of the hepatic venules, and eventually leads to fibrous obliteration of the affected venules.[35]

The clinical manifestations of SOS are hyperbilirubinemia, jaundice, fluid retention, weight gain, and right upper quadrant abdominal pain. To make a clinical diagnosis of SOS, these features must occur in the absence of other causes of posttransplant liver failure, including GVHD, viral hepatitis, fungal abscesses, or drug reactions. Most cases of SOS occur within 3 weeks of HCT, and the clinical diagnosis can be confirmed histologically via liver biopsy.

Patients with mild SOS have an excellent prognosis, but those with more severe disease (ie, bilirubin higher than 20 mg/dL [342 μmol/L] or weight gain greater than 15%) with renal impairment (SCr greater than 3 × baseline, GFR less than 40% baseline and/or oxygen saturation less than 90% on room air) have a high mortality rate. Pretransplant risk factors for SOS include a mismatched or unrelated graft, increased age, prior abdominal radiation or stem-cell transplant, exposure to inotuzumab or gemtuzumab ozogamicin, and increased transaminases before HCT.[35] Interpatient variability in the metabolism and clearance of the chemotherapy (ie, BU-CY) used within the preparative regimen also may be associated with a poor outcome, although the relationships vary within the various preparative regimens. The association of SOS with busulfan concentrations is discussed in the section on adaptive dosing of busulfan. Use of ursodiol, has been associated with a lower incidence of SOS in a limited number of small, randomized studies and may be recommended for SOS prophylaxis.[35]

The mainstay of treatment for established SOS is supportive care aimed at sodium restriction, increasing intravascular volume, decreasing extracellular fluid accumulation, and minimizing factors that contribute to or exacerbate hepatotoxicity and encephalopathy. Defibrotide, an oligonucleotide with antithrombotic, antiischemic, and anti-inflammatory activity, is FDA approved for the treatment of SOS in patients with renal or pulmonary dysfunction following HCT. In a phase III clinical trial, defibrotide improved day + 100 OS from 25% to 38.2% compared to placebo and was generally well tolerated.[35] Defibrotide has been evaluated for SOS prophylaxis with mixed results.

▶ *Engraftment Syndrome*

Around the time of neutrophil engraftment, a cytokine release may lead to a “Cytokine Storm or Engraftment Syndrome” characterized by fever, skin rash, and weight gain and may involve diarrhea, pulmonary edema, liver and renal dysfunction and encephalopathy. In allogeneic transplant this appears to be an early phase GVHD which increases the risk of later onset severe GVHD and mortality.[36] Engraftment syndrome can be severe and may lead to mortality if not recognized early and aggressive treatment with prednisone or methylprednisolone 1 to 2 mg/kg/day may be required with a taper after symptoms resolve.

▶ *Idiopathic Pulmonary Syndrome (IPS)*

Idiopathic pulmonary syndrome (IPS) is used to define a spectrum of noninfectious, diffuse lung injuries that include multilobar airspace opacities on chest imaging, absence of lower respiratory tract infection, and hypoxemia that occur following allogeneic HCT with most cases occurring in the first month.[37] The mortality rate is approximately 50% to 70%.[37] Risk factors include conditioning intensity, TBI dose, high-grade acute GVHD and advanced age; however, TBI more than 12 Gy may be the most important. Lung shielding is recommended when delivering high-dose TBI. Viral reactivation, including HHV6 which occurs commonly in the first 30 days, may confound the diagnosis or it may increase the risk of IPS.[37] Standard therapy has been methylprednisolone 2 mg/kg/day. TNF and IL-6 have been shown to be high in both serum and BAL fluid and TNF inhibition or IL-6 inhibition and addition of etanercept to methylprednisolone has been studied in pediatrics.[38]

▶ *Hemorrhagic Cystitis*

High-dose cyclophosphamide causes moderate to severe hemorrhagic cystitis; acrolein, a metabolite of cyclophosphamide, is the putative bladder toxin. Preventive measures to lower the risk of hemorrhagic cystitis include vigorous hydration, continuous bladder irrigation, or concomitant use of the uroprotectant 2-mercaptoethane sulfonate (mesna). The American Society of Clinical Oncology (ASCO) Guidelines for the Use of Chemotherapy and Radiotherapy Protectants recommends the use of mesna plus saline diuresis or forced saline diuresis to lower the incidence of urothelial toxicity with high-dose cyclophosphamide in the setting of HCT.[39] Hemorrhagic cystitis may also be caused by BK or adenovirus post HCT which should be evaluated by polymerase chain reaction copy number. These infections are treated with decreased immune suppression if possible and cidofovir which may cause significant renal toxicity that can be limited by using a low dose cidofovir.[40] Patients must be well hydrated and calcineurin inhibitor levels monitored carefully.

▶ *Graft Failure*

Graft failure is defined as the lack of functional hematopoiesis after HCT and can occur initially as a primary failure where initial hematopoietic recovery fails to take place or can occur later after 30 days as a secondary failure often in association with recurrence of the disease or reappearance of host cells after initial donor cell engraftment.[9] A delicate balance between host and donor effector cells in the BM is necessary to ensure adequate engraftment because residual host-versus-graft effects may lead to graft rejection. The incidence of graft rejection is higher in patients with aplastic anemia and those with HLA mismatched or T-cell–depleted marrow.[9] Graft rejection is uncommon in patients with leukemia receiving myeloablative preparative regimens with a histocompatible allogeneic donor.

Therapeutic options for the treatment of graft rejection or graft failure are limited and may include addition of sargramostim or use of thrombopoietin agonist (especially for poor platelet engraftment), which also stimulates stem cells.[41] A second HCT is the most definitive therapy, although the associated complications and toxicities may preclude its use.[42]

Patient Encounter Part 4

The patient starts to have some anxiety shortly after the transplant. He develops nausea and vomiting on day + 4, he becomes neutropenic on day + 5, and on day + 8, he starts granulocyte colony stimulating factor injections daily. He develops neutropenic fever and significant diarrhea on day + 9. On day + 15, his neutrophils are 0.5×10^9 cells/L, and he starts to have fever, rash, increased diarrheas, and shortness of breath requiring 4 L of oxygen. On day + 18, he engrafts with an absolute neutrophil count of 4.8×10^9 cells/L.

What antiemetic may be particularly helpful for this patient?

Are there risks to giving growth factor to this patient?

What infectious complications are of a concern for this patient during the early transplant period?

What work up should be done for his initial diarrhea?

What is likely causing his symptoms starting on day + 15 and how would you treat this?

EARLY POST ENGRAFTMENT PERIOD (DAY + 30 TO DAY + 100)

Acute Graft-Versus-Host Disease

While acute GVHD may happen before day + 30 or after day + 100 the most common occurrence is between this time period. **KEY CONCEPT** GVHD is caused by the activation of donor lymphocytes, leading to alloreactive immune damage to potentially any part of the recipient's body; however, it presents most commonly in the skin, GI system, and liver. Immune-mediated destruction of tissues, a hallmark of GVHD, disrupts the integrity of protective mucosal barriers and, thus, provides an environment that favors the establishment of opportunistic infections as discussed in the Infectious disease section. The combination of GVHD and infectious complications are leading causes of mortality for allogeneic HCT patients. GVHD is divided into acute and chronic categories based on clinical manifestations. Traditionally, the boundary between acute and chronic GVHD was set at 100 days after HCT; however, National Institute of Health (NIH) consensus criteria has refined the definition of both acute and chronic GVHD based on clinical symptoms and organs involved rather than the time of onset and also describe an overlap syndrome where there is a mix of acute and chronic GVHD symptoms.[43]

Acute GVHD is defined as classic aGVHD symptoms (erythema, maculopapular rash, nausea, vomiting, anorexia, profuse diarrhea, ileus, or cholestatic liver disease) occurring within 100 days after transplantation or after DLI in a patient not meeting criteria for the diagnosis of chronic GVHD. Persistent, recurrent, or late onset acute GVHD is defined as features of classic acute GVHD occurring beyond 100 days post transplantation or after DLI in a patient not meeting criteria for the diagnosis of chronic GVHD (often seen during the taper or withdrawal of immune suppression). The term "overlap" refers to the presence of one or more acute GVHD manifestations in a patient with a diagnosis of chronic GVHD and can be present at initial diagnosis of chronic GVHD or can develop after the diagnosis of chronic GVHD and may recur with or without resolution of prior chronic GVHD manifestations.

Skin is the most affected organ with an erythematous, maculopapular rash. In severe cases the skin may blister and ulcerate and may lose many layers of skin, similar care to burn victims may be required. GI acute GVHD is often difficult to treat and may present as nausea, vomiting, anorexia, diarrhea, and/or abdominal pain. It may involve any or all of the intestine and/or stomach. Lower GI aGVHD generally results in secretory diarrhea which can be several liters a day and may cause significant bleeding because of mucosal ulceration. Liver acute GVHD is often difficult to distinguish from possible other causes, such as drug-related toxicities or viral infections, and often is assumed if other organs have GVHD but may only be confirmed with a liver biopsy. Generally, an increase in liver function enzymes and/or bilirubin are the initial signs followed by jaundice.

A few staging systems exist that are based on clinical criteria is used to grade acute GVHD. The severity of organ involvement is staged on an ordinal scale from 0 (no symptoms) to 4 (severe symptoms), and then an overall grade of 0 to IV is established

Table 98–4

Mount Sinai Acute GVHD International Consortium (MAGIC) Staging of Acute GVHD[44]

			GI/Gut (Stool Output per Day)	
Stage	**Skin**	**Liver (Bilirubin)**	**Adult**	**Child**
0	No GVHD rash	< 2 mg/dL	< 500 mL or < 3 episodes/day	< 10 mL/kg or < 4 episodes/day
1	Maculopapular rash < 25% BSA	2–3 mg/dL	500–999 mL or 3–4 episodes/day	10–19.9 mL/kg or 4–6 episodes/day; persistent nausea, vomiting, or anorexia, with a positive result from upper GI biopsy
2	Maculopapular rash 25%–50% BSA	3.1–6 mg/dL	1000–1500 mL or 5–7 episodes/day	20–30 mL/kg or 7–10 episodes/day
3	Maculopapular rash > 50% BSA	6.1–15 mg/dL	> 1500 mL or > 7 episodes/day	> 30 mL/kg or > 10 episodes/day
4	Generalized erythroderma plus bullous formation and desquamation > 5% BSA	> 15 mg/dL	Severe abdominal pain with or without ileus, or grossly bloody stool (regardless of stool volume)	Severe abdominal pain with or without ileus, or grossly bloody stool (regardless of stool volume)

From Harris AC, Young R, Devine S, et al. International, multicenter standardization of acute graft-versus-host disease clinical data collection: a report from the Mount Sinai Acute GVHD International Consortium. Biol Blood Marrow Transplant/ 2016;224–10.

based on the number and extent of involved organs as shown in Table 98–4 and Table 98-5. However, Upper GI GVHD is only classified as stage 0 if no or intermittent nausea, vomiting or anorexia or stage 1 if persistent nausea, vomiting or anorexia.[44]

▸ *Treatment of Acute GVHD*

First-Line Therapy of Acute GVHD For most grade II to IV aGVHD or any visceral involvement initial treatment is methylprednisolone 2 mg/kg/day or equivalent steroid and a calcineurin inhibitor.[14] Corticosteroids have several mechanisms including indirectly halting the progression of immune-mediated destruction of host tissues by blocking macrophage-derived IL-1 secretion. IL-1 is a primary stimulus for T helper cell–induced secretion of IL-2, which, in turn, is responsible for stimulating proliferation of cytotoxic T lymphocytes.

In certain cases with limited low grade acute GVHD, like grade I skin GVHD, systemic steroids can be initially spared with the use of topical steroids alone. For only upper GI GVHD, which is usually more responsive to steroids, methylprednisolone 1 mg/kg/day can be effective and oral budesonide solution may be added. Despite high-dose steroids being the standard for over 25 years, responses are poor with only 40% to 50% of grade II to IV achieving a complete or partial response.[14] To try and improve first-line response, a randomized phase III trial added mycophenolate mofetil to steroids and a CI as initial therapy without benefit compared to steroids and CI alone; thus, steroids remain first-line therapy.[45] Since the response to initial therapy correlates directly with posttransplant survival it is imperative to find more effective therapy first-line therapy and it is especially critical to have effective second-line therapy.

Table 98–5

Overall Clinical Grade (Based Upon Most Severe Target Organ Involvement)[44]

Grade 0	No stage 1–4 of any organ
Grade I	Stage 1–2 skin without liver, upper GI, or lower GI involvement
Grade II	Stage 3 rash and/or stage 1 liver and/or stage 1 upper GI and/or stage 1 lower GI
Grade III	Stage 2–3 liver and/or stage 2–3 lower GI, with stage 0–3 skin and/or stage 0–1 upper GI
Grade IV	Stage 4 skin, liver or lower GI involvement, with stage 0–1 upper GI

In patients who do respond to corticosteroids, tapering should begin as soon as there is major improvement in the GVHD. Rapid tapers may increase the risk of GVHD exacerbation or recurrence while slow taper rates increase the risk of steroid-related complications including hypertension, hyperglycemia, edema, bone loss, muscular atrophy, cataracts and infections, especially fungal and viral. Generally, the dose is reduced by approximately 10% to 20% every 3 to 7 days depending on response and slowed when the prednisone dose is less than 30 mg/day.[46] Unfortunately recurrence or exacerbation of GVHD occurs approximately 35% to 50% of the time during steroid taper.

▸ *Second-Line Therapy of Acute GVHD*

There is only one FDA approved agent for second-line treatment of steroid refractory aGVHD, ruxolitinib. Ruxolitinib inhibits the Janus kinase 1 and 2 (JAK1/JAK2) tyrosine kinase resulting in the inhibition of several cytokines including TNF, IL-2, IL-6, and IFN-γ which utilize the JAK-STAT pathway for activation of cellular activity, thus blocking their critical roles in GVHD.[14] Ruxolitinib also impairs differentiation of $CD4^+$ T cells into IFN-γ- and IL-17A-producing cells, thus decreasing activity of GVHD while it increases regulatory T cells which are important in immunologic tolerance. The approval in patients 12 years of age and older was based on a prospective, open-label, single-cohort, multicenter study of ruxolitinib in 71 patients with grades II to IV SR aGVHD.[47]

▸ *Other Agents for Treatment of Steroid Refractory GVHD*

Tocilizumab IL-6 baseline and posttransplant levels are predictive of increased grade II to IV GVHD and OS.[50] Tocilizumab, the humanized anti-IL-6 receptor monoclonal antibody has been evaluated in small trials and has demonstrated a 63% complete response with GI GVHD as second line; however, another reported an ORR of 44% that was not durable in grade III to IV GVHD when used as third or fourth-line therapy.[51]

Anti-TNFα Agents One of the earliest targeted biologic therapies for GVHD were TNFα inhibitors and most reports are with infliximab, the chimeric monoclonal antibody which binds to either membrane bound or unbound TNFα, or etanercept, the soluble dimeric TNFα receptor 2 that only effects unbound TNFα. Infliximab has more inhibition of macrophages and is associated with higher rates of fungal infections, especially aspergillus. It is critical that with many of these biologic therapies appropriate antifungal prophylaxis is a standard part of the regimen.

While inhibition of TNFα is a common therapeutic strategy, the data are not convincing that this is a highly effective therapy in grade II to IV GVHD and may have higher responses when used for GI GVHD.[52] In a phase III randomized trial of high-dose corticosteroids with or without infliximab including 63 newly diagnosed GVHD patients, no statistically significant difference was found in GVHD-related mortality, nonrelapse mortality, or OS.

Anti-IL-2 Receptor Antibodies Basiliximab, a monoclonal antibody that inhibits IL-2 receptor has been evaluated in a few small studies and is used off-label for chronic graft versus host disease.

Sirolimus Sirolimus, a mammalian-target-of-rapamycin (mTOR) inhibitor, has an advantage of having no inhibitory effect on Treg cells, thus potentially helping to increase tolerance. The majority of studies for GVHD have combined sirolimus with steroids and a calcineurin inhibitor which will decrease Tregs, taking away one of the advantages of sirolimus.[52] Toxicities make sirolimus often difficult to use in patients with GVHD, especially with steroids. While hyperlipidemia and hypertriglyceridemia are very common effects, it is thrombotic microangiopathy that is generally most concerning and may be easily overlooked until severe. A case of severe life threatening hypertriglyceridemia with the combination of sirolimus and ruxolitinib has been reported.[53] There is also concern of longer term cardiac issues in these patients and potentially the increased cholesterol could lead to worsening of GVHD.[54] In addition, the risk of inflammatory pulmonary toxicity is worrisome especially if the patient has any active lung GVHD.

Alemtuzumab Alemtuzumab is a humanized monoclonal antibody to CD52 which is expressed on B cells, T cells, NK cells and dendritic cells causing extreme lymphopenia. While it would be expected that this should resolve active GVHD, the results tend to show about 50% to 60% overall response, however with an extremely high infection risk and mortality.[52] This demonstrates the delicate balance of immunosuppression that makes treating GVHD so difficult. While alemtuzumab does have efficacy it is important that mortality appears to increase significantly due to infection and these patients should have broad spectrum prophylaxis with a strong consideration for letermovir in patients at risk for cytomegalovirus (CMV). A risk adapted approach using lower doses needs to be further studied to determine if this would be a more feasible strategy to limit toxicities.[55-58]

Antithymocyte Globulin (ATG) Multiple retrospective studies have shown some benefit of ATG in SR disease.[52] Historically ATG increases the risk of developing posttransplant lymphoproliferative disorder so EBV copy numbers should be monitored routinely in patients receiving this therapy.

Mesenchymal Stem Cells Remestemcel-L is a frozen and cryopreserved allogeneic cell product that comprises *ex vivo* cultured adult human mesenchymal stromal cells (MSCs) from healthy adult donors. While still investigational it is very promising in steroid refractory aGVHD with 70% ORR and 70% Day 180 survival. MSCs are a rare population of multi potent nonhematopoietic progenitor cells that express low levels of MHC class I and an absence of the MHC class II molecule, HLA-DR, thus making these cells a hypo-immunogeneic phenotype.[48] MSCs are stimulated by TNFα binding to TNFR1 receptors on the MSCs and cause release of paracrine factors, such as PGE2, which then change naïve and effector T cells, dendritic cells, and NK cells toward anti-inflammatory phenotypes, also resulting in decreased secretion of proinflammatory cytokines, and increased regulatory T cells.[49]

GI Specific Therapies for GVHD Gastrointestinal GVHD occurs in up to 60% of transplants and may cause anorexia, malnutrition, severe diarrhea and GI bleeding. It is often steroid refractory and grade III to IV GVHD may cause mortality in over 70% of patients.[14] Oral budesonide (Entocort), approved for use in Crohn disease, is enteric coated, dissolving at high pH allowing delivery to the intestines. Budesonide is available in 3 mg capsules and is generally dosed as 3 mg daily to three times daily for GVHD. A newer product, budesonide extended release tablets (Uceris), is enteric coated and has delayed release beads potentially allowing for more drug to reach lower into the intestines and colon where GVHD may be more prevalent. It is only available in 9-mg capsules, so is generally dosed as 9 mg daily. While budesonide has not been evaluated in randomized trials, a similar agent, beclomethasone, has been assessed. A phase III trial compared immediate-release and sustained-release beclomethasone at 2 mg every 6 hours with prednisone to prednisone with improved response and mortality in the beclomethasone arm.[59] Beclomethasone also resulted in a faster prednisone taper. Budesonide plus beclomethasone has been shown to be effective also in upper GI GVHD.[60] While budesonide is often described as a "nonabsorbable" steroid it is actually greatly absorbed but undergoes extensive first pass metabolism primarily by CYP3A4 and thus has poor bioavailability. If patients are on an inhibitor of CYP3A4, such as voriconazole or posaconazole, the bioavailability will increase substantially, potentially to 100%. It is possible to monitor budesonide levels which may be important since it is a highly potent steroid.

Donor T lymphocytes which express α4β7 integrin will migrate to lymphoid tissues of the GI mucosa and this trafficking may be inhibited by blocking the α4β7 integrin with vedolizumab, a monoclonal antibody directed against α4β7 integrin. In a patient with only active GI GVHD, it would be ideal to specifically cause local immunosuppression, thus limiting potential complications of systemic suppression. Retrospective data from multiple centers evaluated the use of vedolizumab in steroid refractory acute GI GVHD patients with most having stages 2 to 4 disease.[61] A median of 3 weekly doses of 300 mg were given with 64% overall response at 6 to 10 weeks and OS 54% over 6 months. Several infections were still reported including eight nonserious infections and one serious infection with confirmed GI origin in eight patients. While larger trials would be beneficial, this is an intriguing therapy to help treat localized GI GVHD.

MAINTENANCE THERAPY AFTER TRANSPLANT

Relapse remains a primary cause of mortality after HCT. New strategies to use maintenance therapy after HCT have shown significant benefit in certain disease states.

Autologous HCT

After an autologous HCT, primary disease relapse is the most commonly reported cause of death, representing 37% of deaths in the first 100 days and 78% of deaths after 100 days. Autologous transplants for MM are not curative but are used to increase progression-free survival (PFS). Lenalidomide maintenance, generally with a dose of 10 mg daily, starting approximately day + 60 has become a standard for most patients.[62-64] A meta-analysis comparing lenalidomide to placebo demonstrate improved PFS but not survival with lenalidomide.[65] It should be noted that up to 27% of patients discontinued the drug due to adverse events and a small increase in secondary malignancies was reported in the lenalidomide group. It is often recommended that maintenance therapy continues until progressive disease as it appears that PFS after stopping therapy is approximately 10 months.[66] Other strategies in especially high-risk patients or patients refractory to lenalidomide have been to use proteasome inhibitors such as bortezomib.

Rituximab maintenance of 375 mg/m^2 every 2 months for 3 years after autologous HCT for mantle-cell lymphoma has demonstrated significantly better PFS than observation at 4 years.[67]

Allogeneic Transplants

Within the first 100 days, relapse of primary disease accounts for 34% of deaths in HLA-matched sibling transplant recipients and 51% of deaths in URD allogeneic HCT.[4] This is an especially vulnerable time for relapse due to immune suppression and especially high risk if there was any disease present before the transplant, including minimal residual disease, high-risk cytogenetics, or the use of reduced intensity conditioning therapy. Early, small trials have shown that giving maintenance therapy after allogeneic transplant appears to be beneficial in the setting of AML using targeted therapies for FLT3+ disease. A randomized phase II study comparing sorafenib, a raf tyrosine kinase inhibitor that has flt3 inhibition, to placebo demonstrated a 60% improvement in relapse-free survival (RFS), however no significant improvement in OS.[68] A second trial randomizing patients to the flt3 tyrosine kinase inhibitor midostaurin or standard of care demonstrated a 40% reduction in relapse risk and 42% reduction in death with midostaurin; however, these were not statistically significant.[69] Several questions remain with this approach including which is the most effective agent to use, if certain populations are best candidates and what is the optimal dose and duration of therapy. Another approach has been to use epigenetic modifiers such as DNA hypomethylating agents which have shown promising results but do have significant toxicity.[69] Prophylactic DLI, especially after a reduced intensity regimen, provides the rationale of increasing GVT effect.[70] A retrospective matched-pair analysis resulted in 69% improved 5-year RFS in high-risk AML, but no difference in standard risk AML; however, there was a trend toward more chronic GVHD. While many centers have readily adopted maintenance therapy in certain high-risk patients already, larger randomized trials are ongoing to better define the role of maintenance therapy including in the setting of minimal residual disease or not.

Patient Encounter Part 5

The patient was treated with methylprednisolone 2 mg/kg for 5 days and his engraftment syndrome resolved. He was then tapered to 1 mg/kg for another 5 days without any recurrence of symptoms, so he was discharged on 0.5 mg/kg for 3 days and 0.1 mg/kg for 3 days and stopped. On day + 45 he presents to the transplant clinic complaining of a skin rash covering 50% of his body surface including on her palms, arms, soles, and trunk. He also reports being persistently nauseous and having 5 to 6 stools throughout the day. He has an endoscopy and colonoscopy and a skin biopsy will all show areas of apoptotic cells representing GVHD. He is started back on methylprednisolone 2 mg/kg/day and in 5 days his skin is less red but is now on 70% of his body and his diarrhea is no better with 1.4 L output per day.

What grade of GVHD is did this patient present with?

Are steroids alone the appropriate option for first-line treatment?

How should this patient be monitored for progression of GVHD?

Is this patient steroid refractory?

What is approved for second-line therapy of GVHD?

Late Post Engraftment and Chronic GVHD Period (After Day + 100)

▶ *Taper of Immune Suppression*

Tapering schedules for the calcineurin inhibitors after myeloablative HCT vary widely. In patients without acute GVHD, the calcineurin inhibitor levels are maintained therapeutic for the first 3 months after HCT and then are tapered slowly with the intent of discontinuing all immunosuppressive agents by 6 to 9 months after HCT. By this time, immunologic tolerance may develop and patients may no longer require immunosuppressive therapy. There is a paucity of information regarding the optimal duration of GVHD prophylaxis after nonmyeloablative HCT and immunosuppression taper schedules may be individualized based on GVHD and disease-specific factors.[28] It is not uncommon that acute GVHD may occur or flare with the decreased immune suppression.

▶ *Chronic GVHD*

Chronic GVHD is a major cause of non-relapse mortality and morbidity in allogeneic HCT recipients with up to 40% of patients requiring systemic therapy within 2 years of HCT.[71] The clinical course of chronic GVHD is multifaceted, involving almost any organ in the body and symptoms resemble autoimmune and immunologic disorders (eg, scleroderma, sicca syndrome). Chronic GVHD symptoms usually present within 1 year after allogeneic HCT and often are preceded by acute GVHD, although up to 10% of cases present later.[71] A consensus document regarding the diagnosis and scoring of chronic GVHD has been published that proposes a clinical scoring system to describe chronic GVHD as opposed to historical descriptions of chronic GVHD, which described the phenomenon as being "limited" versus "extensive" in nature.[72] The diagnosis of chronic GVHD requires distinction from acute GVHD; the presence of at least one diagnostic clinical sign of chronic GVHD or presence of at least one distinctive manifestation confirmed by pertinent biopsy or other relevant tests; and exclusion of other possible diagnoses.

▶ *Prevention and Treatment of Chronic GVHD*

Chronic GVHD is not a continuation of acute GVHD, and separate approaches are needed for its prevention and management. Prevention of chronic GVHD through prolonged use of immunosuppressive medications has been unsuccessful.[12] Thus, its prevention is focused on minimization of factors associated with higher rates of chronic GVHD. Several recipient, donor, and transplant factors are relevant. Recipient risk factors that are not modifiable include older age, certain diagnoses (eg, chronic myeloid leukemia), and lack of an HLA-matched donor. Modifiable factors that may lower the risk of chronic GVHD include selection of a younger donor, avoidance of a multiparous female donor, use of UCB or BM grafts rather than PBPCs, and limitation of CD34+ and T-cell dose infused.[12] Development of acute GVHD is a major predictor for chronic GVHD, with 70% to 80% of those with grade II to IV acute GVHD developing chronic GVHD.[1]

Relative to no treatment, survival in those with chronic GVHD is improved by extended corticosteroid therapy; however, multiple long-term adverse effects are associated with corticosteroid use. The prednisone dosage is 1 mg/kg/day administered orally in divided doses for 30 days and then slowly converted to an alternate-day therapy. One to two months may pass before an improvement in clinical symptoms is noted, and therapy is usually continued for 9 to 12 months. Therapy can be tapered slowly after resolution of signs and symptoms of chronic GVHD. If a flare of chronic GVHD occurs during the tapering schedule or after therapy is discontinued, immunosuppressive therapy is restarted. Ibrutinib (Imbruvica), a Bruton tyrosine kinase (BTK) and IL-2–inducible T-cell kinase (ITK) inhibitor, has been approved for treatment of cGVHD after failure of at least one treatment option based on an open-label, multicenter, single-arm trial of 42 patients with cGVHD.[73] Dosed at 420 mg daily, ORR was 67% with 21% demonstrating a complete response. Adverse events including arrhythmias and myelosuppression resulted in approximately 30% of patients decreasing the dose and 30% stopping therapy. Other potential approaches for patients who are refractory to initial therapy include etanercept (Enbrel), infliximab (Remicade), mycophenolate mofetil (Cellcept), rituximab (Rituxan), extended use of calcineurin inhibitors, or extracorporeal photopheresis (ECP).[74] When immunosuppressive therapy is administered for long periods, the patient must be monitored closely for chronic toxicity. Cushingoid effects, osteoporosis, aseptic necrosis of the joints, and diabetes can develop with long-term corticosteroid use. Other severe complications include a high incidence of infection with encapsulated organisms and atypical pathogens such as *Pneumocystis jiroveci*, CMV, and varicella zoster virus (VZV).

► *Infectious Complications*

Recipients of HCT are at higher risk of bacterial, viral, and fungal infections and usually receive a prophylactic or preemptive regimen to minimize the morbidity and mortality associated with infectious complications. There are three periods of infectious risks, pre-engraftment (from 15 days prior and to 30 days after HCT), post-engraftment (engraftment to day 100 post-engraftment), and late (100 days after engraftment). From days 0 to 30 after HCT, particularly for patients undergoing myeloablative HCT, the primary pathogens are aerobic bacteria, *Candida* spp., and herpes simplex virus (HSV). Early infections are due to damage to the GI tract that results in translocation of gut microorganisms (Gram-negative, *Candida* spp., for example). Respiratory viruses such as respiratory syncytial virus (RSV), influenza, adenovirus, and parainfluenza virus are recognized increasingly as pathogens causing pneumonia, particularly during community outbreaks of infection with these organisms. Because of the need to administer chemotherapy, blood products, antibiotics, and other adjunctive medications, the placement of a semipermanent double- or triple-lumen central venous catheter is necessary before HCT. However, the indwelling IV central catheters put HCT recipients at increased risk for *Staphylococcus* infections.

The second period of infectious risk occurs after engraftment to post-transplant day 100. Bacterial infections are still of concern, but pathogens such as CMV, adenovirus, and *Aspergillus* spp. are common. A common manifestation of infection is interstitial pneumonitis (IP), which can be caused by CMV, adenovirus, *Aspergillus,* and *P. jiroveci*. Suppression of the immune system from acute GVHD and corticosteroids primarily targets T cells and contributes to the risk of such infections during this period.[75]

During the late period (100 days after engraftment), the predominant organisms are the encapsulated bacteria (eg, *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Neisseria meningitidis*), fungi, and VZV. The encapsulated organisms commonly cause sinopulmonary infections. The risk of infection during this late period is increased in patients with chronic GVHD as a result of prolonged immunosuppression.

Prevention and Treatment of Bacterial, Viral, and Fungal Infections Between the time of administration of the preparative regimen and successful engraftment, allogeneic myeloablative HCT patients undergo a period of pancytopenia that can last from 2 to 6 weeks. The risk of infection is reduced by aggressive use of antibacterial, antifungal, and antiviral therapy both prophylactically and for the treatment of documented infection. The antibacterial prophylactic regimens vary substantially among HCT centers. Some HCT centers use a prophylactic fluoroquinolone (eg, levofloxacin) on admission for HCT and then switch to a broad-spectrum IV antibiotic (eg, cefepime) when the patient experiences his or her first neutropenic fever. Although fluoroquinolones reduce the incidence of Gram-negative bacteremia, they have not been shown to affect mortality; the possibility of developing *Clostridium difficile*-associated diarrhea exists with fluoroquinolone use and infectious causes should be ruled out if diarrhea occurs. Concerns with fluoroquinolone use in the prophylactic setting during HCT include the emergence of resistant organisms and an increased risk for streptococcal infection. Broad-spectrum antipseudomonal IV antibiotics should be initiated immediately at the time of the first neutropenic fever under the treatment guidelines endorsed by the Infectious Disease Society of America for management of fever of unknown origin in the neutropenic host.[76]

Prevention of HSV and VZV Recipients who are HSV antibody seropositive before HCT are at high risk for reactivation of their HSV infection. Acyclovir is highly effective in preventing HSV reactivation, and thus, prophylactic acyclovir is standard in HSV-seropositive patients who are undergoing an allogeneic or autologous HCT. In the setting of HSV prophylaxis, dosing regimens for prophylactic acyclovir vary widely, from 400 mg twice daily to 800 mg three times daily.[77] Valacyclovir (Valtrex), a prodrug of acyclovir with improved bioavailability, may allow for adequate serum concentrations to prevent HSV in patients undergoing HCT as well.

In those with a history of VZV infection, VZV disease occurs in 30% of allogeneic HCT recipients.[77] The appropriate duration of VZV prophylaxis is controversial. Although VZV infections are reduced by prophylactic acyclovir administered from 1 to 2 months until 1 year after HCT, the risk of VZV persists in those on continued immunosuppression.[75]

Prevention and Preemptive Therapy of CMV Disease After allogeneic HCT, CMV disease is common and has high morbidity and mortality rates. Allogeneic patients are at greater risk than autologous recipients primarily because the latter more efficiently reconstitute their immune system after transplantation. Infection caused by CMV is usually asymptomatic and develops when CMV replication occurs. Replication occurs primarily in body fluids such as the blood (viremia), bronchoalveolar fluid, or urine (viruria). CMV disease occurs when the virus invades an organ or tissue. Pneumonia and gastroenteritis/colitis are the most common types of CMV disease after allogeneic HCT. The presence of a CMV viremia substantially increases the risk for developing invasive CMV disease. Strategies to prevent CMV infection have resulted in dramatic reductions in the incidence of CMV disease.

Primary CMV infection after transplant is rare and can be prevented with CMV seromatching, which includes transplanting PBPCs or BM from CMV-seronegative donors and infusing CMV-negative blood products to CMV-negative recipients. Antivirals are important in those who are CMV seropositive or have a CMV-seropositive graft, with three available approaches to minimize the morbidity associated with CMV. The first is universal prophylaxis, in which ganciclovir is begun at the time of engraftment and is continued until approximately day + 100; however, due to BM suppression, it is often difficult to start or to maintain appropriate doing. The second approach is preemptive therapy in which CMV titers in the blood by PCR are monitored weekly and therapy is started above a threshold level developed at the institution. The third approach utilizes the novel antiviral agent letermovir. By inhibiting the DNA terminase complex of CMV, letermovir selectively inhibits viral replication with minimal toxicity to human cells. A phase 3 placebo controlled study in CMV positive recipients utilizing letermovir 480 mg daily (or 240 mg if on cyclosporine) through week 14 after transplant demonstrated the incidence of clinically significant CMV infection, the primary endpoint, by week 24 was significantly reduced with letermovir.[78] However, all-cause mortality was significantly lower at week 24 in the letermovir group but not reduced at week 48.[79]

Fungal Infections

▶ *Prevention of Fungal Infections*

The widespread use of fluconazole prophylaxis since the early 1990s has led to a significant decline in the morbidity and mortality associated with invasive candidiasis in HCT recipients. However, invasive aspergillosis (IA), zygomycetes, and fluconazole-resistant *Candida* spp., such as *Candida krusei* and *Candida glabrata*, have increased markedly in incidence.[80] Itraconazole, another azole antifungal agent, has better *in vitro* activity against fluconazole-resistant fungi (eg, *Aspergillus* and some *Candida* spp.) and is more effective than fluconazole for long-term prophylaxis of invasive fungal infections after allogeneic HCT; however, itraconazole is used less often because of frequent GI side effects and concern for potential drug interactions. Posaconazole (Noxafil) is a triazole antifungal that has been approved by the FDA for prophylaxis in HCT patients with GVHD and is now the recommended prophylactic agent for this subset of HCT patients on immunosuppression.[80] Posaconazole oral suspension should be given with food to increase absorption but is still poorly absorbed in most patients and levels should be monitored to assure adequate absorption. The posaconazole extended release tablet can be administered without regard to food and has good bioavailability. Micafungin (Mycamine), an echinocandin, has been FDA approved for prophylaxis of *Candida* infections in patients undergoing HCT.

▶ *Risk Factors for Invasive Mold Infections*

Invasive mold infections (eg, *Aspergillus* spp., *Fusarium* spp., *Zygomycetes*, and *Scedosporium* spp.) are an increasing cause of morbidity and death after allogeneic and autologous HCT. It has been estimated that up to one-third of febrile neutropenic patients who do not respond to antibiotic therapy after 1 week are harboring a fungal infection. In HCT recipients, risk factors for invasive fungal infections include previous history of invasive infection; recipient factors, including older age, CMV seropositivity, and type of stem-cell transplant, treatment factors (eg, a fludarabine-based preparative regimen), transplant complications (eg, prolonged neutropenia, graft failure, and higher grade GVHD), and host factors (eg, diabetes, iron overload).[81] Infections with *Aspergillus* spp. remain the most common mold infections diagnosed in the HCT population and optimal treatment must be promptly initiated if indicated.

▶ *Treatment of Invasive Aspergillosis*

Early diagnosis and initiation of appropriate therapy may reduce the high mortality rate of IA. Outcomes also depend on recovery of the recipient's immune system and reduction of immunosuppression. Diagnosis is difficult with the use of computed tomography scans and cultures. Research is ongoing to evaluate the benefit of using nonculture-based methods, such as galactomannan and (1,3)-β-ᴅ-glucan antigen detection, which are components of the fungal cell wall that can be detected by commercially available assays.

Practice guidelines are available for the treatment of invasive *Aspergillus* infections in immunocompromised patients.[80] Available mold-active agents include triazole antifungals (itraconazole, voriconazole, posaconazole, and isavuconazole), echinocandins (caspofungin, micafungin, and anidulafungin), and amphotericin B formulations. The Infectious Disease Society of America Guidelines recommend early initiation of therapy with suspected infection. First-line therapy recommendation is voriconazole with alternatives being liposomal amphotericin or isavuconazole. Trough levels of the triazoles should be monitored at steady state. Many HCT patients are on prophylaxis with voriconazole, posaconazole, or isavuconazole, if aspergillosis occurs while on one of these agents then liposomal amphotericin would be recommended with careful monitoring of renal function and electrolytes. Also liposomal amphotericin plus an echinocandin could be considered.

The optimal duration of appropriate antifungal therapy for treating IA is individualized to the reconstitution of the patient's immune system and his or her response to antifungal treatment. Most clinicians continue aggressive antifungal therapy until the infection has stabilized radiographically and may continue with less aggressive "maintenance" therapy (eg, oral voriconazole) until immunosuppression is lessened or completed. In general, it is common to require several months of antifungal therapy to treat IA.

▶ *Pneumocystis Jiroveci*

After allogeneic HCT, prophylaxis for *P. jiroveci* (formerly *P. carinii*) pneumonia (PJP) is used because *Pneumocystis* is a serious infection with a high mortality rate if left untreated. Most centers use sulfamethoxazole/trimethoprim for 6 to 12 months after HCT; aerosolized or IV pentamidine, oral dapsone, and oral atovaquone are alternatives for patients who are allergic to sulfa drugs or who do not tolerate sulfamethoxazole/trimethoprim.[75] Because PJP most often occurs after engraftment, sulfamethoxazole/trimethoprim usually is begun after neutrophil recovery because of its myelosuppressive effects. Patients receiving prophylactic sulfamethoxazole/trimethoprim should be monitored closely for rash and unexplained neutropenia or thrombocytopenia. Autologous HCT patients do not receive posttransplant immunosuppression, and the risk of developing PJP is significantly lower; however, prophylaxis is still used often used for several months.

Patient Encounter Part 6

The patient was treated with methylprednisolone and ruxolitinib in conjunction with his tacrolimus which fully resolved his skin GVHD and significantly decreased his GI GVHD. He was requiring high doses of insulin, and he became so weak he had to use a wheelchair. Vedolizumab was added and after 3 weeks he also has resolution of his GI GVHD. He was then discharged from the hospital. On day + 130, he presented to clinic with extremely dry eyes and mouth and skin stiffening around his waist and arms where his acute GVHD was the worst. He also presented with progressive shortness of breath over the past 2 weeks, a CT was done revealing several nodules with a "halo" of ground glass attenuation, a bronchiolar lavage revealed aspergillus.

Is this patient experiencing chronic GVHD, what are his symptoms?

Are steroids alone the appropriate option for treatment?

How should his aspergillus be treated?

Should he be started on maintenance therapy for the AML?

Nonpharmacologic Therapy

▶ *Psychologic Support*

Patients and their caregivers may experience emotional and psychological distress during and for sometimes long after the HCT.[82] This may have negative impacts on recovery, increase GVHD, and even effect mortality. HCT may cause significant financial hardships, cause patients to move near a transplant center for a period of time, limit social contacts, and limit activities for a long period of time. Patients may experience long hospitalizations or GVHD with multiple readmissions and then face new long-term challenges with chronic GVHD. It is critical that patients are evaluated and monitored and behavioral therapies are implemented for both patients and caregivers to ease emotional burdens as much as possible through this process.

▶ *Graft-Versus-Tumor Effect*

A GVT effect caused by the donor lymphocytes occurs after transplant. This results in lower relapse rates in patients with GVHD relative to those who did not have GVHD; a higher rate of leukemia relapse after T-cell–depleted, autologous, or syngeneic HCT; and the effectiveness of DLIs in reinducing a remission in patients who relapsed after allogeneic HCT. Rapid taper of immunosuppression in patients with residual disease may induce a GVT effect. In DLI, lymphocytes are collected from the peripheral blood of the donor and administered to the recipient. Eradication of the recurrent malignancy is caused by either specific targeting of the tumor antigens or GVHD, which may affect cancer cells preferentially. Patients with hematologic malignancies (eg, CML and AML) and certain solid tumors (eg, renal cell carcinoma) appear to benefit from a GVT effect. These data gave rise to the use of nonmyeloablative preparative regimens.

LONG-TERM SURVIVORSHIP ISSUES AFTER HCT

The number of long-term HCT survivors is increasing as 5-year disease-free survival rates improve. HCT recipients—with either an autologous or an allogeneic graft—have a higher mortality rate than the general population.[5,83] **KEY CONCEPT** Long-term survivors of HCT should be monitored closely for many potential complications including cardiac, renal, hepatic, endocrine, and pulmonary toxicities as well as poor bone health, dental health, infections, and secondary malignancies.[5]

Survivors of HCT are at higher risk for secondary malignancies from the chemotherapy, TBI, immune suppression or from cytogenetic changes. Skin cancers are most prevalent and patients should assessed annually for new skin cancers. Long-term impairment of end-organ function of the kidneys, liver, and lungs, may be caused by the preparative regimen, infectious complications, posttransplant immunosuppression and/or from complications of GVHD. Many HCT recipients experience endocrine dysfunction, such as hypothyroidism from TBI, adrenal insufficiency from long-term corticosteroids to treat GVHD, thyroid dysfunction from GVHD, diabetes from GVHD and corticosteroids or TBI, and infertility from radiation and/or high doses of alkylating agents in myeloablative preparative regimens. Osteopenia has been found in more than half of HCT recipients, likely from gonadal dysfunction, corticosteroids, endocrine dysfunction, and vitamin deficiencies. Appropriate treatment and prevention, often with bisphosphonates, is important to help prevent fractures and osteoporosis.

Close monitoring of HCT recipients for infections is necessary because recovery of immune function is slow, sometimes requiring more than 2 years, even in the absence of immunosuppressants.[84] Fevers should be assessed and treated rapidly to minimize the likelihood of a fatal infection. HCT recipients—both autologous and allogeneic—lose memory B cells and thus lose the protective antibodies to vaccine-preventable diseases requiring reimmunization of HCT recipients.[85]

All survivors of HCT should be monitored routinely for signs of relapse. Allogeneic recipients must also always be monitored for chronic GVHD. They should be advised regarding revaccination and obtaining prompt medical care for fevers or signs of infection. Routine evaluations of organ function (ie, renal, hepatic, thyroid, and ovarian) and osteopenia/osteoporosis with bone density scans should occur and the appropriate management strategies initiated if necessary.

OUTCOME EVALUATION

The overall desired outcome with HCT is to cure the patient of his or her underlying disease while minimizing the short- and long-term morbidity associated with HCT. Early intense monitoring for nonhematologic toxicity of the preparative regimen during its administration and at least daily, with more frequent monitoring if the patient is experiencing these nonhematologic effects. Monitoring immune suppression and calcineurin levels are important for decreasing GVHD and nephrotoxicity. Monitoring for chimerism in allogeneic patients is important until full chimerism occurs. Patients should be assessed for infections throughout all phases of the transplant process. Monitoring for symptoms of GVHD are critical, especially to start therapy early in the process. Patients should be monitored for symptoms and signs of the disease that is being treated by HCT to assess the effectiveness of the HCT; for example, monitoring radiologic scans for lymphoma patients or appropriate biologic markers for myeloma patients. If a molecular target is present such as *BCR-ABL* positive ALL would be to monitor disease response by PCR of the *BCR-ABL* transcript. The actual clinical outcome monitored, along with the frequency of monitoring, is based on the underlying disease. If there is a targeted mutation and maintenance therapy was not given, then therapy should be considered with positive PCR.

Finally long-term monitoring of chronic GVHD symptoms and organ function and bone density is critical in providing successful outcomes.

Abbreviations Introduced in This Chapter

aGVHD	Acute graft-versus-host disease
AML	Acute myeloid leukemia
ANC	Absolute neutrophil count
ASCO	American Society of Clinical Oncology
ATG	Antithymocyte globulin
BMT	Bone marrow transplantation
BU-CY	Busulfan–cyclophosphamide
CD	Cluster of differentiation
CINV	Chemotherapy-induced nausea and vomiting
cGVHD	Chronic graft-versus-host disease
CML	Chronic myelogenous leukemia
CMV	Cytomegalovirus
CY-TBI	Cyclophosphamide–total-body irradiation
DMSO	Dimethyl sulfoxide
GVHD	Graft-versus-host disease
HGF	Hematopoietic growth factors
HLA	Human leukocyte antigen
HCT	Hematopoietic stem-cell transplant
IA	Invasive aspergillosis
IL	Interleukin
Mesna	2-mercaptoethane sulfonate sodium
MHC	Minor histocompatibility complex
MM	Multiple myeloma
NHL	Non-Hodgkin lymphoma
NK	Natural killer
NMDP	National Marrow Donor Program
PBPC	Peripheral blood progenitor cells
PJP	Pneumocystis pneumonia
SOS	Sinusoidal obstruction syndrome
SCr	Serum creatinine
TNF	Tumor Necrosis Factor
TBI	Total-body irradiation
UCB	Umbilical cord blood
VOD	Venoocclusive disease
VZV	Varicella zoster virus

Supportive Care in Oncology

Alexandre Chan and Lee Nguyen

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the impact of various supportive care interventions on the prognosis of patients with cancer.
2. Discuss the scientific basis for providing various supportive care interventions in the oncology patient population.
3. Identify patient-related and disease-related risk factors in defining a population for whom supportive care interventions would be of benefit.
4. Recognize typical presenting signs and symptoms of common complications and emergencies that require supportive care interventions.
5. Outline appropriate prevention and management strategies for various supportive care interventions.
6. Prepare a monitoring plan to evaluate the efficacy and toxicity of pharmacotherapy interventions for supportive care problems.

INTRODUCTION

Patients with cancer are at risk for serious adverse events that result from their treatment, the cancer, or both. The management of these complications is generally referred to as supportive care or symptom management. Examples of treatment-related complications include chemotherapy-induced nausea and vomiting (CINV), myelosuppression, febrile neutropenia (FN), hemorrhagic cystitis, mucositis, tumor lysis syndrome (TLS), and immunotherapy-related toxicities. Tumor or cancer-related complications include superior vena cava (SVC) obstruction, spinal cord compression, hypercalcemia, and brain metastases. In some cases, these events can be life threatening. SVC obstruction, spinal cord compression, TLS, and hypercalcemia have traditionally been defined as oncologic emergencies. Treatment- and disease-related complications in the cancer patients require rapid assessment and supportive care interventions. The onset of oncologic emergencies may herald the onset of an undiagnosed malignancy or progression or relapse of a preexisting malignancy. Optimal management of patients with various oncologic emergencies and complications requiring supportive care interventions can significantly decrease morbidity and mortality in patients with cancer. This chapter provides an overview of these issues.

CHEMOTHERAPY-INDUCED TOXICITIES: NAUSEA/VOMITING

Nausea and vomiting were once the most common feared toxicities by patients undergoing treatment. However, with the advent of supportive care, CINV is largely manageable with prophylactic usage of antiemetics.[1] KEY CONCEPT The optimal method of managing CINV is to provide adequate pharmacologic prophylaxis given a patient's risk level for emesis. Insufficient control during the first cycle of chemotherapy leads to more difficulty in controlling emesis for subsequent cycles.[2]

EPIDEMIOLOGY AND ETIOLOGY

Although it is widely known that chemotherapy causes nausea and vomiting, the rate of emesis varies depending on individual patient risk factors and drug therapy regimen. Therefore, cancer treatments are stratified into varying risk levels: high, moderate, low, and minimal. Agents with a "high" emetic risk cause emesis in more than 90% of cases if not given any prophylaxis. The rates of emesis for "moderate," "low," and "minimal" are 30% to 90%, 10% to 30%, and less than 10%, respectively. Table 99–1 lists the individual agents and their risk category.[3]

PATHOPHYSIOLOGY

The pathophysiology of nausea and vomiting is described in Chapter 20. Specific to CINV, the key receptors include serotonin (5-HT_3) receptors (located in the chemoreceptor trigger zone, emetic center of the medulla, and gastrointestinal [GI] tract) and neurokinin-1 (NK1) receptors (located in the emetic center of the medulla). Serotonin plays an important role in the genesis of acute vomiting, occurring within the first 24 hours of chemotherapy, because some cancer drug therapies can stimulate a release of serotonin from enterochromaffin cells in the GI tract. Serotonin then activates the emetic response by binding to $5HT_3$ receptors in the emetic center. This short-lived release of serotonin likely explains why serotonin antagonists are more beneficial for preventing acute versus delayed vomiting. Other sites that are targeted by antiemetics include dopamine, muscarinic (acetylcholine), histamine, and cannabinoid receptors.[1]

CLINICAL PRESENTATION AND DIAGNOSIS

CINV, although frequently discussed as one syndrome, includes two distinct clinical entities, including both nausea and vomiting. Nauseous patients may present with general GI upset and reflux and may report a sensation or desire to vomit

Table 99–1

Emetogenic Potential of Selected Chemotherapy

Risk	Agent
High emetic risk (> 90% of patients will vomit without appropriate antiemetics)	AC combination (doxorubicin or epirubicin and cyclophosphamide) Carmustine > 250 mg/m^2 Carboplatin AUC ≥ 4 Cisplatin Cyclophosphamide > 1500 mg/m^2 Dacarbazine Doxorubicin ≥ 60 mg/m^2 Epirubicin > 90 mg/m^2
Moderate emetic risk (30%–90%)	Amifostine > 300 mg/m^2 Arsenic trioxide Azacitidine Bendamustine Busulfan > 4 mg/m^2 Carboplatin AUC < 4 Carmustine ≤ 250 mg/m^2 Cyclophosphamide ≤ 1500 mg/m^2 Cytarabine > 200 mg/m^2 Daunorubicin Doxorubicin < 60 mg/m^2 Epirubicin < 90 mg/m^2 Idarubicin Ifosfamide < 2 g/m^2 Irinotecan Methotrexate > 250 mg/m^2 Oxaliplatin
Low emetic risk (10%–30%)	Ado-trastuzumab emtansine Afatinib (oral) Amifostine < 300 mg/m^2 Bexarotene Brentuximab Cabazitaxel Carfilzomib Capecitabine (oral) Dasatinib (oral) Docetaxel Doxorubicin (liposomal) Eribulin Erlotinib (oral) Etoposide 5-Fluorouracil Gemcitabine Ixabepilone Methotrexate > 50 mg/m^2 and < 250 mg/m^2 Mitomycin Mitoxantrone Paclitaxel Palbociclib (oral) Pemetrexed Sunitinib (oral) Topotecan Vorinostat
Minimal risk (< 10%)	Most other agents

Data from National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Antiemetic v.2.2020.

without being able to do so. In all cases, it is important that other etiologies of nausea and vomiting are ruled out before diagnosing chemotherapy as the cause. Other causes of nausea and vomiting may include bowel obstruction, opioid intolerance, electrolyte imbalances, brain metastases, and vestibular dysfunction.[4]

TREATMENT

Desired Outcomes

The desired outcome is to completely prevent or minimize the severity of nausea, vomiting, and the use of breakthrough antiemetic medications. In clinical trials, a common end point is "complete response," defined as having no emesis and no breakthrough medication use within a defined period of time.[5] If patients experience nausea or emesis, the goal is to quickly relieve the episode and prevent future nausea or vomiting, whether in the next few days or for the next cycle of chemotherapy.[4]

General Approach to Treatment

Treatment-related factors and patient-related factors can help define a patient population at risk for developing CINV.[2] Treatment-related factors include those chemotherapy agents with high and moderate levels of emetogenicity, dose, and schedule (see Table 99–1 for a complete listing).[3] CINV is typically a cyclical occurrence. Although this section focuses on CINV, it can be helpful for practitioners to remember that patients undergoing concomitant radiation therapy and chemotherapy are at risk for more severe nausea and vomiting. Radiation (particularly total-body irradiation as part of a conditioning regimen for stem-cell transplant) can cause a more cumulative (versus cyclical) nausea/vomiting phenomenon.[3]

Specific patient-related factors such as female gender, age less than 50, history of motion sickness, pregnancy-induced nausea or vomiting, anxiety, low alcohol consumption, and poor emetic control in previous chemotherapy cycles increase the risk of emesis.[6] It is important to design an antiemetic regimen with consideration of these patient-specific risk factors.[4] A well-designed regimen includes a prophylactic regimen targeting various phases of nausea/vomiting and a breakthrough antiemetic drug "as needed." Although many drugs are recommended as "breakthrough" drugs, choose a drug with a different mechanism of action compared with the drugs used for prophylaxis.[4]

▶ *Nonpharmacologic Therapy*

Nonpharmacologic therapies for nausea and vomiting can be useful adjuncts to drug therapy, particularly in the setting of anticipatory nausea and vomiting. Behavior therapies such as relaxation, guided imagery, and music therapy as well as acupuncture or acupressure may be useful in this setting. Mixed benefits have been observed with the use of ginger extract. Other general measures that can be taken include ensuring adequate sleep before treatment, eating smaller meals, and avoiding spicy and greasy foods and foods with strong odors.[4]

Clinical Presentation and Diagnosis of CINV

Acute Nausea/Vomiting

- Occurs within the first 24 hours after chemotherapy administration

Delayed Nausea/Vomiting

- Occurs between 24 hours and 5 days after chemotherapy administration

Anticipatory Nausea/Vomiting

- A learned, conditioned reflex response to a stimulus (sight, sound, smell) often associated with poor emetic control in a previous cycle of chemotherapy

Breakthrough Nausea/Vomiting

- Occurs despite prophylaxis with an appropriate antiemetic regimen

Differential Diagnosis

- Surgery, radiation
- Brain metastases
- Gastric outlet or bowel obstruction, constipation
- Hypercalcemia, hyperglycemia, hyponatremia, uremia
- Food poisoning or intolerance
- Other drugs (opioids)

Table 99–2

Recommended Therapy by Emetic Risk

Emetic Risk Category (Incidence of Emesis Without Antiemetics)	Antiemetic Regimens and Schedules
High: Cisplatin and other agents, (>90%)	5-HT_3 receptor antagonist: day 1[a] Dexamethasone: days 1–4 NK-1 receptor antagonist: day 1 only (except oral aprepitant: days 1–3) Olanzapine: days 1–4
High: Anthracycline combined with cyclophosphamide (>90%)	5-HT_3 receptor antagonist: day 1 Dexamethasone: day 1 NK-1 receptor antagonist: day 1 only (except oral aprepitant: days 1–3) Olanzapine: days 1–4
Moderate (30%–90%)	5-HT_3 receptor antagonist: day 1 Dexamethasone: day 1 *Or* 5-HT_3 receptor antagonist: day 1 Dexamethasone: days 1–3 for regimens with drugs known to cause delayed nausea/vomiting
Low (10%–30%)	Dexamethasone: day 1 *Or* 5-HT_3 receptor antagonist: day 1
Minimal (< 10%)	No routine prophylaxis. 5-HT3 receptor antagonists, others as needed

Data from Antiemetics, ASCO Guideline Update, 2020 and National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Antiemetics v.2.2020.

[a] If netupitant-palonosetron or fosnetupitant-palonosetron is used, no additional 5-HT3 receptor antagonist is needed.

▶ *Pharmacologic Therapy*

Nonprescription medications such as antacids, histamine-2 receptor blockers, and proton pump inhibitors can be helpful in reducing gastroesophageal reflux associated with some cancer treatments that may trigger or exacerbate CINV.[4] Nonprescription antihistamines marketed for nausea associated with motion sickness are not usually helpful in managing CINV.

Four drug classes are highly effective in preventing CINV: corticosteroids (dexamethasone), serotonin (5-HT3) receptor antagonists, NK1 receptor antagonists, and the thienobenzodiazepine, olanzapine.[3] Drugs with differing mechanisms of action are combined, depending on the emetic risk level of the chemotherapy regimen (Table 99–2).

Intravenous (IV) antiemetics are usually administered 30 minutes before chemotherapy, and oral antiemetics are administered 60 minutes before chemotherapy. Dexamethasone is the preferred agent to prevent CINV in the delayed setting (days 2–4 after chemotherapy administration) and given at dose of 8 mg once daily for 3 to 4 days.[3,4] The use of multiday dexamethasone should only be limited to highly emetogenic risk chemotherapy and only for those moderately emetogenic regimens known to cause delayed nausea and vomiting (such as cyclophosphamide, doxorubicin, and oxaliplatin) due to concerns for toxicities related to dexamethasone. In some cases, the serotonin antagonists may also be continued orally for 2 to 3 days after chemotherapy or be used in place of dexamethasone, though practice guidelines differ in their recommendations.[3,4] In view of the ability to decrease the persistence of CAR T-cell population, dexamethasone should be avoided for 3 to 5 days before and 90 days after CAR T-cell therapies. Several NK1 receptor antagonists are currently available, and these agents should be given on day 1 of the chemotherapy cycle, with the exception of oral aprepitant which should be continued on days 2 and 3 of the chemotherapy cycle. Netupitant and fosnetupitant are available as fixed combination products with palonosetron, which is a long-acting 5-HT$_3$ receptor.

Olanzapine is now a standard component of the antiemetic regimens for high emetic-risk chemotherapy at 10 mg by mouth once daily (5 mg by mouth once daily for elderly patients) for 4 days starting the day of chemotherapy and as an option to add to the antiemetic regimen for moderately emetogenic chemotherapy.[3,4] Olanzapine can be substituted for dexamethasone if patients are unable to tolerate dexamethasone (eg, diabetics).[4] Concerns of QT prolongation have resulted in the IV formulation of dolasetron to be removed from the market and dosing of ondansetron has been reduced to 16 mg IV as the 32 mg IV was reported to extend the QT interval.[7]

The other classes of antiemetics are usually prescribed “as needed” for breakthrough nausea or vomiting. The dopamine antagonists prochlorperazine and metoclopramide are usually recommended because they antagonize a different receptor than the drugs already given for prophylaxis. Other medications, including serotonin receptor antagonists, cannabinoids, dexamethasone, scopolamine, or olanzapine, may be used as alternatives to dopamine antagonists for breakthrough nausea and vomiting.[3,4] For those in any risk group who experience anticipatory nausea and vomiting, the addition of lorazepam for prophylaxis and breakthrough to behavioral therapy is recommended for its antiemetic and antianxiety properties, but not as a single-agent to prevent CINV.[3,4] Table 99–3 lists the doses of the antiemetic agents for prophylaxis and breakthrough use.

Table 99–3

Antiemetic Dosing

Antiemetic	Single Dose Administered Before Chemotherapy	Daily Schedule
5-HT$_3$ Receptor Antagonists		
Dolasetron	By mouth: 100 mg	100 mg by mouth daily
Granisetron	By mouth: 2 mg IV: 1 mg or 0.01 mg/kg Topical: 34.3-mg patch (apply 24–48 hours before chemotherapy, leave on for 7 days)	1–2 mg by mouth daily or 1 mg by mouth two times a day
Ondansetron	By mouth: 16–24 mg IV: 8–16 mg	8 mg by mouth two times a day or 16 mg by mouth daily
Palonosetron	IV: 0.25 mg	None
NK-1 Receptor Antagonists		
Aprepitant	By mouth: 125 mg IV emulsion: 130 mg	If oral on day 1, 80 mg by mouth days 2 and 3
Fosaprepitant	IV: 150 mg × 1	None
Netupitant/palonosetron combination	By mouth: netupitant 300 mg/palonosetron 0.5 mg IV: fosnetupitant 235 mg/palonosetron 0.25 mg	None
Rolapitant	By mouth: 180 mg	None
Others		
Dexamethasone	By mouth or IV: 12 mg	8 mg by mouth days 2–4
Olanzapine	5–10 mg by mouth daily	5–10 mg by mouth days 2–4

Data from Antiemetics, ASCO Guideline Update, 2020 and National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Antiemetics v.2.2020.

A prophylactic antiemetic regimen for high emetic risk levels of IV chemotherapy should be with a four-drug combination using dexamethasone, olanzapine, NK1 receptor antagonist, and 5-HT$_3$ antagonist to prevent both acute and delayed emesis.[3,4] Dexamethasone and olanzapine should be continued until day 4, and oral aprepitant is also administered on days 2 and 3 if oral aprepitant is used. In a phase 3 randomized trial, olanzapine versus placebo were added to aprepitant or fosaprepitant, a 5-HT$_3$ receptor antagonist and dexamethasone for patients receiving highly emetogenic chemotherapy. The four-drug combination with olanzapine substantially increased the response rate compared with placebo for acute, delayed, and overall control of CINV.[8] Currently, guidelines recommend the use of a four-drug combination as prophylactic antiemetics for high emetic risk chemotherapy regimens.

Patient Encounter 1: CINV

Your patient is receiving her second cycle of chemotherapy today. She had intractable nausea and vomiting after her last cycle of treatment. On interview with her pharmacist today, she is very anxious about her treatment, and she is experiencing severe nausea and retching symptoms.

What type of nausea is this patient manifesting?

What do you recommend for manage the nausea and vomiting in this patient?

For moderately emetogenic regimens, acute emesis is still of major concern, but the incidence of delayed emesis is less. Therefore, dexamethasone plus a 5-HT$_3$ antagonist should be given on day 1. On days 2 to 3, either the dexamethasone or the 5-HT$_3$ antagonist (dexamethasone preferred for regimens known to cause delayed CINV) is continued, though one exception is when palonosetron is given as the 5-HT$_3$ antagonist on day 1. Because its half-life is long, no redosing is necessary on subsequent days. While NK1 receptor antagonist is not routinely used for moderately emetogenic chemotherapy, if patients have clinical risk factors or if they experienced uncontrolled emesis with previous chemotherapy cycles, follow the suggest guidelines for "high" emetogenic risk level.[4]

For low emetic risk IV chemotherapy regimens, single-agent antiemetic prophylaxis with either dexamethasone or 5HT$_3$ antagonist is recommended 30 minutes before chemotherapy.[3,4] For minimal emetic risk groups, guidelines do not recommend routine prophylaxis with antiemetics; instead, patients should be provided with a drug to take as needed for nausea and vomiting.[3,4] Table 99–2 summarizes regimens for antiemetic prophylaxis for the different risk levels of IV chemotherapy.

Many oral anticancer agents are now available and are typically administered daily. For highly and moderately emetogenic oral anticancer therapy, an oral 5HT$_3$-antagonist is administered 60 minutes before each chemotherapy dose. For low–minimal risk oral anticancer agents, an "as needed" antiemetic agent may be given for any breakthrough nausea/vomiting.[4]

OUTCOME EVALUATION

Evaluating patients' nausea and vomiting when chemotherapy is given in the outpatient setting is challenging, as patients return home after drug administration and may or may not report inadequate control of nausea or emesis. Subsequent chemotherapy cycles may be poorly controlled, especially if patients do not state their experience with the previous cycle. To ameliorate this problem, patients' experiences with CINV should be assessed, particularly after the first and second cycles of chemotherapy. Patients should be asked about their previous emesis control with subsequent cycles of chemotherapy, and the prophylactic regimen may need to be adjusted. Patients should also be encouraged to self-report symptoms of nausea and vomiting while at home. Patients should be educated on appropriate usage of antiemetics at home, and side effects of the antiemetic regimen should be routinely assessed and reported.

MUCOSITIS

Mucositis is the inflammation of the mucosal lining in the oral cavity and GI tract caused by damage from radiation or cytotoxic chemotherapy, often leading to ulcers. Stomatitis is a related term that is specific to inflammation in the oral cavity and associated with mammalian target of rapamycin (mTOR) inhibitors, such as everolimus. Both mucositis and stomatitis are common supportive care issues that deserve attention and are associated with many negative health consequences, including pain, inadequate nutritional intake, and risk for infection. Diagnosis is based on symptoms of pain, vomiting, diarrhea, and impact on appetite, all of which are surrogates for the inflammation and damage to the mucosal lining due to the impractical nature of a definitive diagnosis by invasive endoscopic biopsy. Patients with mucositis often require parenteral analgesics, nutrition supplementation, and anti-infectives to treat concomitant bacterial, fungal, or viral infections. Furthermore, mucositis is associated with economic consequences, primarily increased length of hospital stay, nutrition support, pain management, and infection management. The use of evidence-based practice for prevention and treatment of mucositis can help improve patient outcomes.[9,10]

EPIDEMIOLOGY AND ETIOLOGY

The incidence of chemotherapy or radiation-induced mucositis depends mostly on the type of chemotherapy, the type and area of radiation, and the specific cancer. Studies have reported an incidence of about 85% in head and neck cancer patients receiving chemoradiation.[10] The World Health Organization estimates that approximately 75% of patients who are treated with high-dose chemotherapy for stem-cell transplantation developed oral mucositis.[10] Specific chemotherapy agents associated with moderate to severe mucositis include taxanes, anthracyclines, platinum analogues, methotrexate, and the fluoropyrimidines. Everolimus-associated stomatitis can appear within 8 weeks of initiating therapy.[11]

PATHOPHYSIOLOGY

The classical concept of mucositis pathophysiology asserts that direct cytotoxicity from chemotherapy or radiation to basal epithelial cells results in ulcerative lesions caused by a lack of regeneration. These lesions are further complicated by trauma or microorganism growth. However, the most recent theory of mucositis pathophysiology is more detailed and involves a multistage, dynamic process that builds upon the historical model.[9] According to this theory, there are five stages of mucositis: initiation, primary damage response, signal amplification, ulceration, and healing. It is important to note that these stages do not occur sequentially and may be influenced by both the oral and gut microbiome as well as genetic polymorphisms in individual patients. Prevention of mucositis or treatment in early stages results in the best outcomes for patients. mTOR inhibitors, on the other hand, cause injury to oral mucosa through the inflammatory cascade, causing loss of epithelial barrier function, impairing angiogenesis and vascular cell proliferation, and causing problems with wound healing.[12]

CLINICAL PRESENTATION AND DIAGNOSIS

Patients experiencing chemotherapy-induced mucositis may present along a continuum of mild, painless, erythematous ulcers to those that are painful and/or bleeding. Stomatitis associated with mTOR inhibitors are typically presented as discrete aphthous-like lesions, rather than diffuse inflammation, in the oral cavity. In both cases, patients will experience difficulty eating and swallowing or that may require treatment with hydration, antibiotics, and/or parenteral nutrition or opioid therapy in its most severe forms.[9,10]

Clinical Presentation and Diagnosis of Mucositis

- Chemotherapy-induced mucositis generally present with painful, erythematous ulcers develop on the lips, buccal mucosa, soft palate, floor of mouth, and throughout the entire gastrointestinal (GI) tract. Symptoms appear within 5 to 7 days after chemotherapy and resolve in 2 to 3 weeks.
- Oral lesions associated with mTOR inhibitors are typically shallow, nonconfluent ulcerations, well demarcated with intense erythematous margins, and involves nonkeratinized oral mucosa.
- Pain may affect ability to swallow and eat.
- The patient may have concomitant localized or systemic infection.
- Diarrhea is a symptom of mucositis in the lower GI tract; can lead to electrolyte imbalances.

TREATMENT

Nonpharmacologic Treatment

The goal of nonpharmacologic measures to prevent mucositis is to reduce the bacterial load. **KEY CONCEPT** A multiagent approach is important, with the fundamental approach to lessen the severity of mucositis begins with basic, good oral hygiene (brushing with a soft-bristled toothbrush at least twice daily, flossing, bland rinses, and saliva substitutes) and maintaining optimal nutritional support. Cryotherapy with ice chips is also helpful for patients at risk for mucositis who are receiving 5-FU–based chemotherapy or undergoing autologous stem-cell transplantation. Photobiomodulation, which includes low-level laser therapy, is helpful to prevent mucositis in the hematopoietic cell transplant (HCT) setting and patients with head and neck cancer receiving radiation with or without chemotherapy.[9]

Pharmacologic Treatment

In the setting of radiation therapy, amifostine, a free radical scavenger, at doses equal to or greater than 340 mg/m^2 intrarectal before each dose of radiation therapy for rectal cancer may be considered to prevent GI mucositis. Among all anti-inflammatory agents, benzydamine mouthwash is the only anti-inflammatory agent that is recommended for prevention of mucositis. Gelclair, Caphosol, and Biotene are gels that provide a protective barrier between damaged oral mucosa and the environment, lessening pain and irritation and are also sometimes used as part of the overall treatment of patients with mucositis. Other antimicrobial mouth washes and lozenges, sucralfate and chlorhexidine rinses, and "magic-mouthwash" compounded rinses are not generally recommended by clinical practice guidelines for mucositis prevention even though they are frequently used in practice. H_2-antagonists or omeprazole orally are recommended to prevent pain associated with mucositis and reflux following offending chemotherapy. Additionally, octreotide at a dose of at least 100 mcg subcutaneously twice daily is recommended to treat mucositis-related diarrhea associated with high-dose stem-cell transplantation if loperamide is ineffective. Probiotics containing *Lactobacillus* spp. may be beneficial for prevention of chemoradiotherapy- and radiotherapy-induced diarrhea in patients with pelvic malignancy.[9] Prophylactic use of a steroid containing mouth rinse (such as dexamethasone) can reduce the onset and severity of mTOR associated stomatitis.[11]

Unfortunately, little evidence is available to recommend specific treatments for mucositis. Pain assessment and appropriate management are important. Pain management may be achieved with oral or intravenous opioids, topical anesthetic products, and compounded rinses that incorporate lidocaine. In more severe cases in which infection of the oral mucosa is suspected, appropriate antimicrobial therapy is necessary to prevent systemic infection.[9,10]

Palifermin is FDA-approved for the prevention and treatment of mucositis in patients receiving high-dose chemotherapy as part of stem-cell transplant or induction regimens for leukemia. Palifermin is administered as an IV bolus injection at a dosage of 60 mcg/kg/day for 3 consecutive days before and 3 consecutive days after myelotoxic therapy for a total of six doses. Administering palifermin within 24 hours of chemotherapy can result in an increased sensitivity of rapidly dividing epithelial cells to the cytotoxic agent. For this reason, palifermin should not be administered for 24 hours before, 24 hours after, or during the infusion of myelotoxic chemotherapy to avoid increasing the severity and the duration of oral mucositis.[9,10]

OUTCOME EVALUATION

The goal of therapy is to prevent or decrease the severity and duration of mucositis. Outcomes measured in clinical trials often assess the incidence, duration, and severity of mucositis with a given intervention intended to prevent or treat mucositis. Agents that are intended to palliate the symptoms of mucositis are usually assessed by measures in pain scales and the ability to eat or drink.

HEMATOLOGIC COMPLICATIONS: FEBRILE NEUTROPENIA (FN)

INTRODUCTION

FN is a common adverse effect after administration of cytotoxic chemotherapy. The mortality rate in neutropenic patients caused by infectious complications can be as low as 2.8% but can exceed 50% mortality depending on resistant bacterial type, effective antimicrobial therapy, and patient comorbidities. Therefore, FN is considered a true oncologic emergency. Patients frequently require hospitalization for prompt administration of broad-spectrum antibiotics that are critical to avoid morbidity and mortality.

EPIDEMIOLOGY AND ETIOLOGY

The microorganisms responsible for infections in neutropenic patients have changed significantly in the last 50 years. From the 1960s through the mid-1980s, gram-negative organisms were the most common bacteria isolated. This pattern shifted to the gram-positive organisms in the late 1980s, which remain the most common isolates. Recent data indicate that incidence of gram-positive to gram-negative organisms isolated in bloodstream infections (BSI) in cancer patients were 60% to 40%.[13] The organism with highest prevalence was associated with skin pathogens, coagulase-negative staphylococci followed by the class of Enterbacteriales. The previous shift from gram-negative to gram-positive organism as the cause of BSIs were likely attributed to the widespread use of central venous catheters (CVC) and more aggressive chemotherapy regimens as well as the use of prophylactic antibiotics with relatively poor gram-positive coverage (quinolones). The decline in CVC used and reduced presence of severe mucositis may have contributed to the reduction of gram-positive organisms as a causative pathogen in BSIs.[14] Commonly isolated pathogens are shown in Table 99–4. Although gram-negative infections are less common, they cause the majority of infections in sites other than the blood and are particularly virulent.[15] It should be noted that isolates vary considerably among institutions; thus, attention to institutional isolation patterns is prudent.

Table 99–4

Commonly Isolated Pathogens in Patients with FN

Type of Organism	Comments
Bacteria	
Gram-positive organisms	Most common isolates in FN
Coagulase-negative *staphylococci* (ie, *Staphylococcus epidermidis*)	Between 70% and 90% resistant to methicillin; indolent course with low mortality
Staphylococcus aureus	Some centers report > 50% resistance to methicillin
Enterococcus spp.	Resistance to vancomycin ≥ 30%
Viridans streptococci	Increasing resistance to penicillin; result of fluoroquinolone prophylaxis; associated with mucositis
Gram-negative organisms	
Pseudomonas aeruginosa	Infections rapidly fatal
Escherichia coli	High mortality rate; increasing resistance to quinolones
Klebsiella spp.	Increased incidence of β-lactamase–producing strains
Enterobacter spp.	Increased incidence of β-lactamase–producing strains
Fungi	Occur primarily after prolonged neutropenia (> 1 week)
Yeasts	
Candida albicans	Increasing incidence (~10%); high mortality rate
Non-*albicans Candida* (*Candida krusei, Candida glabrata*)	Resistant to fluconazole; high mortality rate
Molds	Resistant to fluconazole; high mortality
Aspergillus spp.	Pulmonary infection common
Fusarium spp.	Emerging pathogen
Scedosporium spp.	Emerging pathogen

FN, febrile neutropenia.

Fungal infections caused by *Candida* spp. (especially *Candida albicans*) have emerged as significant pathogens, especially in patients with hematologic malignancies and those undergoing bone marrow transplantation (BMT). In addition, *Aspergillus* spp. are important pathogens in patients with prolonged and severe neutropenia.[15]

PATHOPHYSIOLOGY

The neutrophils are the primary defense mechanism against bacterial and fungal infection. Most infections in neutropenic patients are a result of organisms contained in endogenous flora, both on the skin and within the GI tract. These organisms are provided access to the bloodstream through

Patient Encounter 2: FN

A 66-year-old woman with HIV who received treatment for metastatic breast cancer presents today, 8 days after chemotherapy, for follow-up and laboratory check. Relevant laboratory study results include WBC count, 0.6 × 10^3/mL (0.6 × 10^9/L); HgB 9.0 g/dL (90 g/L; 5.59 mmol/L)); HCT 26.6% (0.266); PLT, 5 × 10^3/mL (5 × 10^9/L), CD4 count 250 cells/mm^3; serum chemistries within normal limits except; SCr, 1.3 mg/dL (115 μmol/L); and estimated GFR 44 mL/min/1.73m^2. Vitals: T 98.2°F (36.8°C); P 68 beats/min; RR 18 breaths/min; BP 110/74 mm Hg. The patient has no known drug allergies.

What risk factors for FN does this patient have?

How would you approach this patient?

breakdowns in host defense barriers (mucositis, use of central venous catheters).

Neutropenia is defined as an absolute neutrophil count (ANC) less than 500/μL (0.50 × 10^9/L) cells or an ANC less than 1000/μL (1.00 × 10^9/L) cells with a predicted decrease to less than 500/μL (0.50 × 10^9/L) cells over the next 48 hours. The ANC is calculated by multiplying the total WBC by the percentage of neutrophils (segmented neutrophils plus "bands"). Fever is defined as a single oral temperature greater than or equal to 38.3°C (101°F) or a temperature greater than or equal to 38.0°C (100.4°F) for at least 1 hour. The combination of these two factors defines FN.[16-18] The risk of infection during the period of neutropenia depends primarily on two factors:

- The duration of the neutropenia (time period of ANC < 500/μL [0.50 × 10^9/L] cells)
- The severity of the neutropenia (lowest ANC level reached [nadir])

A multitude of other risk factors for FN have been identified (Table 99–5).[19] Many of these are also risk factors for poor outcome in patients who experience FN. Cancer drug therapy regimens are also categorized as being high risk (more than 20% incidence of FN reported in clinical trials) or intermediate risk (10%–20% risk of FN reported in clinical trials). Similar to the approach to the prevention of CINV, it is important to consider both the regimen and patient-specific risk factors when determining whether a patient should receive prophylactic therapy for FN.

It is clear that patients with FN represent a heterogeneous group. Some patients are at lower risk and could potentially be treated as outpatients, thereby avoiding the risk and cost of hospitalization. The Multinational Association for Supportive Care in Cancer (MASCC) has validated a risk assessment tool that assigns a risk score to patients presenting with FN (Table 99–6).[19] Patients with a risk-index score greater than or equal to 21 are identified as low risk and candidates for outpatient therapy (discussed under section Treatment).

PREVENTION

Three primary modalities for preventing infection in patients who are expected to become neutropenic have been utilized, the first of which is the least expensive and simplest:

- Vigilant hand hygiene
- Prophylactic antibiotics
- Colony-stimulating factors (CSFs)

Table 99–5

Risk Factors for FN

Patient Related	Therapy Related
Age >65 years receiving full chemotherapy dose intensity	Disease, cancer type, and burden
Baseline low neutrophil or lymphocyte counts	History of extensive chemotherapy
Bone marrow involvement by tumor	Chemotherapy regimen • High-dose therapy (ie, stem-cell transplant) • Dose-dense therapy
Decreased hemoglobin or albumin level	Treatment intent (curative vs. palliative)
Elevated LDH	> 20% incidence of FN reported in clinical trials with treatment regimen
HIV infection	10%–20% incidence of FN reported in clinical trials with treatment regimen plus presence of patient-specific risk factors
Liver dysfunction (bilirubin >2.0 mg/dL)	
MASCC Risk Index Score < 21	
Poor performance status	
Prior chemotherapy or radiation therapy	
Persistent neutropenia	
Recent surgery and/or open wounds	
Renal dysfunction (creatinine clearance <50 ml/min)	

FN, febrile neutropenia; LDH, lactate dehydrogenase; MASCC, Multinational Association for Supportive Care in Cancer.

Data from The National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Prevention and Treatment of Cancer-Related Infections. V.2.2020. Available from: https://www.nccn.org/professionals/physician_gls/pdf/infections.pdf. Accessed August 17, 2020.

The advantages and disadvantages of these strategies are discussed individually in the following sections.

Hand Hygiene

As previously discussed, most infections in neutropenic patients are a result of endogenous flora; however, prevention of further acquisition of environmental pathogens is also important. Patients who are or will become neutropenic should practice careful handwashing and avoid contact with people who neglect hand hygiene. Although practice guidelines do not advocate for a "neutropenic diet" (avoiding ingestion of certain fresh fruits and vegetables as well as unprocessed dairy products), this is a common clinical advice given to patients despite the lack of strong evidence that following such a diet will reduce the risk of infection-related morbidity and mortality.[18] Evidence suggests that following a "neutropenic diet" does not have a lower incidence of infection.[20] Therefore, the focus should be on adherence to safe food handling, preparation, and storage guidelines set by the US Food and Drug Administration (FDA) to reduce food-borne infections. Practitioners should also engage in vigilant hand hygiene after each patient encounter to limit the spread of infections between patients.[17]

Prophylactic Antibiotics

Routine antibacterial prophylaxis is controversial and has been attempted primarily with sulfamethoxazole–trimethoprim (SMZ-TMP) and quinolones. SMZ-TMP offers improved prophylaxis against gram-positive organisms compared to the majority of

Table 99–6

MASCC Risk-Index for Identifying Low-Risk Patients with FN[a]

Characteristic	Score
Burden of FN with no or mild symptoms[b]	5
No hypotension (ie, systolic blood pressure > 90 mmHg)	5
No chronic obstructive pulmonary disease[d]	4
Solid tumor or hematologic malignancy without fungal infection[e]	4
No dehydration requiring parenteral fluids	3
Burden of FN with moderate symptoms[b]	3
Outpatient status	3
Age < 60 years[c]	2

[a] Note: Maximum score is 26. A risk-index score of ≥ 21 indicates that the patient is likely to be at low risk for complications and morbidity.

[b] Burden of febrile neutropenia refers to the general clinical status of the patient as influenced by the febrile neutropenic episode. It should be evaluated on the following scale: no or mild symptoms (score, 5), moderate symptoms (score, 3), and severe symptoms or moribund (score, 0). Scores of 3 and 5 are not cumulative.

[c] Does not apply to patients aged ≤ 16 years.

[d] Chronic obstructive pulmonary disease means active chronic bronchitis, emphysema, decrease in forced expiratory volumes, or need for oxygen therapy and/or steroids and/or bronchodilators requiring treatment at the presentation of the febrile neutropenic episode.

[e] Previous fungal infection means demonstrated fungal infection or empirically treated suspected fungal infection.

FN, febrile neutropenia; MASCC, Multinational Association for Supportive Care in Cancer.

From Klastersky J, Paesmans M. The Multinational Association for Supportive Care in Cancer (MASCC) risk index score: 10 years of use for identifying low-risk febrile neutropenic cancer patients. Support Care Cancer. 2013;21(5):1487–1495.

Clinical Presentation and Diagnosis of FN[16,17]

General

- Only 50% of patients with FN have a clinically documented infection.
- Only 25% of patients with FN have a microbiologically documented infection.

Signs and Symptoms

- Fever is typically the only sign of infection, although septic patients may have chills.
- Infected catheter sites may be erythematous and tender to the touch.

Laboratory Tests

- CBC with differential
- Two blood cultures from each access site (peripheral and central), urinalysis, urine culture, chest X-ray, sputum cultures

Other Diagnostic Tests

- Detailed physical examination of the oral mucosa, sinuses, skin, catheter access sites, perineal area (no rectal examination because of the risk of bacteremia)

quinolones; quinolones are more effective prophylaxis against gram-negative infections. The Infectious Diseases Society of America (IDSA), American Society of Clinical Oncology (ASCO), and National Comprehensive Cancer Network (NCCN) guidelines recommend fluoroquinolone prophylaxis in patients who are at intermediate and high risk for neutropenia lasting more than 7 days.[16,17] Routine antibiotic prophylaxis is not recommended for low-risk patients because of the lack of a clear benefit on mortality rates and concerns regarding increasing antibiotic resistance. One exception is that SMZ-TMP is recommended for prophylaxis of *Pneumocystis jiroveci* (formerly *Pneumocystis carinii*) pneumonitis (PJP) in all at-risk patients (i.e., hematopoietic cell transplant recipients, AIDS, receiving the predisone equivalent of 20 mg or more daily for 4 or more weeks), regardless of the presence of neutropenia.[16,17]

Two systematic reviews with over 110 trials and involving more than 13,000 patients demonstrated the benefits of prophylactic antibiotics compared to no prohylaxis.[21,22] Patients receiving either fluoroquinolone or SMZ-TMP had lower rates of bacteremia, fever, infection, and infection-related mortality and in one analysis all-cause mortality.[21,22] Of note, the use of prophylactic antibiotics did not increase the patients' risk for *Clostridioides difficile* infection.[21,22] However, most of these studies were conducted in patients with hematologic malignancies (an inherently high-risk group). Although two additional randomized trials in patients with both solid tumors and hematologic malignancies demonstrated lower rates of FN, infection, and hospitalization with oral prophylactic levofloxacin compared with placebo,[23,24] both were significantly criticized for methodological concerns and theoretical concerns about drug resistance and effectiveness of early treatment in low-risk patients. NCCN, ASCO, and IDSA only recommend prophylactic fluoroquinolone (preferred levofloxacin) for patients with expected duration of neutropenia (defined as an ANC < 1000/μL [1.00×10^9/L]) for more than 7 days because of the:

- Unknown long-term consequences on the development of resistant organisms
- Emergence of *Clostridioides difficile* and methicillin-resistant *Staphylococcus aureus* (MRSA) from fluoroquinolone overuse
- Ability to treat lower-risk patients on an outpatient basis, reducing the need for prophylactic antibiotics

In summary, the use of prophylactic quinolones in patients who are at intermediate and high risk for infection (ie, hematologic malignancies receiving high-dose chemotherapy for allogeneic stem-cell transplant) is reasonable; however, use should not be routine for low-risk patients. If prophylactic quinolone use is adopted, changes in local patterns of resistance should be closely monitored. If patients are intolerant to fluoroquinolone therapy, SMZ-TMP or a third-generation cephalosporin may be considered.

Colony-Stimulating Factors

The colony-stimulating fractors (CSFs) stimulate the maturation and differentiation of neutrophil precursors. Four agents are currently approved for use in the United States (Table 99–7). The prophylactic use of these agents decreases days of hospitalization and use of empiric antibiotics by shortening the duration of severe neutropenia (defined as ANC less than 500/μL [0.50×10^9/L]). There is little to no effect on the depth of neutrophil nadir. A meta-analysis found that the use of prophylactic granulocyte CSF (either filgrastim or pegfilgrastim) results in a 46% risk reduction of FN and a 48% risk reduction in infectious mortality, although

Table 99–7

Overview of CSF

Agent	Effector Cell(s)	Dosage	Common Adverse Effects	Comments[a]
Filgrastim (G-CSF, Neupogen; filgrastim-sndz, Zarzio; tbo-filgrastim, Granix; filgrastim-aafi, Nivestym)	Neutrophil	5 mcg/kg/day SC or IV or round to 300- *or* 480-mcg vial size	Bone pain (~25%)	Begin 1–3 days after chemotherapy
Pegfilgrastim (Neulasta; Neulasta On-body Injector; pegfilgrastim-apgf, Nyvepria; pegfilgrastim-bmez, Ziextenzo; pegfilgrastim-cbqv, Udenyca; pegfilgrastim-jmdb, Fulphila)	Neutrophil	6 mg SC once *or* Apply 1 device once	Bone pain (~25%)	Self-mediated clearance via neutrophils Once per cycle dosing Administer 1–3 days after chemotherapy
Sargramostim (Leukine GM-CSF)	Neutrophil, eosinophil, macrophage	250 mcg/m^2/day SC or IV or round to 250- *or* 500-mcg vial size	First dose effect (hypotension, flushing) Low-grade fever Bone pain Injection site skin reaction	Indicated for use after induction chemotherapy in older patients with AML Limited experience and lack of FDA approval for prevention of FN

[a] No renal or hepatic dose adjustments are required for any product listed in this table.

AML, acute myeloid leukemia; FDA, Food and Drug Administration; FN, febrile neutropenia; G-CSF, granulocyte colony-stimulating factor; GM-CSF, granulocyte-macrophage colony-stimulating factor; SC, subcutaneous.

absolute differences are small (3.3% vs 1.7%).[25] A more recent meta-analysis also found that a small (7%) but statistically significant reduction in the relative risk of all-cause mortality was found for patients treated with G-CSF prophylactically, with the benefit (11%) greater for patients receiving dose-dense regimens.[26] It is critical to note that patients who receive these agents may still experience FN despite the risk reduction. The primary limitation of the use of these agents is cost, and in fact, ASCO identified inappropriate G-CSF use as one of the "Top 5" interventions clinicians can make to reduce cancer care costs without compromising patient care.[27] Use of biosimilar filgrastim offers significant cost saving over standard filgrastim or pegfilgrastim and would be the most cost-efficient approach to prophylaxis.[28] CSFs are recommended beginning with the first cycle (primary prophylaxis) of chemotherapy when the risk of FN is greater than or equal to 20%, regardless of whether the goal of therapy is curative or palliative.[29] This is the point where the use of CSFs is cost effective when balanced against the cost of hospitalization and antimicrobials. Secondary prophylaxis refers to the subsequent prophylactic use of a CSF after a patient has had an episode of FN. This strategy should be used especially when the chemotherapy is being given in patients with the intention of cure (i.e., Hodgkin lymphoma, early breast cancer). In this circumstance, administration of full doses of chemotherapy on time without delays has been shown to improve patient outcomes.[25,26]

Although generally well tolerated, CSFs may cause bone pain in approximately 25% of patients. This may be managed with acetaminophen or nonsteroidal anti-inflammatory drugs (NSAIDs), although attention to the platelet count is warranted with the use of NSAIDs. Sargramostim in particular may result in low-grade fever and myalgias, perhaps as a result of its wider pattern of effector cell stimulation.[29]

TREATMENT

Desired Outcomes

Because rapid death may occur with certain infections in neutropenic patients, prompt and emergent treatment is indicated. The primary goal is to prevent morbidity and mortality during the neutropenic period. This is accomplished by effectively treating subclinical or established infections.

General Approach to Treatment

KEY CONCEPT A risk assessment should be performed at presentation of FN to identify low-risk patients for potential outpatient treatment (see Table 99–6). Patients who do not meet low-risk criteria should be hospitalized for parenteral administration of broad-spectrum antibacterials. The IDSA has published evidence-based guidelines for the management of FN (Figure 99–1).[16] The choice of initial antimicrobial agent(s) depends on the following factors:

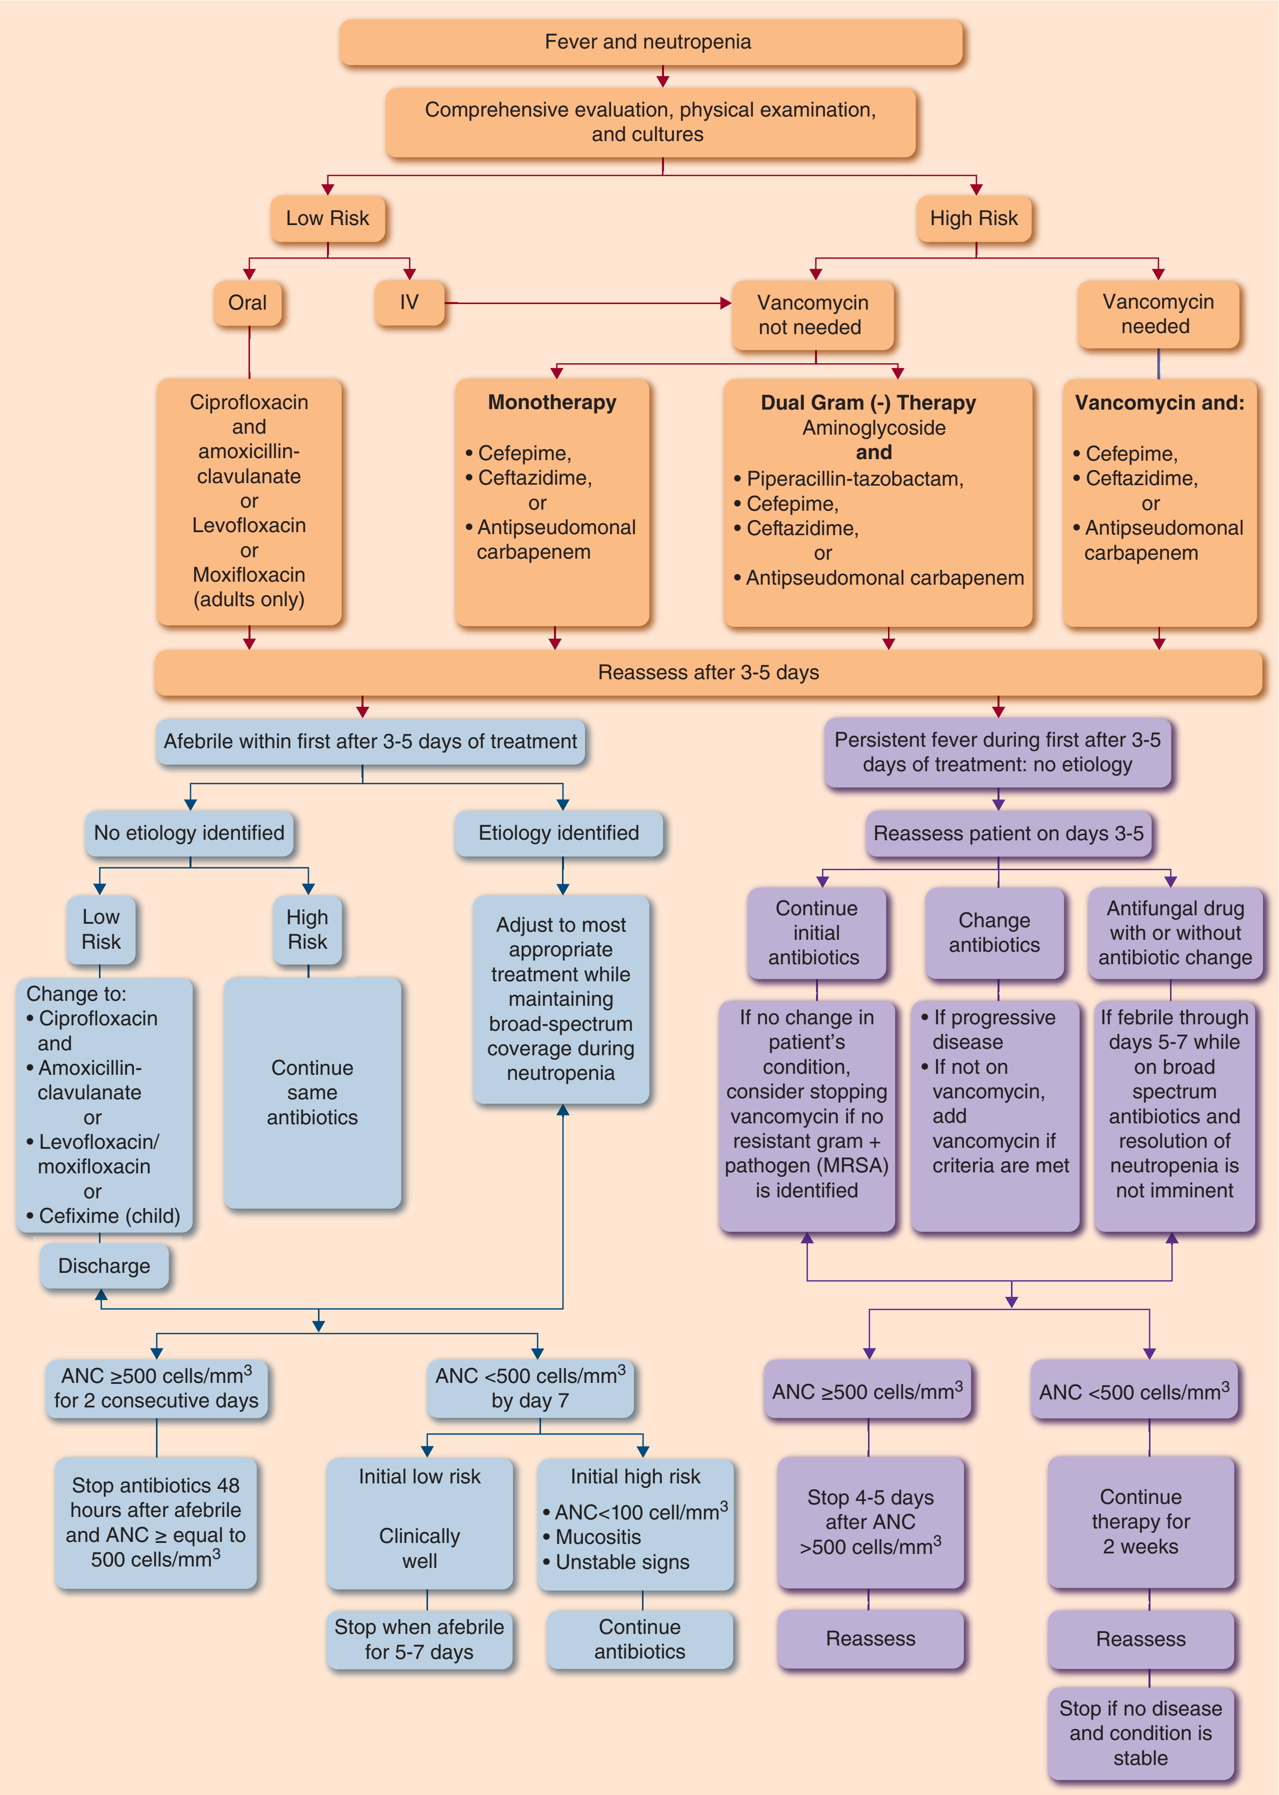
- Presence of a central venous catheter
- Drug allergies
- Concurrent renal dysfunction or use of nephrotoxic agents
- Use of prophylactic antibiotics
- Institutional and/or community susceptibility patterns
- Cost

KEY CONCEPT The administration of empiric therapy should begin immediately after cultures are taken. Therapy should not be withheld until after culture results are obtained.

As illustrated in Figure 99–1, specific criteria exist for the addition of vancomycin for coverage of resistant gram-positive organisms or agents for coverage of fungal infections. Additional agents are necessary in the setting of continued fever or declining clinical status in neutropenic patients. In general, all empiric therapy is continued until recovery of the ANC to levels above 500 cells/μL (0.500×10^9/L) in patients with negative culture results. If a specific etiology is identified, appropriate therapy should generally be continued until 7 days after neutropenia resolves. Specific regimens with recommended dosages are summarized in Table 99–8.

▶ *Nonpharmacologic Therapy*

Prevention of infection is key. Handwashing is critical in the prevention of disease transmission. It is also important to ensure



Fever and neutropenia
Comprehensive evaluation, physical examination, and cultures
Low Risk
High Risk
Oral

Table 99–8

Dosing Guidelines for Empiric Antimicrobial Agents in FN

Regimen Type	Agents and Dosing[a]	Comments
Antibacterial		
β-Lactam monotherapy	Cefepime 2 g IV every 8 hours Ceftazidime 2 g IV every 8 hours Imipenem 500 mg IV every 6 hours Meropenem 1 g IV every 8 hours or 500 mg IV every 6 hours Piperacillin–tazobactam 4.5 g IV every 6 hours	Although piperacillin–tazobactam is not recommended in the IDSA guidelines, recent data demonstrate equivalence to other monotherapy and dual therapy regimens. All these agents require renal dose adjustment, and none requires adjustment in hepatic dysfunction.
Dual therapy with antipseudomonal β-lactam plus aminoglycoside	Cefepime, ceftazidime, imipenem, meropenem, piperacillin–tazobactam (above dosages), and either amikacin, gentamicin or tobramycin (consider extended interval dosing)	Extended interval dosing, gentamicin/tobramycin 7 mg/kg V daily or amikacin 15 mg/kg IV daily. Traditional dosing: gentamicin or tobramycin 2 mg/kg or amikacin 5 mg/kg loading dose followed by doses adjusted by serum concentrations; once-daily dosing of aminoglycosides may be used. Amikacin, gentamicin, and tobramycin require renal dose adjustment but are dosed based on serum levels. No dose adjustments are for hepatic dysfunction.
Empiric regimens containing vancomycin	Cefepime, ceftazidime, imipenem, meropenem (above dosages) and vancomycin 0.5–1 g every 6–12 hours with or without aminoglycoside	Vancomycin dosages may be adjusted based on serum levels and are adjusted for renal disease and dialysis. No dose adjustment is recommended for hepatic dysfunction.
Vancomycin intolerance or contraindications	Daptomycin 6–12 mg/kg IV every 24 hours, higher doses can be used for specific indications	Both agents are effective for the treatment of vancomycin-resistant enterococci (VRE). Daptomycin (8–12 mg/kg) is not FDA indicated for VRE but is used clinically. Daptomycin frequency adjustment instead of dose reduction needed for renal dysfunction and dialysis. Weekly creatine phosphokinase (CPK) to monitor for rhabdomyolysis. Daptomycin is inactivated by pulmonary surfactants.
	Linezolid 600 mg IV/PO every 12 hours	Linezolid requires no dose adjustment for renal or hepatic dysfunction. Hematologic toxicy may occur, thrombocytopenia most common, typically after 2 weeks of therapy. Caution use with selective serotonin reuptake inhibitors due to Serotonin syndrome.
Dual therapy containing fluoroquinolone	Ciprofloxacin 400 mg IV every 8 hours and piperacillin–tazobactam or ceftazidime (above dosages)	Cannot be used in patients who receive fluoroquinolone prophylaxis. Dose adjusted in renal disease and dialysis, but not for hepatic dysfunction.
Low-risk oral regimen	Ciprofloxacin 750 mg po every 12 hours and amoxicillin–clavulanate 875 mg po every 12 hours	For patients with MASCC scores ≥ 21 not receiving fluoroquinolone prophylaxis. Amoxicillin–clavulanate is adjusted in renal disease and dialysis but not hepatic dysfunction.
	Levofloxacin 500–750 mg po or IV daily Moxifloxacin 400 mg po or IV daily	Improved gram-positive activity compared to ciprofloxacin. Levofloxacin has limited to no activity against enteric anaerobes. Moxifloxacin has insufficient activity against Pseudomonas.
Pneumocystis jiroveci	Sulfamethoxazole-trimethoprim (SMZ-TMP) Prophylaxis: single strength tablet orally daily or double strength tablet 3 times per week Treatment: 15/mg/kg/day in divided doses every 6–8 hours based on the TMP component	Monitor for renal insufficiency, myelosuppression, hepatotoxicity, and hyperkalemia. Interactions with methotrexate. Dose adjusted in renal disease and dialysis but not for hepatic dysfunction.
Antifungal		
Amphotericin B deoxycholate	0.5–1 mg/kg IV daily	Premedication with acetaminophen and diphenhydramine; 500-mL normal saline boluses before and after. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis.
Liposomal amphotericin B	3–5 mg/kg IV daily	Lower incidence of nephrotoxicity and infusion reactions; more expensive. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis.
Anidulafungin	200 mg IV loading dose on day 1, then 100 mg IV daily	No dose adjustments required for renal or hepatic dysfunction or during dialysis.
Caspofungin	70 mg/kg IV loading dose on day 1 followed by 50 mg/kg IV daily	Dosage adjustment in hepatic dysfunction but not for renal disease or dialysis.
Micafungin	100–150 mg IV daily	No dose adjustments required for renal or hepatic dysfunction or during dialysis.
Fluconazole	400 mg IV or po daily	Dosage adjustment in renal disease or dialysis. No dose adjustment for hepatic dysfunction. *C. glabrata* is associated with variable resistance and requires higher doses.

(Continued)

Table 99–8

Dosing Guidelines for Empiric Antimicrobial Agents in FN (*Continued*)

Regimen Type	Agents and Dosing[a]	Comments
Itraconazole	200 mg po three times a day for the first three days, then 200 mg po two times a day	No dose adjustments required for renal or hepatic dysfunction or during dialysis. H_2-antagonists and proton pump inhibitors may inhibit absorption. Oral liquid formulation is preferred for absorption.
Isavuconazole	372 mg IV or po loading dose every 8 hours for 2 days followed by 372 mg IV or po daily	Can be considered in patients intolerant or refractory to first-line antimold therapy. No dose adjustments required for renal or hepatic dysfunction or during dialysis
Posaconazole	Prophylactic: 200 mg po three times a day with food 300 mg IV twice a day on day 1, then 300 mg IV daily Salvage: 200 mg po four times a day with food; then 400 mg po two times a day when stable	Not FDA-approved for primary or salvage therapy for invasive fungal infections but used clinically; no dose adjustments required for renal or hepatic dysfunction or during dialysis.
Voriconazole	6 mg/kg IV loading dose every 12 hours on day 1 followed by 4 mg/kg po or IV every 12 hours	Dosage adjustment in hepatic dysfunction; IV formulation contraindicated if creatinine clearance < 50 mL/min (0.83 mL/s); multiple drug interactions.

[a]Dosing for adult patients; adjust doses for renal dysfunction.

AML, acute myeloid leukemia; FDA, Food and Drug Administration; IDSA, Infectious Diseases Society of America; IV, intravenous; MDS; myelodysplastic syndrome; NCCN, National Comprehensive Cancer Network; po, oral; National Comprehensive Cancer Network. that patients receive annual influenza vaccines and have had a pneumococcal and meningococcal vaccine, and neutropenic patients should avoid individuals with active respiratory infections. Indwelling catheters are often sources of infection; however, the IDSA acknowledges that catheters do not always need to be removed.[16] Catheters should be removed in the following circumstances: established tunnel infection (subcutaneous tunnel or periport infection, septic emboli, endocarditis, hypotension associated with catheter use, or a nonpatent catheter), sepsis with hemodynamic instability, recurrent infection, or no response to antibiotics within 2 or 3 days. Wound debridement should also be performed upon catheter removal. In the setting of peripheral blood stem-cell or bone marrow transplant, the Centers for Disease Control and Prevention recommends the use of high-efficiency particulate air (HEPA) filtration systems in patient rooms, and the NCCN suggests that HEPA filters are reasonable to be considered for other patients who experience prolonged neutropenia. HEPA filters are likely to be most useful in preventing mold infections. Although several small studies have attempted to evaluate the effectiveness of isolation of neutropenic patients as a mechanism for infection prevention, no clear data are available to support this practice, nor are neutropenic diets, footwear exchange, and other dietary interventions.[16,17]

▶ *Pharmacologic Therapy*

There are two primary choices for the initial management of high-risk FN: monotherapy and dual therapy (see Figure 99–1). Both regimens have been shown to be equivalent in randomized studies and meta-analyses. Monotherapy avoids the nephrotoxicity of the aminoglycosides and is potentially less expensive but lacks significant gram-positive coverage and may increase selection of resistant organisms. Dual therapy provides synergistic activity, decreased resistance, and dual coverage of *Pseudomonas aeruginosa* but also lacks gram-positive coverage and requires therapeutic monitoring for aminoglycosides. The choice between monotherapy and dual therapy is usually provider and institution preference, although dual therapy may be preferred in an acutely symptomatic patient (eg, hypotensive) or cases of bacterial resistance.

Vancomycin adds broad-spectrum gram-positive coverage; however, the increasing emergence of vancomycin-resistant organisms (i.e., *Enterococcus* spp.) prompts conservative use of this medication. Vancomycin should only be included as part of the initial therapy if patients are at high risk for a serious gram-positive infection such as the following clinical situations:

- Soft tissue infection (particularly in regions where MRSA infections is common)
- Blood cultures positive for gram-positive bacteria before final identification and susceptibility testing
- Clinically unstable (eg, hypotension or shock), pending the results of cultures
- Known colonization with penicillin/cephalosporin-resistant pneumococci or MRSA
- Clinically apparent, serious IV catheter-related infection

Vancomycin may be added to the empiric regimen after 3 to 5 days in persistently febrile patients or if cultures reveal gram-positive organisms. Vancomycin should be reassessed within 2 to 3 days of initiation and changed if the gram-positive organism is susceptible to other antibacterials or discontinued in patients with persistent fever after 3 days with negative culture results. Linezolid, quinupristin–dalfopristin, tigecycline, and daptomycin may be used in cases of vancomycin-resistant organisms or if vancomycin is not an option because of drug allergy or intolerance.

Empiric antifungal agents are typically added in persistently febrile patients after 5 to 7 days, especially if continued neutropenia is expected. Amphotericin B has historically been the drug of choice because of its broad-spectrum activity against both yeast (*Candida* spp.) and mold (*Aspergillus* spp.)

infections. Because frequent toxicity (nephrotoxicity, infusion reactions) limits the use of amphotericin B, less toxic alternatives have been studied. Lipid formulations of amphotericin provide decreased toxicity, and liposomal amphotericin B (AmBisome) has been shown to be equivalent to conventional amphotericin B as empiric therapy but is significantly more expensive. Echinocandins are active against *Candida* and *Aspergillus* species. Caspofungin is equivalent with less toxicity compared with liposomal amphotericin B in a randomized trial and is FDA-approved for this indication. Micafungin was compared to voriconazole in a randomized trial, and no significant difference in clinical efficacy was detected. Anidulafungin has not been studied specifically for empirical antifungal therapy in febrile neutropenia, but clinical experts consider it likely be effective based on data from the other echinocandins.[17] Voriconazole is equivalent to liposomal amphotericin in mortality, but response was improved in those receiving liposomal amphotericin. Voriconazole does not have an indication, but it is sometimes used. Itraconazole has also been used in some institutions, but its use is complicated by poor bioavailability of oral preparations and numerous drug interactions. Posaconazole is FDA-approved for the prevention of invasive *Aspergillus* and *Candida* infections in patients at high-risk due to being severely immunocompromised (i.e., prolonged neutropenia; hematopoietic stem-cell transplant patients with graft-versus-host-disease). The oral suspension of posaconazole is also approved for the treatment of local oropharyngeal Candidiasis. It is not FDA-approved as primary or salvage therapy for the treatment of invasive fungal infections, but it is approved by the European Union for invasive aspergillosis and other fungal infections that are refractory to standard antifungal agents. Isavuconazonium sulfate is FDA-approved for invasive aspergillosis and mucormycosis. In clinical trials, isavuconazonium sulfate was shown to be noninferior to voriconazole for invasive aspergillosis. Posaconazole and isavuconazonium sulftate should be considered for invasive, refractory fungal infections or those with intolerance to amphotericin B formulations.[17]

As stated earlier, low-risk patients fulfilling the MASCC criteria (see Table 99–6) may be treated empirically as an outpatient with a regimen combining amoxicillin–clavulanic acid and ciprofloxacin or ciprofloxacin and clindamycin in penicillin-allergic patients. Monotherapy with either levofloxacin or moxifloxacin is an alternative, but only in to low-risk patients who have not received a quinolone therapy previously as prophylaxis. The CSFs should not routinely be used for treatment of FN in conjunction with antimicrobial therapy.[16,17] However, the use of CSFs in certain high-risk patients with hypotension, documented fungal infection, pneumonia, or sepsis is reasonable. A meta-analysis demonstrated that hospitalization and neutrophil recovery are shortened and infection-related mortality is marginally improved with CSF prophylaxis in high-risk patients.[25] As with prophylactic use of these agents, cost considerations limit their use to high-risk patients.

OUTCOME EVALUATION

The success of the treatment of FN depends on the adequate recovery of the ANC and either optimal antimicrobial coverage of identified organisms or empiric coverage of unidentified organisms. Daily patient assessment should include an evaluation of response to empiric antimicrobial therapy, in terms of changes in sign and/or symptoms of infection and fever trends. Monitor the complete blood count (CBC) with differential and $T_{\max}$ (maximum temperature during previous 24 hours) daily. Assess renal and hepatic function at least twice weekly, especially in patients receiving nephrotoxic agents. Vital signs should be taken every 4 hours. Follow up on blood and urine culture results daily because many cultures do not become positive for several days. Assess the patient daily for pain that may indicate an infectious source. Conduct daily physical examination of common sites of infection. Repeat cultures and chest X-ray in persistently febrile patients and culture developing sources of infection (ie, stool cultures for diarrhea).

CARDIOVASCULAR COMPLICATIONS: SUPERIOR VENA CAVA SYNDROME (SVCS)

INTRODUCTION

Superior vena cava syndrome (SVCS) is a relatively rare complication that may occur in patients with cancer. SVCS is rarely immediately life threatening except in patients with airway compromise and/or laryngeal or cerebral edema. However, rapid recognition of typical presenting symptoms facilitates referral for tissue diagnosis (if unknown) and treatment.

EPIDEMIOLOGY AND ETIOLOGY

SVCS occurs in around 15,000 patients per year, 90% of which are caused by malignancy. Specific cancers most commonly associated with SVCS are listed in Table 99–9. Lung cancer is the most frequent cause, of which small cell lung cancer (SCLC) is the most frequent subtype associated with SVCS. In fact, SVCS is the presenting symptom for the diagnosis of lung cancer in approximately 60% of the cases.[31] This is thought to be because of its predilection for the central and perihilar areas of the lung. Interestingly, right-sided lung cancers are four times more likely than left-sided lesions to cause SVCS. Mediastinal masses from lymphomas are the second most common cause.

Clinical Presentation and Diagnosis of SVCS[30]

General

- Presentation depends on the degree of SVCS obstruction.
- Almost complete obstruction is necessary to demonstrate symptoms.

Signs and Symptoms

- Most common: swelling of face, neck, and upper extremity edema; dyspnea; cough; dilated upper extremity veins; orthopnea.
- Less common: hoarseness, dysphagia, dizziness, headache, lethargy, chest pain.
- Patients with elevated ICP may have mental status changes.
- Patients with airway obstruction may have shortness of breath.

Diagnostic Tests

- Tissue biopsy to determine underlying malignancy (if unknown), chest X-ray, CT scan, **bronchoscopy, mediastinoscopy**.

Table 99–9

Tumors Most Commonly Associated with SVCS

Cause	Frequency (%)
Non–small cell lung cancer	50
Small-cell lung cancer	22
Lymphoma	12
Metastatic cancer (especially breast)	9
Germ cell tumor	3
Thymoma	2
Mesothelioma	1

Data from Wilson LD, Detterbeck FC, Yahalom J. Superior vena cava syndrome with malignant causes. N Engl J Med. 2007;356(8):1862–1869.

The most common nonmalignant etiology of SVCS is catheter-related thrombosis, primarily caused by the increasing use of central access devices. Other causes include benign teratoma, tuberculosis, silicosis, and sarcoidosis.

PATHOPHYSIOLOGY

The SVC is the primary drainage vein for blood return from the head, neck, and upper extremities. It is a relatively thin-walled vein that is particularly vulnerable to obstruction from adjacent tumor invasion or thrombosis. The obstruction leads to elevated venous pressure, although collateral veins partially compensate. This is one reason for the relatively slow onset of the classic symptoms of SVCS. In fact, 75% of patients have signs and symptoms for more than one week before seeking medical attention.[30]

CLINICAL PRESENTATION AND DIAGNOSIS TREATMENT

Desired Outcomes

KEY CONCEPT The primary goal of treatment of SVCS is to relieve the obstruction of the SVC by treating the underlying malignancy. In the case of SVCS caused by thrombosis, the goal is to eliminate the thrombus and prevent further clot formation. Resolution of the obstruction will rapidly relieve symptoms and restore normal SVC function. The final goal of therapy is to avoid potentially fatal complications of SVCS such as cerebral edema from rapid increases in intracranial pressure (ICP) and intracranial thrombosis or bleeding.

General Approach to Treatment

Because the majority of SVCS is not immediately life threatening, a tissue diagnosis (if malignancy is unknown) to specifically identify the cancer origin is critical because treatment approaches vary considerably according to tumor histology. Thus, therapy can typically be withheld until a definitive tissue diagnosis is established. While biopsy results are pending, supportive measures such as head elevation, diuretics, corticosteroids, and supplemental oxygen may be used.

▶ *Nonpharmacologic Therapy*

Radiation therapy is the treatment of choice for chemotherapy-resistant tumors such as non–small cell lung cancer (NSCLC) or in chemotherapy-refractory patients with SVCS. Between 70% and 90% of the patients experience relief of symptoms. Radiation therapy may also be combined with chemotherapy for chemotherapy-sensitive tumors such as SCLC and lymphoma. In the rare emergency situations of airway obstruction or elevated ICP, empiric radiotherapy before tissue diagnosis should be used. In most patients, symptoms resolve within 1 to 3 weeks.

Surgical options for the management of SVCS include stent placement and surgical bypass. SVC stenting may provide longer-term relief of symptoms than radiotherapy, so it is often used in the palliative care setting when chemotherapy has failed.[30] One disadvantage of SVC stenting is the need for anticoagulation, especially in patients at high risk for thrombosis. The role of surgical bypass is limited to patients with complete SVC obstruction or patients who are refractory to chemotherapy and radiotherapy; thus, it is rarely indicated.

▶ *Pharmacologic Therapy*

Cytotoxic chemotherapy is the treatment of choice for chemotherapy-sensitive tumors such as SCLC and lymphoma. As indicated earlier, chemotherapy may also be combined with radiotherapy, especially in patients with lymphoma who have bulky mediastinal lymphadenopathy.

Corticosteroids can be used to manage of SVCS, particularly in cases of lymphoma, because these tumors are inherently responsive to corticosteroid therapy. They are also helpful in the setting of respiratory compromise. Corticosteroids benefit patients who are receiving radiation therapy by reduction of local radiation-induced inflammation and patients with increased ICP. Dexamethasone 4 mg IV or by mouth every 6 hours is a frequently used regimen. The dosage should be tapered upon completion of radiation therapy or resolution of symptoms. The use of corticosteroid may impact the ability to obtain histology in cases in which the first biopsy is found to be insufficient.[31]

The role of diuretics in the management of SVCS is controversial. Although patients may derive symptomatic relief from edema, complications such as dehydration and reduced venous blood flow may exacerbate the condition. If diuretics are used, furosemide is most frequently used with diligent monitoring of the patient's fluid status and blood pressure.

In the case of thrombosis-related SVCS, anticoagulation is controversial because there is a lack of survival benefit. However, thrombolytics (i.e., alteplase) and anticoagulation with heparin and warfarin may be beneficial in patients with thrombosis caused by indwelling catheters if used within 7 days of onset of symptoms, although catheter removal may be required.[30]

OUTCOME EVALUATION

The major measure of outcome of treatment of SVCS is the relief of symptoms, regardless of the therapy used.

NEUROLOGIC COMPLICATIONS: SPINAL CORD COMPRESSION

INTRODUCTION

Although not typically life threatening, spinal cord compression is a true oncologic emergency because delays in treatment by mere hours may lead to permanent neurologic dysfunction. Practitioners must quickly recognize the signs and symptoms of this condition to facilitate rapid management strategies.

Clinical Presentation and Diagnosis of Spinal Cord Compression

General

- Once neurologic deficits appear, progression to irreversible paralysis may occur within hours to days.
- Around 30% to 50% of patients present with multiple sites of spinal involvement.

Signs and Symptoms

- Back pain is present in more than 90% of patients.
- Initially localized and increases in intensity over several weeks.
- Aggravated by movement, supine positioning, coughing, sneezing, neck flexion, straight leg raise, **Valsalva maneuver**, palpation of spine
- Sensory deficit
- Cervical spine compression: quadriplegia
- Thoracic spine compression: paraplegia
- Upper lumbar spine compression: bowel and bladder dysfunction (constipation and urinary retention) and abnormal extensor plantar reflexes
- Weakness

Diagnostic Tests

- MRI with gadolinium enhancement is the gold standard.
- X-rays may be helpful to identify bone abnormalities.

EPIDEMIOLOGY AND ETIOLOGY

Around 20,000 patients with cancer experience spinal cord compression in the United States every year, most of which involves the thoracic spine (~70%). Cancers that inherently metastasize to the bone (ie, breast, prostate, and lung) are the most frequent underlying malignancies associated with this complication. Most spinal cord compression occurs in patients with a known malignancy; however, 20% to 25% of cases occur as the initial presentation of cancer, especially in patients with non-Hodgkin lymphoma, multiple myeloma, and lung cancer.[32]

PATHOPHYSIOLOGY

The spinal cord emerges from the brain stem at the base of the skull and terminates at the second lumbar vertebra. The thoracic spine is most vulnerable to cord compression because of natural kyphosis and because the width of the thoracic spinal canal is the smallest among the vertebrae. Most spinal cord compression is caused by adjacent vertebral metastases that compress the spinal cord or from pathologic compression fracture of the vertebra. This results in significant edema and inflammation in the affected area.

Patients with spinal cord compression are in acute, severe back and/or neck pain and may present to the emergency department for evaluation. Diagnosis is made based on symptoms and imaging studies that show fractured vertebrae.

TREATMENT

Desired Outcomes

KEY CONCEPT Because patients with cancer and spinal metastases are generally incurable, the primary goal of treatment of spinal cord compression is palliation. The most important prognostic factor for patients presenting with spinal cord compression is the degree of underlying neurologic dysfunction. Only around 10% of patients who present with paralysis are able to ambulate after treatment.[32] Therefore, the goals of treatment are recovery of normal neurologic function, local tumor control, pain control, and stabilization of the spine. Therapeutic options depend primarily on the following factors:

- Underlying malignancy
- Prior therapies
- Stability of the spine at presentation
- Overall patient prognosis

▸ *Nonpharmacologic Therapy*

Radiation therapy (RT) at 20 Gy in 5 daily fractions or 30 Gy in 10 daily fractions is generally considered to be the treatment of choice for most patients. Exceptions to this include patients with prior radiation to the treatment site and patients with inherently radio-resistant tumors (i.e., melanoma, renal cell carcinoma). The radiation field should include two vertebral bodies above and below the involved area.

Surgery for spinal cord compression typically involves either laminectomy for posterior lesions or decompression with fixation. Surgery should be considered in patients with metastatic spinal cord compression, spinal instability, or failed prior RT, with the main aim to preserve neurological function, reduce pain, and stabilizing the weakened vertebral column. Surgery followed by radiation therapy may be superior to radiotherapy alone in terms of increased ambulation time after treatment, maintenance of continence, and rates of nonambulatory patients becoming ambulatory.[32] Surgery is also useful for establishing a tissue diagnosis in cases of unknown malignancy. Overall, the risks and benefits of surgery must be weighed against the expected prognosis of the patient in light of the significant rehabilitation required after surgery.

▸ *Pharmacologic Therapy*

Corticosteroids play a vital role in the management of spinal cord compression. Dexamethasone is most frequently used to reduce edema, inhibit inflammation, and delay the onset of neurologic complications. Early use of corticosteroids is crucial, ideally within 12-hours of symptom onset, with definitive therapy with RT or surgery to follow.[32] Significant controversy exists regarding the optimal dosing of dexamethasone though both the UK and Canadian guidelines recommend 16 mg orally or IV immediately, followed by a short course of 8 mg by mouth or intravenously twice daily. Higher doses may be used in cases of rapidly progressing symptoms, but adverse effects, including GI bleeding and psychosis, are more severe and have not shown to be beneficial. Steroids should be continued during radiation therapy and then tapered appropriately.

Pain management is also of critical importance in patients with spinal cord compression. Although dexamethasone will provide some benefit, opioid analgesics should also be used and titrated rapidly to achieve adequate pain control.

OUTCOME EVALUATION

Patients who receive definitive treatment with radiation and/or surgery generally derive benefit within days.

Clinical Presentation and Diagnosis of Brain Metastasis

General

- Almost all patients with brain metastases are symptomatic.
- New cerebral neurologic symptoms in a cancer patient should initiate evaluation for brain metastases.
- Other causes of brain lesions, including hemorrhage, infection, and infarct, should be ruled out.

Signs and Symptoms

- Headache (most common): May be of gradual onset or sudden in the case of hemorrhage
- Altered mental status: Loss of consciousness, irritability, confusion, cognitive impairment
- **Hemiparesis**, **aphasia**, **papilledema**, weakness, seizure, nausea, and vomiting

Diagnostic Tests

- MRI with contrast enhancement is the gold standard.
- CT scans may be used in patients with pacemakers but may miss small metastases.

COMPLICATIONS OF BRAIN METASTASES

INTRODUCTION

Brain metastases are among the most feared complications of cancer and generally carry a poor prognosis. One serious consequence of brain metastases is elevated ICP, which can rapidly lead to fatal intracranial herniation and death. Rapid identification of the signs and symptoms of brain metastases is critical to improve long-term outcome and avoid mortality. The signs and symptoms of brain metastasis can be confused with common psychological distress or other neurologic problems (eg, headaches) that may go unrecognized. It is important that patients who are suspected to have brain metastasis are quickly referred for appropriate management.

EPIDEMIOLOGY AND ETIOLOGY

Brain metastasis is the most common neurologic complication seen in patients with cancer. Approximately 170,000 patients develop brain metastases in the United States each year.[33] Many malignancies are frequently associated with brain metastases (Table 99–10). Although melanoma is the tumor type most likely to metastasize to the brain, brain metastases caused by lung and breast cancer are seen more often because they are among the most common cancers. In addition, brain metastases may be diagnosed at the same time as the primary malignancy. Around 80% of brain metastases occur in the cerebral hemispheres, 15% in the cerebellum, and 5% in the brain stem.

Table 99–10

Cancers Most Frequently Associated with Brain Metastases

Type of Cancer	Frequency (%)
Lung cancer	18–64
Breast cancer	2–21
Melanoma	4–16
Colorectal cancer	2–11
Hematologic malignancies (ie, leukemia)	~10 (primarily caused by leptomeningeal spread)

Data from Lin X, DeAngelis LM. Treatment of brain metastases. J Clin Oncol. 2015;33(30):3475–3484.

PATHOPHYSIOLOGY

A delicate balance of normal pressure is maintained in the brain and spinal cord by brain, blood, and cerebrospinal fluid. Because the brain is contained within a confined space (skull), any foreign mass contained within that space causes adverse sequelae. This results in either destruction or displacement of normal brain tissue with associated edema. Most brain metastases occur through hematogenous spread of the primary tumor and around 80% of patients have multiple sites of metastases within the brain.

TREATMENT

Desired Outcomes

Therapeutic modalities used for the management of brain metastases may be divided into symptomatic management and definitive management. **KEY CONCEPT** The goals of treatment of brain metastases are to manage symptoms by reducing cerebral edema, treat the underlying malignancy both locally and systemically, and improve survival.

General Approach to Treatment

Patients with brain metastases have a poor prognosis. Untreated patients generally have a median survival of 1 month. Recent advances in drug therapy and radiation/stereotactic radiosurgery now yield median survival times as long as 13.5 months in some patients with solitary brain lesions and good performance status. The choice of treatment depends primarily on the status of the patient's underlying malignancy and the number and sites of brain metastases. The primary definitive treatments for brain metastases are surgery and radiation therapy. Pharmacologic modalities such as corticosteroids and antiepileptics are primarily used to control symptoms, although cytotoxic chemotherapy plays a limited role in the management. Monoclonal antibodies have a large molecular size and, therefore, would not be expected to cross the blood–brain barrier (BBB); however, BBB permeability may be enhanced due to physical disruption from the brain metastasis itself, and some of the targeted oral therapies have better BBB penetration. Immunotherapies have shown to confer benefits in some settings; however, the efficacy could be reduced by the concurrent use of corticosteroids.[34]

▸ *Nonpharmacologic Therapy*

Radiation therapy is the treatment of choice for most patients with brain metastases. Most patients receive whole-brain radiation (WBRT) because the majority of brain metastases are multifocal. Another method known as stereotactic radiosurgery provides intense focal radiation, typically using a **linear accelerator** or **gamma knife**, in patients who cannot tolerate surgery or have lesions that are surgically inaccessible (i.e., brain stem). Stereotactic radiosurgery is also often used for selected patients with up to three lesions that are each less than 4 cm.[33] WBRT can cause long-term problems with memory and cognitive function but this risk is less than that seen with declines due to brain disease, and thus, the benefits of WBRT outweigh the risks in appropriate patients. Because brain metastases can occur in up to 50% of patients with small cell lung cancer, prophylactic cranial irradiation (PCI) is recommended in patients with limited stage disease with good performance status who at least partially respond to chemotherapy to both prevent the development of brain metastases and prolong survival; there is conflicting evidence on the role of PCI in extensive stage SCLC though generally many patients will be offered treatment.[35] Furthermore, a recent randomized controlled trial has shown that PCI did not improve overall survival compared with routine surveillance and treatment of asymptomatic brain metastases upon detection.[36] Although other cancers can metastasize to the brain, the benefits of routine prophylactic cranial irradiation have only been demonstrated in studies conducted in patients with small cell lung cancer. For patients who receive PCI, prophylactic use of memantine is shown to preserve cognitive function in patients.[37]

Surgery plays a key role in the management of patients with brain metastases, particularly in patients whose systemic disease is well controlled and in patients with solitary lesions. Surgery may also benefit patients with multiple metastatic sites who have a single dominant lesion with current or impending neurologic sequelae.

▶ *Pharmacologic Therapy*

Corticosteroids are a mainstay in the management of brain metastases. They reduce edema that typically surrounds sites of metastases, thereby reducing ICP. A loading dose of dexamethasone 10 to 24 mg IV followed by 4 mg by mouth or IV every 6 hours or 8 mg by mouth twice daily is typically used. Symptom relief may occur shortly after the loading dose, although the maximum benefit may not be seen for several days (after definitive therapy).[38] Slow tapering of dexamethasone, over 3 days to 2 weeks, is recommended.

Mannitol is an agent that may be used in patients with impending cerebral herniation. Mannitol is an osmotic diuretic that shifts brain osmolarity from the brain to the blood. Doses of 100 g (1–2 g/kg) as an IV bolus should be used. Repeated doses are typically not recommended because mannitol may diffuse into brain tissue, leading to rebound increased ICP.

Approximately 20% patients with brain metastases may present with seizures and require anticonvulsant therapy. There is no evidence that a specific antiepileptic drug is more effective than another. Hence, the choice of anticonsulvant should be based on patient-related factors including the type of epilepsy, age, comorbidity, and concomitant drugs. Levetiracetam, which has fewer side effects and drug interaction potential, is currently the therapy of choice for management of seizures in patients with brain metastases.[39] Prophylactic anticonvulsants have frequently been used; however, current guidelines do not support this practice. Thus, because adverse effects and drug interactions are common, the routine use of prophylactic anticonvulsants is not recommended.

OUTCOME EVALUATION

The success of therapy is based on the ability to decrease symptoms, treat the underlying sites of disease within the brain, and prolong survival.

UROLOGIC COMPLICATIONS: HEMORRHAGIC CYSTITIS

INTRODUCTION

Hemorrhagic cystitis is defined as acute or insidious bleeding from the lining of the bladder. Although therapy with certain medications is the most common cause, it is also the most preventable. Once it occurs, hemorrhagic cystitis causes significant morbidity and mortality rates between 2% and 4%. This section focuses on preventive strategies for chemotherapeutic causes of hemorrhagic cystitis.

Table 99–11

Primary Causes of Hemorrhagic Cystitis

Pharmacologic	Nonpharmacologic
Cyclophosphamide	Pelvic irradiation
Chronic low doses	Viral infection
High doses used in BMT	CMV
Ifosfamide	Papovavirus
Intravesicular thiotepa	Herpes simplex virus
Chronic oral busulfan	Adenovirus
Anabolic steroids	

BMT, bone marrow transplantation; CMV, cytomegalovirus.

Data from Payne H, Adamson A, Bahl A, et al. Chemical- and radiation-induced hemorrhagic cystitis: current treatments and challenges. BJU Int. 2013;112(7):885–897.

EPIDEMIOLOGY AND ETIOLOGY

Numerous etiologies have been linked to hemorrhagic cystitis (Table 99–11).[40] Of these, the oxazaphosphorine alkylating agents (cyclophosphamide and ifosfamide) are most frequently implicated. Hemorrhagic cystitis is the dose-limiting toxicity of ifosfamide and predisposes patients with bladder cancer. Incidence rates vary considerably but generally range between 20% and 25% with high-dose (300 mg/m^2 or more) cyclophosphamide in the absence of prophylactic measures and even more commonly with ifosfamide. Chronic, low-dose oral cyclophosphamide as typically used in autoimmune disorders and chronic lymphocytic leukemia is infrequently associated with hemorrhagic cystitis. Cystitis occurs in 80% of patients treated with intravesicle Bacillus Calmette-Guerin (BCG) for bladder cancer, with 20% also experiencing hematuria.

Around 20% patients receiving pelvic irradiation may experience hemorrhagic cystitis, especially with concurrent cyclophosphamide. Notably, this toxicity can present acutely or long after treatment with radiation has ended (up to 15 years). Viral infections commonly associated with this condition most frequently occur in bone marrow transplant recipients who may also receive cyclophosphamide.

PATHOPHYSIOLOGY

Cyclophosphamide- or ifosfamide-induced damage to the bladder wall is primarily caused by their shared metabolite known as acrolein. Acrolein causes sloughing and inflammation of the bladder lining, leading to bleeding and hemorrhage. This is most common when urine output is low because higher concentrations of acrolein come into contact with the bladder urothelium for longer periods of time. Radiation treatment directly damages the protective glycosaminoglycan layer of the bladder epithelium.

PREVENTION

KEY CONCEPT The use of effective prevention strategies can decrease the incidence of hemorrhagic cystitis to fewer than 5% in patients receiving cyclophosphamide or ifosfamide. Three methods are used to reduce the risk: administration of

Clinical Presentation and Diagnosis of Hemorrhagic Cystitis

General

- Presentation may be mild (microscopic hematuria) or severe (massive hemorrhage) and develops during or shortly after chemotherapy infusion.
- Presentation may be delayed when associated with pelvic radiation.

Signs and Symptoms

- Suprapubic pain and cramping, urinary urgency and frequency, dysuria and burning, and hematuria
- Urinary retention leading to hydronephrosis and renal failure may occur if large blood clots obstruct the ureters or bladder outlet

Laboratory Tests

- Urine dipsticks for blood
- Urinalysis reveals more than three RBCs per high-power field: microscopic hematuria
- CBC with differential, prothrombin time or international normalized ratio, activated partial thromboplastin time, blood urea nitrogen, creatinine

mesna (2-mercaptoethane sulfonate), hyperhydration, and bladder irrigation with catheterization. Mesna is the primary method used with ifosfamide; all three strategies are used with cyclophosphamide.

Mesna is a thiol compound that is rapidly oxidized in the bloodstream after administration to dimesna, which is inactive. However, after being filtered through the kidneys, dimesna is reduced back to mesna, which binds to acrolein, leading to its inactivation and excretion. ASCO has published evidence-based guidelines for the dosing and administration of mesna (Table 99–12).[41] The dose of oral mesna must be double the IV dose because of its oral bioavailability between 40% and 50%. Because the half-life of mesna (~1.2 hours) is much shorter than that of ifosfamide or cyclophosphamide, prolonged administration of mesna beyond the end of the chemotherapy infusion is critical (Figure 99–2). Patients should receive at least 2 L of IV fluids beginning 12 to 24 hours before and ending 24 to 48 hours after the last dose of chemotherapy.[41]

Hyperhydration with normal saline at 3 L/m^2/day with IV furosemide to maintain urine output greater than 100 mL/hour has also been used with cyclophosphamide. Continuous bladder irrigation by catheterization uses normal saline at 250 to 1000 mL/hour to flush acrolein from the bladder. Mesna is equivalent to both strategies in patients receiving high-dose cyclophosphamide and avoids the discomfort and infection risk with catheterization and the intensity of hyperhydration. Thus, mesna is the preventative method of choice.[41]

TREATMENT

Desired Outcomes

If hemorrhagic cystitis occurs, the goals of treatment are to decrease exposure to the offending etiology, establish and maintain urine outflow, avoid obstruction and renal compromise, and maintain blood and plasma volume. Restoration of normal bladder function is the ultimate goal following acute treatment.

General Approach to Treatment

The treatment of hemorrhagic cystitis first involves discontinuation of the offending agent. Agents such as anticoagulants and

Table 99–12

ASCO Guidelines for the Use of Mesna with Ifosfamide and High-Dose Cyclophosphamide

Chemotherapy Schedule	Dosing Schedule for Mesna	Comments
Low-dose ifosfamide < 2 g/m^2/day	Oral: 100% of total daily dose of ifosfamide given 20% IV: 15 minutes before and 40% po 2 and 6 hours after start of ifosfamide	Available in 400-mg tablets Peak urinary thiol concentrations with oral mesna is at 3 hours If patient vomits within 2 hours of administration, repeat dose po or IV
Standard-dose ifosfamide equal to 2.5 g/m^2/day	Bolus: 60% of total daily dose of ifosfamide given IV in 20% increments 15 minutes before and 4 and 8 hours after start of ifosfamide Infusion: 60% of total daily dose of ifosfamide given 20% IV 15 minutes before and 40% by continuous infusion during and for 12–24 hours after end of ifosfamide	Peak urinary thiol concentrations with IV mesna is at 1 hour Compatible with ifosfamide and cyclophosphamide by Y-site administration or when admixed in the same bag
High-dose ifosfamide > 2.5 g/m^2/day	Lack of evidence for dosing, but higher doses for longer duration recommended based on longer half-life of ifosfamide at high doses	
Standard-dose cyclophosphamide	Use of mesna is not routinely necessary	
High-dose cyclophosphamide (BMT)	Bolus: 40% of cyclophosphamide dose given IV at hours 0, 3, 6, and 9 after cyclophosphamide Infusion: 100% of cyclophosphamide dose given by continuous infusion until 24 hours after cyclophosphamide	Should be combined with saline diuresis (1.5 L/m^2/day of normal saline)

inhibitors of platelet function should also be discontinued. Intravenous fluids should be aggressively administered to irrigate the bladder.[41,42] Blood and platelet transfusions may be necessary to maintain normal hematologic values. Pain should be managed with opioid analgesics. Local intravesicular therapies may be necessary if hematuria does not resolve (Figure 99–3).

▶ *Nonpharmacologic Therapy*

A large-diameter, multihole urethral catheter should be inserted to facilitate saline lavage and evacuation of blood clots. Surgical removal of blood clots under anesthesia may be required if saline lavage is ineffective. Active bleeding from isolated areas may be cauterized with an electrode or laser. In severe cases that are unresponsive to local or systemic pharmacologic intervention, urinary diversion with percutaneous nephrostomy or surgical removal of the bladder may be required.

▶ *Pharmacologic Therapy*

A number of local or systemic agents are used in the treatment of hemorrhagic cystitis.[42] Local (direct instillation into the bladder), one-time administration of hemostatic agents such as alum, prostaglandins, silver nitrate, and formalin may be used; however, general anesthesia is required, especially with formalin, because of pain. Aluminum toxicity has been noted with alum irrigation, particularly in children. Systemic agents, including estrogens, vasopressin, aminocaproic acid, and hyperbaric oxygen (HBO), may be used in patients who are refractory to local therapy, although they introduce the risk of systemic side effects. HBO is particularly useful for radiation- and cyclophosphamide-induced cystitis. These agents should be continued until bleeding stops.

Antispasmodic agents such as oxybutynin 5 mg by mouth two to three times daily may be used for bladder spasms. In patients with refractory pain, opioid analgesics should be titrated to adequate pain control. In very severe cases refractory to medical therapy, surgical procedures may be warranted.

OUTCOME EVALUATION

The goal of treatment is resolution of bladder symptoms and appropriate pain management.

Monitor the patient for resolution of hematuria after each successive therapeutic intervention. The frequency of monitoring is based on the severity of hemorrhaging. Monitor urinary output and serum chemistries (including sodium, potassium, chloride, blood urea nitrogen [BUN], and serum creatinine) daily for renal dysfunction. Check the CBC at least daily to monitor hemoglobin and platelet count.

METABOLIC COMPLICATIONS: HYPERCALCEMIA OF MALIGNANCY

INTRODUCTION

Hypercalcemia is the most common metabolic abnormality experienced by patients with cancer. A small percentage of undiagnosed patients present with hypercalcemia. Once hypercalcemia occurs, it is associated with a very poor prognosis because of the frequent association with advanced or metastatic disease.[43]

EPIDEMIOLOGY AND ETIOLOGY

Hypercalcemia occurs in 10% to 30% of patients with cancer during the course of their disease. The most common tumor types associated with hypercalcemia are breast cancer; squamous cell carcinomas of the head, neck, and lung; and renal cancer. Hematologic malignancies such as multiple myeloma and, rarely, lymphomas are other underlying malignancies associated with hypercalcemia.

PATHOPHYSIOLOGY

Around 99% of calcium is contained in the bones; the other 1% resides in the extracellular fluid. Of this extracellular calcium, approximately 40% is bound to albumin, and the remainder is in

the ionized, physiologically active form. Normal calcium levels are maintained by three primary factors: parathyroid hormone (PTH), 1,25-dihydroxyvitamin D, and calcitonin. PTH increases renal tubular calcium resorption and promotes bone resorption. The active form of vitamin D, 1,25-dihydroxyvitamin D, regulates absorption of calcium from the GI tract. Calcitonin serves as an inhibitory factor by suppressing osteoclast activity and stimulating calcium deposition into the bones.[43]

The delicate balance maintained by these factors is altered in patients with cancer by two principal mechanisms: tumor production of humoral factors that alter calcium metabolism in the absence of bone metastasis (humoral hypercalcemia) and by local osteolytic activity from bone metastases. Humoral hypercalcemia causes around 80% of all hypercalcemia cases and is primarily mediated by systemic secretion of PTH-related protein (PTHrP). This protein mimics the action of endogenous PTH on bones. Local osteolytic activity causes 20% to 30% of hypercalcemia cases, although local osteolytic activity may also have a humoral component. Local production of various factors such as PTHrP, transforming growth factor-β, interleukin-1, and interleukin-6, and tumor necrosis factor-α promotes RANK ligand expression on osteoblasts. RANK ligand signaling to the RANK receptor on osteoclasts causes osteoclast maturation and activation, leading to bone resorption. Thus, these metastatic tumors perpetuate their own growth through this mechanism. Calcium is also released by the osteolytic activity, resulting in hypercalcemia. Of note, multiple myeloma, breast, and lung cancer patients tend to develop osteolytic lesions and are at increased risk for hypercalcemia, whereas prostate cancer patients tend to develop osteoblastic lesions and are more at risk for hypocalcemia. A third and less common mechanism is production of 1,25-dihydroxyvitamin D by tumor cells (usually lymphoma), which increases GI absorption of calcium and enhances osteoclastic bone resorption.

TREATMENT

Desired Outcomes

KEY CONCEPT The primary goal of treatment for hypercalcemia is to control the underlying malignancy. Therapies directed at lowering the calcium level are temporary measures that are useful until anticancer therapy begins to work. The goals of calcium-lowering therapy are to (a) lower the corrected calcium to normal levels,

Clinical Presentation and Diagnosis of Hypercalcemia[43,44]

General

- Presence of symptoms depends not only on the calcium level but the rapidity of onset.
- Normal calcium level is 8.5 to 10.5 mg/dL (2.13–2.63 mmol/L) (varies by laboratory).
- Serum calcium level *must* be corrected for albumin level using the following formula:

Corrected calcium (mg/dL) = Serum calcium + 0.8 (4 – Serum albumin) for serum calcium expressed in mg/dL and albumin in g/dL.

or

Corrected calcium (mmol/L) = Serum calcium + 0.02 (40 – serum albumin) for serum calcium expressed in mmol/L and albumin in g/L.

Signs and Symptoms

- Five primary organ systems may be affected:
  - GI: lack of appetite, nausea, vomiting, constipation
  - Musculoskeletal: weakness, bone pain, fatigue, ataxia
  - CNS: confusion, headache, lethargy, seizures, coma
  - Genitourinary: polydipsia, polyuria, renal failure
  - Cardiac: Bradycardia, ECG abnormalities, arrhythmias

Laboratory Tests

- Elevated corrected serum calcium level (≥ 10.5 mg/dL [2.63 mmol/L]), low serum albumin, low to normal serum phosphate.
- Patient may have elevated blood urea nitrogen and serum creatinine.
- Elevated alkaline phosphatase may indicate bone destruction.
- ECG may indicate prolonged PR interval, shortened QT interval, widened T wave.

Other Diagnostic Tests

- Rule out other causes of hypercalcemia, including primary hyperparathyroidism, hyperthyroidism, vitamin D intoxication, chronic renal failure.

(b) regain fluid and electrolyte balance, (c) relieve symptoms, and (d) prevent life-threatening complications.[43,44] Hypercalcemia is often indicative of a progressing cancer, with survival rates ranging from 2 months to 4.5 months.

General Approach to Treatment

Therapeutic options for the treatment of hypercalcemia should be directed toward the level of corrected serum calcium and the presence of symptoms (Figure 99–4). Hypercalcemia may

be classified as mild (corrected calcium equal to 10.5–11.9 mg/dL [2.63–2.98 mmol/L]), moderate (12–13.9 mg/dL [3.00–3.49 mmol/L]), and severe (more than 14 mg/dL [3.50 mmol/L] or more).[43,44] Adequate treatment of mild or asymptomatic hypercalcemia may be achieved on an outpatient basis with nonpharmacologic measures. Moderate to severe or symptomatic hypercalcemia almost always requires pharmacologic intervention. Ultimately, effective treatment of the patient's underlying malignancy is the most important factor for the long-term prevention and management of hypercalcemia.[44]

▶ *Nonpharmacologic Therapy*

Calciuric therapy in the form of hydration is a key component in the treatment of hypercalcemia, regardless of severity or presence of symptoms. The goal is to achieve a goal urine output at 100 to 150 ml/hour. Mild or asymptomatic patients may be encouraged to increase their oral fluid intake (3–4 L/day). Patients with moderate to severe or symptomatic hypercalcemia should receive normal saline at 200 to 500 mL/hour according to their dehydration and cardiovascular status. Patients should be encouraged to ambulate as much as possible because immobility enhances bone resorption. Although calcium should be discontinued from parenteral feeding solutions, oral calcium supplementation minimally contributes to hypercalcemia unless it is mediated by vitamin D. In these cases, oral calcium should be discontinued. Finally, agents that may contribute to hypercalcemia (thiazide diuretics, vitamin D, lithium) or decrease renal function (NSAIDs) should be discontinued. Dialysis may be used in refractory cases or patients who cannot tolerate aggressive saline hydration.

▶ *Pharmacologic Therapy*

Multiple pharmacologic interventions are available for the treatment of hypercalcemia (Table 99–13). Intravenous furosemide dosed at 20 to 40 mg/day may be added to hydration after rehydration has been achieved to avoid fluid overload and enhance renal excretion of calcium. Although effective in relieving symptoms, hydration and diuretics are temporary measures that are useful until the onset of antiresorptive therapy; thus, hydration and antiresorptive therapy should be initiated simultaneously.

Table 99–13

Treatment Options for Hypercalcemia of Malignancy

	Agent	Dosage	Onset	Duration of Action	Reduction in Serum Calcium Concentration	Comments
Calciuric therapy	IV normal saline	200–500 mL/ hour 2	24–48 hours	2–3 days	0.5–2 mg/dL (0.13–0.50 mmol/L)	Avoid fluid overload, monitor electrolytes
	Furosemide	0–40 mg IV	4 hours	2–3 days		Monitor for hypokalemia, dehydration
Antiresorptive therapy	Pamidronate	60–90 mg IV over 2–24 hours[a]	24–72 hours	3–4 weeks	> 1 mg/dL (0.25 mmol/L)	Nadir not seen until after 4–7 days; may cause fever, renal dysfunction
	Zoledronic acid	4 mg IV over 15 minutes	24–48 hours	4+ weeks	> 1 mg/dL (0.25 mmol/L)	Monitoring for acute tubular necrosis and severe acute renal toxicity (rare), osteonecrosis of the jaw if used long term.
	Corticosteroids	Prednisone (or equivalent) 50–100 mg/day	5–7 days	3–4 days	0.5–3 mg/dL (0.13–0.75 mmol/L)	Monitor for hyperglycemia, insomnia, immunosuppression
	Calcitonin	4–8 IU/kg SC or IM every 6–12 hours	2–4 hours	1–3 days	2–3 mg/dL (0.50–0.75 mmol/L)	Salmon-derived formulation preferred; 1-unit test dose recommended; can be given in renal failure; may cause flushing, nausea
	Gallium nitrate	100–200 mg/m^2 CIV daily for 5 days	24–48 hours 48–96 hours	Up to 104 days	> 1 mg/dL (0.25 mmol/L)	Do not administer if creatinine > 2.5 mg/dL (221 μmol/L); may cause renal failure
	Denosumab	120 mg SQ days 1, 8, and 15, then day 1 only every 4 weeks				Not renally cleared, may be used in patients with renal dysfunction, but reduce dose as increased risk of hypocalcemia in renally impaired, osteonecrosis of the jaw if used long term.

[a] 60 mg of pamidronate may be used in smaller patients or in patients with mild hypercalcemia or renal dysfunction. May use longer infusion time in patients with renal dysfunction.

CIV, continuous intravenous infusion; IM, intramuscular; IV, intravenous; SC, subcutaneous.

Data from Body JJ, Niepal D, Tonini G. Hypercalcemia and hypocalcemia: finding the balance. Support Care Cancer. 2017;25(95):1639–1649; Zagzag J, Hu MI, Fisher SA, Perrier ND. Hypercalcemia and cancer: Differential diagnosis and treatment. CA Cancer J Clin. 2018; 68(5):377–386.

The antiresorptive therapy of choice for hypercalcemia of malignancy is a bisphosphonate. Because of poor oral bioavailability, only IV agents should be used. Pamidronate and zoledronic acid are most commonly used and potent inhibitors of osteoclast activity.[41] The bisphosphonates should be administered at diagnosis of hypercalcemia because of their delayed onset of action.

Calcitonin is the drug of choice in cases of emergent hypercalcemia (patients with life-threatening electrocardiographic [ECG] changes, arrhythmias, or central nervous system [CNS] effects) because of its rapid onset of action. Calcitonin inhibits osteoclast activity and decreases renal tubular calcium resorption. However, calcitonin does not yield sustained effects and bisphosphonates are usually necessary as well. Corticosteroids are useful in patients with steroid-responsive malignancies, such as lymphomas or multiple myeloma, and may delay tachyphylaxis to calcitonin. Gallium nitrate is another treatment option, although the 5-day administration regimen and risk of nephrotoxicity limit its use. Denosumab, a RANKL inhibitor, is FDA-approved for hypercalcemia refractory to bisphosphonates at 120 mg subcutaneously days 1, 8, and 15, then monthly thereafter.[44]

OUTCOME EVALUATION

The long-term success of therapy for hypercalcemia is determined primarily by the success of treatment of the underlying malignancy. The goal of treatment is to reduce serum calcium levels to normal range and relieve patient symptoms and life-threatening complications if present.

METABOLIC COMPLICATIONS: TLS

INTRODUCTION

Although not as common as hypercalcemia, TLS may cause significant morbidity and mortality if adequate prophylaxis and treatment are not instituted. TLS is the result of rapid destruction of malignant cells with subsequent release of intracellular contents into the circulation.

EPIDEMIOLOGY AND ETIOLOGY

The overall incidence of TLS is unknown, but has been linked to a number of patient- and tumor-related risk factors (Table 99–14). TLS typically occurs in malignancies with high tumor burden or high proliferative rates, such as hematological malignancies including aggressive leukemias and lymphomas. TLS is typically induced by cancer treatment modalities, including chemotherapy, hormonal therapy, radiation, biologic therapy, or corticosteroids, although some patients may present spontaneously before treatment.[45]

Table 99–14

Risk Factors for Tumor Lysis Syndrome

Characteristic	Risk Factor
Cancer type	Burkitt lymphoma Lymphoblastic lymphoma Diffuse large-cell lymphoma ALL Solid tumors with high proliferative rates and rapid response to therapy
Tumor burden/extent of disease	Bulky disease (10 cm) Elevated LDH (2ULN) Elevated WBC (25,000/L)
Patient's organ function	Preexisting renal failure: oliguria
Baseline uric acid	Baseline serum/plasma uric acid: 450 mol/L (7.5 mg/dL)

ALL, acute lymphoblastic leukemia; LDH, lactate dehydrogenase

Adopted from: Coiffer B, Altman A, Pui CH, Younes A, Cairo MS. Guidelines for the management of pediatric and adult tumor lysis syndrome: an evidence-based review. J Clin Oncol. 2008; 2767–2778.

PATHOPHYSIOLOGY

Patients with TLS experience a wide range of metabolic abnormalities. The massive cell lysis that occurs leads to the release of intracellular electrolytes, resulting in hyperuricemia, hyperkalemia, and hyperphosphatemia. High concentrations of phosphate can bind to calcium, leading to hypocalcemia and calcium phosphate precipitation in the renal tubule. Purine nucleic acids are also released, which are subsequently metabolized to uric acid through multiple enzyme-mediated steps (Figure 99–5). Uric acid is poorly soluble at urinary acidic pH, leading to crystallization in the renal tubule. The precipitation of uric acid and calcium

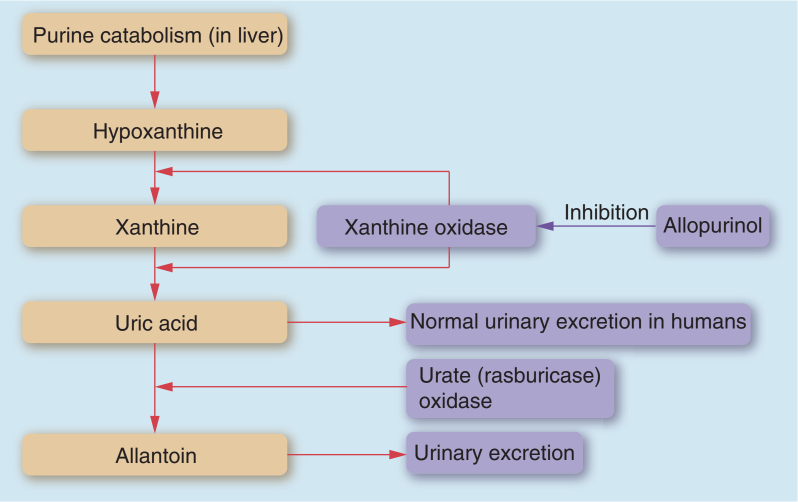

FIGURE 99–5. The role of allopurinol and rasburicase in the enzymatic degradation of purine nucleic acids.

Clinical Presentation and Diagnosis of TLS[45]

General

- Patients present primarily with laboratory abnormalities.
- Normal uric acid is equal to 2 to 8 mg/dL (119–476 μmol/L).
- Most often occurs within 12 to 72 hours of initiation of cytotoxic therapy.

Signs and Symptoms

- Most patients are asymptomatic; some patients may develop edema, fluid overload, and oliguria, which may progress to anuria with acute renal failure.
- Some patients with hyperuricemia may have nausea, vomiting, and lethargy.
- Hyperkalemia: lethargy, muscle weakness, **paresthesia**, ECG changes, bradycardia
- Hypocalcemia: muscle cramps, **tetany**, irritability, paresthesias, arrhythmias

Laboratory Tests (Adults)

- Serum uric acid level greater than 7.5 mg/dL (450 μmol/L)
- Serum potassium greater than 6 mEq/L (6 mmol/L)
- Serum phosphorus greater than 6.5 mg/dL (2.1 mmol/L)
- Serum calcium less than 7 mg/dL (1.75 mmol/L)
- Elevated blood urea nitrogen and creatinine once renal dysfunction develops

or

- A change of greater than 25% from baseline in the above laboratory values

phosphate leads to metabolic acidosis, facilitating further uric acid crystallization. Acute renal failure may be the end result.[45]

TREATMENT

Desired Outcomes

KEY CONCEPT The primary goals of management of TLS are (a) prevention of renal failure and (b) prevention of electrolyte imbalances. Thus, the best treatment for TLS is prophylaxis to enable delivery of cytotoxic therapy for the underlying malignancy. For patients who present with or develop TLS despite prophylaxis, treatment goals include (a) decreasing uric acid levels, (b) correcting electrolyte imbalances, and (c) preventing compromised renal function. These goals should be achieved in a cost-effective manner.

General Approach to Treatment

Prevention of TLS is generally achieved by increasing the urine output and preventing accumulation of uric acid. Prophylactic strategies should begin immediately upon presentation, preferably 48 hours prior to cytotoxic therapy. Treatment modalities for established TLS primarily increase uric acid solubility, maintain electrolyte balance, and support renal output.[45]

▶ *Nonpharmacologic Therapy*

Vigorous IV hydration with dextrose 5% in water with half normal saline at 3 L/m^2/day to maintain a urine output greater than or equal to 100 mL/m^2/hour is necessary unless the patient presents with acute renal dysfunction. Alkalinization of the urine to a pH greater than or equal to 7.0 with 50 to 100 mEq/L (50–100 mmol/L) of sodium bicarbonate has been used to promote uric acid solubility for excretion. This measure is controversial because xanthine and hypoxanthine are less soluble at alkaline pH, potentially leading to crystallization, especially during and after allopurinol therapy (see Figure 99–5).[45] Medications that increase serum potassium (angiotensin-converting enzyme inhibitors, spironolactone) or block tubular resorption of uric acid (probenecid, thiazides) should be discontinued. Nephrotoxic agents such as amphotericin B or aminoglycosides should also be avoided. Hemodialysis may be required in patients who develop anuria or uncontrolled hyperkalemia, hyperphosphatemia, hypocalcemia, acidosis, or volume overload.

▶ *Pharmacologic Therapy*

Allopurinol is a xanthine oxidase inhibitor that is used for prevention only because it has no effect on preexisting elevated uric acid. Studies have also evaluated the role of febuxostat, a potent xanthine oxidase inhibitor which does not require renal adjustment, for prevention of TLS. Rasburicase is a recombinant form of urate oxidase that is useful for both prevention and treatment but is expensive (Figure 99–6, Table 99–15). Although the approved dose is 0.2 mg/kg/day for 5 days, recent studies using abbreviated courses (1–3 days) and/or lower doses (0.05–0.1 mg/kg/day) may be equally efficacious with significantly reduced cost.[41] Because uric acid levels generally fall within 4 hours of the first dose, one dose may be administered with frequent, serial monitoring of the uric acid level for repeat dosing if necessary (see Figure 99–6). Of note, rasburicase continues to break down uric acid in blood samples drawn from patients. This can be avoided by immediately placing the sample in an ice bath for processing to avoid falsely lowered uric acid levels.[45]

Electrolyte disturbances that develop in patients with TLS should be aggressively managed to avoid renal failure and cardiac sequelae. One exception pertains to the use of IV calcium for hypocalcemia. Adding calcium may cause further calcium phosphate precipitation in the presence of hyperphosphatemia and should be used cautiously.

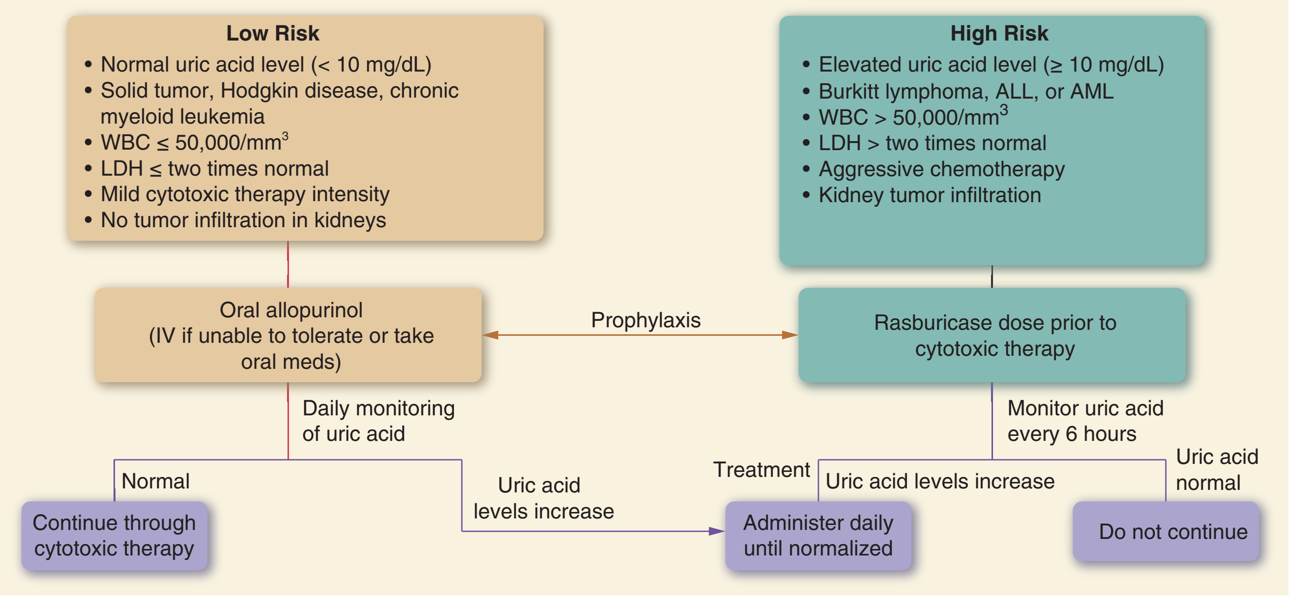
OUTCOME EVALUATION

The most successful outcome in TLS is prevention. If the condition is not able to be prevented, the goal of treating established TLS is to avoid renal failure and quickly return electrolytes to normal.

IMMUNOTHERAPY-RELATED TOXICITES

INTRODUCTION

Management of cancer has evolved over the past decade with the introduction of immunotherapy such as chimeric antigen receptor (CAR) T-cell therapies and immune checkpoint inhibitors (ICIs) into clinical practice. However, with the increased usage of immunotherapies for treatment of cancer, a myriad of toxicities associated with immunotherapy have also surfaced. Severe systemic inflammation is commonly observed with the use of CAR T-Cell therapies, known as cytokine release syndrome (CRS) in the literature, whereas toxicities associated with ICIs are commonly termed as immune-related adverse events (irAEs).[46]



Low Risk
• Normal uric acid level (< 10 mg/dL)
• Solid tumor, Hodgkin disease, chronic myeloid leukemia
• WBC ≤ 50,000/mm³
• LDH ≤ two times normal
• Mild cytotoxic therapy intensity
• No tumor infiltration in kidneys
High Risk
• Elevated uric acid level (≥ 10 mg/dL)
• Burkitt lymphoma, ALL, or AML
• WBC > 50,000/mm³
• LDH > two times normal
• Aggressive chemotherapy
• Kidney tumor infiltration
Oral allopurinol (IV if unable to tolerate or take oral meds)
Prophylaxis
Rasburicase dose prior to cytotoxic therapy
Daily monitoring of uric acid
Monitor uric acid every 6 hours
Normal
Continue through cytotoxic therapy
Uric acid levels increase
Treatment
Uric acid levels increase
Uric acid normal
Administer daily until normalized
Do not continue

FIGURE 99–6. Prophylaxis and treatment of hyperuricemia associated with tumor lysis syndrome. (ALL, acute lymphoblastic leukemia; AML, acute myelogenous leukemia; IV, intravenous; LDH, lactate dehydrogenase; WBC, white blood cell.)

EPIDEMIOLOGY AND ETIOLOGY

The reported incidence of any grade irAEs associated with ICI monotherapy ranges widely across agents and trials, from approximately 15% to 90%. Severe irAEs requiring immunosuppression and hold or therapy discontinuation are estimated between 0.5% and 13%. On the other hand, rates of severe CRS between the two CD19-targeted CAR T-cell therapies (axicabtagene ciloleucel and tisagenlecleucel) are consistently high, with severe CRS ranging between 13% and 23%.[46]

PATHOPHYSIOLOGY

As immunotherapy works by activating the immune response, raised levels of cytokines as a downstream effect of T-cell activation can trigger systemic inflammation. The development of CRS occurs following an increase of inflammatory cytokines, such as IL-6, which are released after the activation and destruction of various blood cells including marcrophages, lymphocytes, and monocytes. Immune checkpoint antibodies can bind to targets that are expressed in normal organs, which could lead to complement-mediated inflammation. Furthermore, immunotherapy can also lead to an elevation of autoreactive antibiodies, triggering inflammatory responses.

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentations of toxicities associated with immunotherapy are phenotypically different from those observed with traditional anticancer therapies such as chemotherapy. Acute inflammation associated with CRS, within the first 2 to 3 days of infusion, are often observed with CAR T-cell therapies, which often manifest as high fevers, hypotension, hypoxia, and multiorgan damage. Neurologic toxicities can occur between in the median of 4 to 6 days after initiation of therapy.[47]

Table 99–15

Treatment Options for Tumor Lysis Syndrome

Drug	Dosing	Comments
Oral allopurinol (Zyloprim)	Adult: 600–800 mg/day in two to three divided doses Pediatric: 10 mg/kg/day or 200–300 mg/m^2/day	Adjust dose for renal impairment Avoid drug interactions (mercaptopurine) Monitor for skin rash Start 1–2 days prior to chemotherapy
IV allopurinol (Aloprim)	Adult: 200–400 mg/m^2/day Pediatric: 200 mg/m^2/day	As above Reserve for patients who cannot tolerate or take oral medications Maximum dose = 600 mg/day
Rasburicase (Elitek)	0.2 mg/kg/day for up to 5 days	Lower doses and abbreviated schedules may be used to decrease cost (0.05–0.1 mg/kg/day) May rarely cause nausea and vomiting Contraindicated in patients with G6PD deficiency → hemolytic anemia Rare cases of hypersensitivity and antibody formation

[a]Normalized for 70-kg patient or body surface area = 1.73 m^2; all costs are estimated and may vary.

AWP, average wholesale price; G6PD, glucose-6-phosphate dehydrogenase; po, oral.

From Wilson FP, Berns JS. Tumor lysis syndrome: new challenges and recent advances. Adv Chronic Kidney Dis. 2014;21(1):18–26.

Table 99–16

General Management of ICI-induced irAEs

Grade	Management Strategy
1 (mild)	ICI therapy should be continued with close monitoring, with the exception of some neurologic, hematologic, and cardiac toxicities. Corticosteroids are not usually required.
2 (moderate)	Hold ICI and consider resuming when symptoms and/or laboratory values revert to grade 1 or less. Low dose corticosteroids (0.5–1 mg/kg/day) should be considered.
3 (severe)	Hold ICI and initiate high-dose corticosteroids (prednisone 1–2 mg/kg/day or equivalent). Gradually taper corticosteroid dose over at least 4 to 6 weeks once symptoms improve to ≤grade 1.
4 (life-threatening)	Permanent discontinuation of ICI with the exception of endocrinopathies that have been controlled by hormone replacement. initiate high-dose corticosteroids (prednisone 1 to 2 mg/kg/day).

ICI = immune checkpoint inhibitor; irAEs = immune-related adverse events

From: Medina P, Jeffers KD, Trinh VA, Harvey RD. The Role of Pharmacists in Managing Adverse Events Related to Immune Checkpoint Inhibitor Therapy. J Pharm Pract 2020;33(3):338–349.

In contrast to CAR T-cell therapies and cytotoxic chemotherapy that often result in acute-onset adverse events, the onset of irAEs associated with ICI are generally slower in nature. Among all ICIs, cytotoxic T-lymphocyte-associated protein (CTLA)-4 inhibitors generally have higher rates and higher severity of irAEs than anti-programmed cell death 1 (PD-1)/programmed cell death ligand 1 (PD-L1) inhibitors, particularly in patients with baseline autoimmune conditions. Observed toxicities associated with ICI-based combination regimens are also more severe than that for ICI monotherapy. irAEs can essentially attack any organ systems causing toxicities. The most commonly observed toxicities include dermatological toxicity, gastrointestinal toxicity, endocrine toxicity, and pulmonary toxicity. There is also growing literature reporting toxicities related to the nervous and cardiovascular systems. Development of irAEs is unpredictable and does not appear to correlate with cumulative dose toxicity or anticancer efficacy.[46]

TREATMENT

Desired Outcomes

The goal is to reduce the prevent the onset and severity of immunotherapy-related toxicities, as these toxicities may affect patients' quality of life. In addition, it is important to ensure that the management of immunotherapy-related toxicities does not impact the efficacy of anticancer treatment.

General Approach to Treatment

Currently, a number of guidelines are available for the management of immunotherapy-related toxicities.[46,48,49] The general approach to management of ICI-induced iRAEs focuses on early recognition of symptoms and prompt intervention. Mild reactions of iRAEs often lead to temporarily withholding of immunotherapy, and severe iRAEs may require permanent discontinuation of the class of agent associated with the toxicity (Table 99–16).

On the other hand, the general approach to management of mild CRS is supportive in nature and consists of managing flu-like symptoms, headaches, fatigue, and myalgias. Severe CRS would require intensive care, incorporating rapid management of hypotension, hypoxia, and organ dysfunction with fluids, vasopressors, oxygen, and other supportive interventions.

▸ *Nonpharmacologic Therapy*

Due to the aggressive nature of CRS, CAR T-cell therapies are only available commercially at facilities certified through a Risk Evaluation and Mitigation Strategy (REMS) program. In patients receiving CAR T-cell therapies, aggressive preventive care and close monitoring must be undertaken before, during, and post CAR T-cell infusion. Precautions such as TLS precautions and baseline brain MRI should also be considered. Close monitoring of metabolic panel, coagulation profile, complete blood count, CRP, and ferritin should be routinely performed. Assessment of CRS and neurological function should be done at least twice daily when patients are at risk. Lastly, aggressive cardiac monitoring under telemetric conditions should be performed in patients presenting with grade 2 CRS. Similar to CAR T-cell therapies, recipient of ICI should receive comprehensive assessment prior to therapy include neurological examination, laboratory tests, and thyroid function testing.

▸ *Pharmacologic Therapy*

KEY CONCEPT Corticosteroids are the mainstay of treatment for more severe irAEs and CRS. Early administration of steroids (within 5 days from the onset of symptoms) has been associated with more rapid resolution of diarrhea and colitis compared with delayed steroid initiation. Depending on the type and severity of the irAEs, prednisone doses ranging from 0.5 to 2 mg/kg/day have been used. Generally, a minimum tapering duration of 4 to 6 weeks is recommended, since irAE recurrence and/or worsening

Patient Encounter 3: Immune-related adverse events

Your patient is a 48-year-old woman with metastatic melanoma began combination ipilimumab and nivolumab with normal labs and no significant adverse events after her first three doses of treatment. he is receiving her fourth dose today. She stated that she feels unwell with fevers, and her liver function tests (LFTs) revealed transaminitis (AST = 201, ALT = 237), fever, and an elevated alkaline phosphatase. Bilirubin was within normal limits. The oncologist suspects that she is manifesting immune-related hepatitis.

What is the severity of this patient's immune-related hepatitis?

How would you manage this patient at this time?

Patient Care Process

Collect Information:

- Review patient history of chemotherapy regimens and concurrent medications.
- Determine patient allergies, especially to antibiotics, antifungals, and antivirals.
- Evaluate risk of chemotherapy complications using appropriate NCCN practice guideline if available.
- Evaluate patient-specific risk factors.
- Review laboratory values, including WBC, electrolytes, hepatic and renal function, performance status, and vital signs.

Assess the Information:

- Determine complications (nausea, vomiting, febrile neutropenia, etc) to previous cycles of chemotherapy and risk with current cycle.
- Assess individual and treatment-related risk factors for chemotherapy complications.
- Determine insurance coverage for supportive care interventions, availability of appropriate storage conditions.

Develop a Care Plan:

- Communicate treatment goals of symptomatic management to the patient.
- Provide patient with education regarding appropriate use of supportive therapies and potential adverse effects.
- Educate patient about nonpharmacologic interventions to manage chemotherapy complications.
- Counsel patients regarding risk factors, symptoms to call their healthcare providers, and symptoms requiring a visit to the emergency room.

Implement the Care Plan:

- Initiate patient-specific supportive care therapy for managing chemotherapy complications.
- Coordinate follow-up with interprofessional team.

Follow-up: Monitor and Evaluate:

- Review laboratory values, including WBC, electrolytes, hepatic and renal function, performance status, and vital signs.
- Determine efficacy and adverse effects of supportive cancer intervention and determine if modifications in the treatment plan are required.
- Assess the patient for any new signs or symptoms of chemotherapy complications. Evaluate the patient for adverse drug reactions, drug allergies, and interactions. Have all medications been dose adjusted for renal or hepatic dysfunction?

may occur with rapid steroid taper.[48] For patients with severe irAEs that are not responsive to steroids within 48 to 72 hours, additional immunosuppression with another immunomodulator may be warranted.

In the management of CRS associated with CAR T-cell therapies, dexamethasone at 10 mg every 6 hours should be considered in patients who do not respond to anti-IL-6 therapy.[46] Antifungal prophylaxis should be considered in patients receiving corticosteroids for management of CRS. With the approval of tisagenlecleucel, tocilizumab was also FDA approved for the management of CRS. Tocilizumab is a humanized monoclonal antibody that is an IL-6 receptor antagonist. Traditionally, it has been used in the management of rheumatologic disorders but has also demonstrated efficacy in decreasing CRS-related symptoms after administration of CAR T cells.

In settings where immunotherapy-related toxicities are corticosteroid-refractory, a number of immunomodulators such as infliximab, vedolizumab, mycophenolate mofetil, cyclosporine, and intravenous immunoglobulin have been used in clinical practice. The use of immunosuppressants should be tailored carefully to prevent their potential on reducing antitumor efficacy. A number of retrospective studies have shown that immunosuppressive regimens administered in the setting of irAEs did not appear to compromise the outcomes of ICI therapies; however, it is still prudent to minimize the potential of systemic immunosuppression.

OUTCOME EVALUATION

The long-term success of therapy for management of immunotherapy related toxicities is determined primarily by the success of continuing immunotherapy without compromising efficacy.

Abbreviations Introduced in This Chapter

ANC	Absolute neutrophil count
AWP	Average wholesale price
BMT	Bone marrow transplantation
BUN	Blood urea nitrogen
CIV	Continuous intravenous infusion
CSF	Colony-stimulating factor
G6PD	Glucose-6-phosphate dehydrogenase
ICP	Intracranial pressure
IV	Intravenous
LDH	Lactate dehydrogenase
NSAID	Nonsteroidal anti-inflammatory drug
NSCLC	Non–small cell lung cancer
PCP	*Pneumocystis jiroveci* pneumonitis (formerly *Pneumocystis carinii*)
PTHrP	Parathyroid hormone–related protein
SCLC	Small cell lung cancer
SVCS	Superior vena cava syndrome

Parenteral Nutrition

Melissa R. Pleva and Michael D. Kraft

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. List appropriate indications for parenteral nutrition (PN) in adult patients.
2. Describe the components of PN and their role in nutrition support therapy.
3. List key elements of nutrition assessment and factors considered in assessing an adult patient's nutritional status and nutritional requirements.
4. List important recommendations to improve PN safety.
5. Explain important pharmaceutical and compounding concerns with PN admixtures.
6. Develop a plan to design, initiate, and adjust a PN formulation for an adult patient based on patient-specific factors.
7. Describe the etiology and risk factors for PN macronutrient-associated complications in adult patients receiving PN.
8. Describe the etiology and risk factors for refeeding syndrome, as well as measures to prevent refeeding syndrome.
9. Design a plan to assess the efficacy and monitor for safety, as well as fluid, electrolyte, vitamin, and trace element abnormalities in adult patients receiving PN.

INTRODUCTION

Malnutrition in hospitalized patients is associated with significant complications (eg, increased infection risk, poor wound healing, prolonged hospital stays, increased mortality), especially in surgical and critically ill patients.[1] Maintaining adequate nutritional status, especially during periods of illness and metabolic stress, is an essential part of patient care. *Nutrition support therapy* refers to the administration of nutrients via the oral, enteral, or parenteral route for therapeutic purposes.[1] **KEY CONCEPT** Parenteral nutrition (PN), also called total parenteral nutrition (TPN), is the intravenous (IV) administration of fluids, macronutrients, electrolytes, vitamins, and trace elements for the purpose of weight maintenance or gain, to preserve or replete lean body mass and visceral proteins, and to support anabolism and nitrogen balance when the oral or enteral route is not feasible or adequate. PN is a potentially lifesaving therapy in patients with intestinal failure but can be associated with significant or life-threatening complications.

Desired Outcomes and Goals

The goals of nutrition support therapy include:

- Correction or avoidance of nutritional deficiencies
- Weight maintenance (or weight gain in malnourished patients and growing children)
- Preservation or repletion of lean body mass and visceral proteins
- Support of anabolism and nitrogen balance and improvement of healing
- Correction or avoidance of fluid, electrolyte, vitamin, and trace element abnormalities
- Improved clinical outcomes

Indications for PN Therapy

PN can be a lifesaving therapy when indicated, but the oral or enteral route is preferred when providing nutrition support therapy. Compared with PN, enteral nutrition is associated with a lower risk of hyperglycemia and fewer infectious complications (eg, pneumonia, intra-abdominal abscess, catheter-related infections).[1-3] However, if used appropriately, PN can be safe and effective and can improve nutrient delivery. Indications for PN are listed in Table 100–1.[4] PN should be reserved for patients with altered intestinal function or absorption or when the gastrointestinal (GI) tract cannot be used. The anticipated duration of adequate PN therapy should be at least 5 to 7 days because shorter durations are unlikely to have a beneficial effect on a patient's clinical and nutritional outcomes.[1,2]

PN COMPONENTS

PN should provide a *balanced* nutrition formula, including macronutrients, micronutrients, fluids, and electrolytes. Macronutrients, including amino acids, dextrose, and injectable lipid emulsions (ILE; also known as IV lipid emulsion or IV fat emulsion), are important sources of structural and energy-yielding substrates. In a balanced PN formulation for adult patients, total daily calories are typically provided as 10% to 20% from amino acids, 50% to 60% from dextrose, and 15% to 30% from ILE. Amino acids may provide more than 20% of the total daily calories in

Table 100–1

Indications for Parenteral Nutrition in Adults[4]

- Bowel obstruction
  - Physical or mechanical (eg, tumor compressing intestinal lumen)
  - Functional (eg, ileus, colonic pseudo-obstruction)
- Major small bowel resection (eg, short bowel syndrome)
  - Adult patients with < 120 cm of small bowel distal to the ligament of Treitz without a colon
  - Adult patients with < 60 cm of small bowel if the colon is intact
- Ischemic bowel
- Impaired absorption (eg, complication of bariatric surgery, severe intractable vomiting, or diarrhea)
- High output intestinal fistulas if EN cannot be provided above or below the fistula
- Severe pancreatitis—if patients have failed EN beyond the ligament of Treitz or cannot receive EN (eg, because of intestinal obstruction)
- Inability to achieve or maintain enteral access
- Preoperative nutrition support in patients with moderate-to-severe malnutrition who cannot tolerate EN and in whom surgery can be delayed safely for at least 7 days

patients with conditions that increase protein requirements. See additional dosing details in each macronutrient section. Electrolytes and micronutrients, including vitamins and trace elements, are required to support essential biochemical reactions and maintain cellular homeostasis. Patients require individual adjustments of PN components based on their nutritional status, nutritional requirements, underlying disease state(s), degree of metabolic stress, clinical status, and organ functions.

Macronutrients

▶ *Amino Acids*

Amino acids, the building blocks of proteins, are an essential component of PN admixtures. **KEY CONCEPT** Amino acids are provided to preserve or replete lean body mass and visceral proteins, to promote protein anabolism and wound healing. Amino acids provide 4 kcal/g (17 kJ/g) of energy.

Parenteral crystalline amino acid solutions are supplied by various manufacturers in various concentrations, with a 10% or 15% solution used commonly in PN compounding. Different formulations are tailored for specific age groups and disease states. Formulations for patients with hepatic encephalopathy contain

Patient Encounter, Part 1

DB is a 47-year-old man with a history of depression and Crohn disease, status post small bowel resection. He was admitted approximately 2 weeks ago with signs and symptoms consistent with a bowel obstruction. He was taken to the OR for an exploratory laparotomy and found with multiple adhesions causing small bowel obstructions in two locations. He underwent an additional small bowel resection (jejunum) and extensive lysis of adhesions and was discharged 8 days ago. DB is readmitted with foul-smelling drainage from his surgical incision × 2 days along with nausea, decreased appetite, and decreased oral intake (~30% of estimated energy requirements) for the past 2 to 3 days. Since his diagnosis of Crohn disease, he has had intermittent weight loss, poor oral intake, and malnutrition. Most recently, he reports an unintentional weight loss of about 16 lb (7.3 kg) over the past 4 to 5 weeks.

Past Medical History

Depression × 10 years

Crohn disease diagnosed 20 years ago, status post small bowel resections 2 years ago and 8 days ago

Intermittent malnutrition since diagnosis of Crohn disease

Past Surgical History

Small bowel resection 2 years ago

Exploratory laparotomy with small bowel resection and lysis of adhesions due to small bowel obstruction (> 100 cm of small intestine remaining, ileocecal valve intact, all the colon remaining)

Family History

Mother and father: Hypertension, hyperlipidemia

Grandmother: Chronic constipation, depression

Social History

20 pack-year smoking history, quit 2 years ago; patient reports only occasional alcohol; no recreational drugs

Medications Prior to Admission

Sertraline 50 mg PO daily

Docusate 100 mg PO twice daily

Allergies

NKDA

Physical Examination

Height, 178 cm (~5 ft, 10 in); actual body weight, 72 kg (158 lb); ideal body weight, 75 kg (165 lb); temperature 37.2°C (99.0°F); heart rate, 75 beats/min; blood pressure, 116/69 mm Hg; respiratory rate, 14 breaths/min; alert and oriented × 3; mucous membranes and skin appear cool and dry; lungs clear

Abdomen: Soft, tender around incision, faint bowel sounds, drainage of apparent enteric contents from surgical incision

Physical examination otherwise unremarkable.

Diagnoses

Likely enterocutaneous fistula, probably from small bowel/jejunum (most recent surgery/small bowel resection), mild dehydration, and malnutrition

Plan

The patient was admitted to the hospital (non-ICU) for evaluation of a possible enterocutaneous fistula. The team performed a fistulogram and confirmed presence of an enterocutaneous fistula apparently originating in the proximal- to mid-jejunum. Given the patient's recent surgery, surgical intervention was deemed to not be an appropriate option at this time. A drain was placed into the fistula to control drainage and quantify output; the fistula drained ~ 600 mL in the first 24 hours. Against medical orders, the patient drank approximately 1 L of water, and the following day his fistula drained approximately 1500 mL of fluid. It is now hospital day #2.

Is PN therapy indicated in this patient? Why or why not?

higher amounts of branched-chain and lower amounts of aromatic amino acids. These specialized formulations have not been clearly shown to improve patient outcomes and are not routinely used in clinical practice. Crystalline amino acid solutions have an acidic pH (pH ≈ 5–7) and may contain inherent electrolytes (eg, sodium, potassium, acetate, phosphate).

▶ *Dextrose*

KEY CONCEPT Dextrose (D-glucose) is the major energy source in PN, and it is vital for cellular metabolism, body protein preservation, and cellular growth. The central nervous system, red blood cells, and the renal medulla depend primarily on dextrose as a source of energy.

Typically, a 70% (70 g/100 mL) parenteral dextrose (hydrous dextrose) stock solution is used in PN compounding. Hydrous dextrose provides 3.4 kcal/g (14.2 kJ/g). A dextrose infusion rate of 2 mg/kg/min in adult patients is typically sufficient to suppress gluconeogenesis and spare proteins from being used for energy.[5] Dextrose infusion rate in hospitalized adult patients should not exceed 4 to 5 mg/kg/min when PN is infused over 24 hours.[6] Use adjusted body weight (AdjBW; see Assessment section for calculation), rather than actual weight, in obese patients when calculating the dextrose infusion rate.

▶ *Lipid Injectable Emulsions*

KEY CONCEPT Injectable lipid emulsions (ILE) are provided to prevent or treat essential fatty acid deficiency (EFAD) and as an energy source. ILE particles consist of a triglyceride core surrounded by a layer of egg phospholipids (emulsifiers). These particles carry a negative charge on their surface that creates repulsive electrostatic forces between droplets and maintains the stability of the emulsion. Glycerol is added to adjust the tonicity, and water is the solvent. The negative charges on the surface of lipid particles can be disrupted by cations, especially divalent cations (eg, calcium, magnesium) and trivalent cations (eg, iron), and extreme pH changes, particularly acidic pH.[7] Creaming, coalescence, and oiling out are signs of a destabilized ILE. If there is any apparent disruption to ILE, it should *not* be infused into a patient.

ILEs differ in their concentration (10%, 20%, and 30%), caloric density by volume, natural source of fats/triglycerides, and ratio of phospholipids to triglycerides (PL:TG ratio). Table 100–2 shows a comparison of commercially available ILEs in the United States. Most standard ILEs in the United States contain long-chain triglycerides derived from soybean oil. Because of the addition of phospholipid emulsifiers and glycerol, the caloric density of ILEs by weight is 10 to 11 kcal/g (42–44 kJ/g; see Table 100–2; dietary fat is ~ 9 kcal/g [38 kJ/g]). Compared with the 10% ILE, 20% and 30% ILEs have a lower PL:TG ratio and lower phospholipid content, and this translates to better plasma clearance and lower rates of hypertriglyceridemia compared to the 10% ILE.[7] The 30% ILE is only approved by the Food and Drug Administration (FDA) for infusion in a total nutrient admixture (TNA) and should not be infused directly into patients nor via Y-site injection.

More recently the FDA approved three additional ILE products for use in the United States; two products for use in adult patients: SMOFLipid and Clinolipid and one product in pediatric patients: Omegaven (see Table 100–2). SMOFLipid is a combination of soybean oil, medium-chain triglycerides (MCTs), olive oil, and fish oil. Clinolipid is a mixture of refined olive and soybean oil. Omegaven is the first non–soybean oil–containing ILE available in the United States and contains only fish oil. All three alternative formulations result in a reduced amount of omega-6 fatty acids, and SMOFLipid and Omegaven have a higher concentration of omega-3 fatty acids. This may have a positive impact on inflammation and immune function, but significant data demonstrating improved clinical outcomes are lacking.[8] The optimal role of each of these ILE products in patient care is not yet known, but increasing evidence suggests a potential role for these alternative oil products in treatment of PN-associated liver disease (PNALD) (refer to "Complications of PN").[8]

The essential fatty acids that cannot be produced endogenously in humans are linoleic acid (C18:2 n-6) and α-linolenic acid (C18:3 n-3) (long-chain fatty acids). Arachidonic acid (C20:4 n-6) is also essential but can be synthesized in vivo from linoleic acid. Adult patients should receive a minimum of 2% to 4% of total daily calories as linoleic acid and 0.25% to 0.5% of total daily calories as α-linolenic acid to prevent EFAD.[7] This can be achieved by providing a minimum of ~ 100 g of soybean oil–based ILE per week (in a single dose or divided doses) for most adult patients. Higher total doses of new alternative ILE formulations may be required to prevent EFAD. The typical daily dose of ILE in adults is about 0.5 to 1 g/kg/day (or ~ 15%–30% of total daily calories). The maximum dose is 2.5 g/kg/day[7] or 60% of total daily calories, although soybean oil ILE doses this high are rarely used in practice and should be avoided to prevent complications.

Biochemical evidence of EFAD (eg, decreased serum linoleic acid, α-linolenic acid, and arachidonic acid concentrations; elevated mead acid concentrations; elevated triene-to-tetraene ratio) can develop in well-nourished adult patients within 2 to 4 weeks of receiving PN without ILE. Clinical manifestations (eg, dry skin, skin desquamation, hair loss, hepatomegaly, anemia, thrombocytopenia, poor wound healing) may begin to appear after an additional 1 to 2 weeks.[9]

Complications and safety concerns related to the administration of ILE include severe hypertriglyceridemia, infection, anaphylactic reactions, and infusion-related reactions. Patients with a history of hypertriglyceridemia, acute kidney injury, chronic kidney disease, hepatic dysfunction, severe metabolic stress, or pancreatitis (particularly if caused by hypertriglyceridemia) may have reduced lipid clearance and be at risk of developing hypertriglyceridemia.

ILEs support the growth of bacterial and fungal pathogens; bacterial growth is slower in total nutrient admixtures (TNAs) than in ILE alone due to the acidic pH of amino acid solutions and higher osmolarity of PN formulations.[10,11] Because of this, the Centers for Disease Control and Prevention (CDC) recommends that TNA infusions be completed within 24 hours of initiation. Recent guidelines suggest that ILE infusion should be completed ideally within 12 hours if administered from the original manufacturer container (within 24 hours if 12 hours not feasible for medical reasons), but completed within 12 hours if repackaged/transferred to another container and infused separately from a 2-in-1 PN admixture (although repackaging/transfer to another container was not recommended).[12]

Patients with an allergy to eggs (egg phospholipids), soybean (soybean oil), legumes (soybean oil), fish (fish oil), olives (olive oil), or other ingredients may develop cross-allergic reactions to ILE products.[13] Rarely, infusion-related adverse effects may occur with rapid infusion, including fever, chills, headache, palpitations, dyspnea, chest tightness, and nausea. Extending the ILE infusion time can minimize infusion-related adverse events and improves ILE clearance. The maximum recommended infusion rate of ILE is 0.11 g/kg/hour.[7]

Table 100–2

Comparison of Lipid Injectable Emulsion Products Approved in the United States

Brand Names	Intralipid			Nutrilipid	Liposyn III			SMOFLipid	Clinolipid	Omegaven[a]
Oil source(s)	Soybean oil			Soybean oil	Soybean oil			Soybean oil (30%) MCT (30%) Olive oil (25%) Fish oil (15%)	Olive oil (80%) Soybean oil (20%)	Fish oil
Concentration	10%	20%	30%[b]	20%	10%	20%	30%[b]	20%	20%	10%
Linoleic acid[c] (%)	44–62			48–58	54.5			14–25	13.8–22	1.5
α-Linolenic acid[d] (%)	4–11			4–11	8.3			1.5–3.5	0.5–4.2	1.1
Phospholipids (egg yolk) (%)	1.2			1.2	1.2	1.2	1.8	1.2	1.2	1.2
PL:TG ratio	0.12	0.06	0.04	0.06	0.12	0.06	0.06	0.06	0.06	0.12
Caloric density[e] (kcal/mL)	1.1	2	3	2	1.1	2	3	2	2	1.12
Approximate osmolality[f] (mOsm/kg water) or osmolarity (mOsm/L)	300 mOsm/kg	350 mOsm/kg	310 mOsm/kg	390 mOsm/kg	284 mOsm/L	292 mOsm/L	293 mOsm/L	380 mOsm/kg	340 mOsm/kg	342 mOsm/kg
Approximate mean pH (range)	8 (6–8.9)			6.8 (6–8.9)	8.3 (6–9)		8.4 (6–9)	6–9	6–9	6–9

[a] Only FDA approved for use in pediatric patients.

[b] Only approved for compounding in a 3-in-1 admixture, not for direct patient administration.

[c] Omega-6 (ω-6) fatty acid.

[d] Omega-3 (ω-3) fatty acid.

[e] One kcal/mL is equivalent to 4.184 kJ/mL.

[f] One mOsm/kg is equivalent to mmol/kg, and one mOsm/L is equivalent to mmol/L.

PL, phospholipid; TG, triglyceride.

Table 100–3

Approximate Daily Maintenance Electrolyte Requirements for Adults[1,12]

Electrolyte	Approximate Daily Maintenance Requirements[a]	Electrolyte Salts Used in PN	Maximum Suggested Concentration in PN
Sodium	1–2 mEq/kg (mmol/kg)	Chloride, acetate, phosphate	154 mEq/L (mmol/L, equivalent to normal saline)
Potassium	1–2 mEq/kg (mmol/kg)	Chloride, acetate, phosphate	120 mEq/L (mmol/L) (central PN)
Phosphorus	20–40 mmol (~10–15 mmol per 1000 kcal [2.4–3.6 mmol per 1000 kJ])	Sodium phosphate, potassium phosphate	See text section on calcium–phosphate solubility Maximum calcium + magnesium = 20 mEq/L in 3-in-1 admixture
Calcium	10–15 mEq (5–7.5 mmol)	Gluconate	
Magnesium	8–20 mEq (4–10 mmol)	Sulfate	20 mEq/L (10 mmol/L)[b]
Chloride	[c]	Sodium, potassium	Linked to limitations of sodium and potassium. Usual ratio of chloride to acetate ~ 1:1 to 1.5:1
Acetate	[c]	Sodium, potassium	
Conversions	1 mmol potassium phosphate = 1.47 mEq potassium 1 mmol sodium phosphate = 1.33 mEq sodium 1 gram of calcium gluconate = 4.65 mEq (2.32 mmol) calcium 1 g of magnesium sulfate = 8.1 mEq (4 mmol) magnesium		

[a] Electrolyte requirements are adjusted based on serum electrolyte concentrations and vary depending on kidney function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, and medication therapy that affect electrolyte losses or retention.

[b] For 3-in-1 formulations only.

[c] As needed to maintain acid–base balance; linked to amounts of sodium and potassium provided (as chloride and acetate salts).

▶ *Fluid*

KEY CONCEPT Parenteral nutrition should not be used to treat acute fluid abnormalities. PN should be adjusted to provide maintenance fluid requirements and to minimize worsening of underlying fluid disturbances, considering other fluids the patient is receiving. Daily maintenance fluid requirements for adults can be estimated with the following equation:

$$\text{Total daily maintenance fluid requirements} \\ = 1500\ \text{mL} + (20\ \text{mL/kg} \times [\text{Wt (kg)} - 20])^{*}$$

For patients with significant fluid deficits, it is safer and more cost effective to correct fluid abnormalities using standard IV fluids. Minimizing PN fluid volume may be indicated in patients with fluid overload, patients with oliguric or anuric acute kidney injury, or those with congestive heart failure or symptomatic pleural effusion. It is reasonable to provide total daily fluid requirements (maintenance requirements and replacement for GI or other abnormal losses) in the PN admixture in patients who require long-term PN if stability and compatibility limits are maintained with dilution of the PN admixture.

Micronutrients

KEY CONCEPT Electrolytes, vitamins, and trace elements are essential for numerous biochemical and metabolic functions and should be added to PN daily unless otherwise not indicated.

▶ *Electrolytes*

KEY CONCEPT Electrolytes are essential for many metabolic and homeostatic functions, including enzymatic and biochemical reactions, maintenance of cell membrane structure and function, neurotransmission, hormone function, muscle contraction, cardiovascular function, bone composition, and fluid homeostasis. The causes of electrolyte abnormalities in patients receiving PN may be multifactorial, including altered absorption and distribution; excessive or inadequate intake; altered hormonal, neurologic, and homeostatic mechanisms; altered excretion and losses via the GI tract (eg, gastric, diarrhea, ostomy, enterocutaneous fistula) and kidneys; changes in fluid status and fluid shifts; and medication therapies. PN should not be used to treat acute electrolyte abnormalities but should be adjusted to meet maintenance requirements and to minimize worsening of underlying electrolyte disturbances.

Electrolytes that are included routinely in PN admixtures include sodium, potassium, phosphorus (as phosphate), calcium, magnesium, chloride, and acetate. Always assess the patient's kidney function when determining electrolyte doses in PN admixtures. Typical daily electrolyte maintenance requirements for adults with normal kidney function are listed in Table 100–3.[1,14] For additional details regarding management of fluid, electrolyte, and acid–base disorders refer to Chapters 28 and 29.

Calcium–Phosphate Solubility The FDA published a safety alert in response to two deaths from microvascular pulmonary emboli associated with calcium–phosphate precipitation in PN.[15] Because calcium and phosphate can bind and precipitate in solution, caution must be exercised when mixing these two electrolytes in PN admixtures. Several factors can affect calcium–phosphate solubility, including:

- *pH:* Largely affected by the amino acid brand and concentration, to a lesser extent by the dextrose concentration; the lower the solution pH, the less chance for calcium–phosphate precipitation. Monobasic phosphates predominate at low pH, leaving fewer free dibasic phosphates for precipitation with divalent calcium; monobasic calcium phosphate is more soluble than dibasic calcium phosphate.

---

[*] For patients greater than 60 years old, use 15 mL/kg for every kilogram above 20 kg.

- *Amino acid brand and concentration:* Primary factor that affects pH of the PN admixture. The pH of amino acid stock solutions may vary between commercial products. In general, the higher the final amino acid concentration, the lower the pH of the final admixture. Phosphates can also bind with amino acids, leaving fewer phosphates available to bind with calcium.
- *Calcium salt:* Calcium gluconate is the preferred calcium salt in PN because it has a lower dissociation constant in solution with less free calcium available at a given time to bind phosphate.
- *Time.* The longer calcium and phosphate are in solution, the more calcium and phosphate will dissociate over time and increase the risk for calcium–phosphate precipitation.
- *Temperature:* As temperature increases, more calcium and phosphate dissociate and increase the risk of calcium–phosphate precipitation.
- *Order of mixing:* Calcium and phosphate should not be added simultaneously or consecutively when compounding PN admixtures (eg, add phosphate first, then add other PN components, and then add calcium near the end of compounding). The volume in the PN admixture at the time calcium is added (not necessarily the final volume) must be used to determine the maximum calcium that can be added.

When compounding PN admixtures, use calcium–phosphate solubility curves (based on the specific brand and final concentration of amino acids and dextrose) to determine safe and appropriate calcium and phosphate concentration limits.

Acetate Acetate is converted to bicarbonate at a 1:1 molar ratio. Bicarbonate should *never* be added to or coinfused with PN admixtures. This can lead to the release of carbon dioxide and result in the formation of insoluble calcium or magnesium carbonate salts.

▶ *Vitamins*

Water-soluble and fat-soluble vitamins in the parenteral multivitamin products are essential cofactors for numerous biochemical reactions and metabolic processes. Parenteral multivitamins are added daily to the PN admixture. Water-soluble vitamins, with the exception of vitamin B_{12}, are generally readily excreted and not stored in the body in significant amounts. Deficiencies of water-soluble vitamins can occur rapidly in the absence of adequate vitamin supplementation in PN. Severe refractory lactic acidosis and deaths were reported in patients who received PN without added thiamin. Thiamin is an essential cofactor in carbohydrate metabolism (via the tricarboxylic acid cycle). Deficiency of thiamin pyrophosphate prevents the formation of acetyl-CoA from pyruvate, which is instead converted to lactate via anaerobic metabolism, resulting in lactic acidosis. Parenteral multivitamin products contain 150 mcg of vitamin K in accordance with FDA recommendations. A parenteral adult multivitamin formulation is available without vitamin K, but standard compounding of PN formulations should include a product that contains vitamin K unless otherwise indicated.

▶ *Trace Elements*

Trace elements are essential cofactors for numerous biochemical processes. Trace elements added routinely to PN in the U.S. include zinc, selenium, copper, manganese, and possibly chromium. ASPEN developed recommendations for daily trace element doses for adult patients receiving PN (Table 100–4). Various individual and multi-ingredient parenteral trace element formulations can be added to PN admixtures. Previously, multi-ingredient formulations in the U.S. did not align with recommended daily parenteral trace element doses, specifically containing higher-than-recommended doses of manganese, chromium, and copper.[16] As part of an initiative to evaluate products that have been on the market since prior to current approval requirements, the FDA has been assessing trace element formulations on the market and approving newer formulations. The first new multi-trace element product, aligning with updated ASPEN recommendations, was approved for adult patients and pediatric patients weighing over 10 kg in July 2020.[17] The new patent exclusivity granted to reformulated single- and multi-trace element products has resulted in a significant increase in the cost of trace elements added to PN.

Trace element dosing and supplementation in PN may require individualization based on the patient's underlying diagnoses, clinical condition, organ function, and unique needs or losses, rather than using a fixed dose multi-trace element product.[18] Some patient populations may require dose reduction of specific trace elements (eg, reduction of manganese and/or chromium doses in long-term PN-dependent patients, reduction of manganese and/or copper doses in patients with cholestasis—serum direct bilirubin concentrations that exceed 2 mg/dL [34.2 µmol/L], etc), and others may require increased/supplemental doses of specific trace elements (eg, increased selenium and/or zinc doses in patients with malabsorption or intestinal losses, especially small bowel losses [high-output enterocutaneous fistulas, short bowel syndrome, diarrhea, etc]). However, it is essential to monitor the patient closely and use patient data to guide therapy decisions (eg, serum trace element levels, signs/symptoms of deficiency or toxicity, clinical and nutritional status) in order to avoid inducing deficiency or toxicity. A complete discussion of all trace element needs and dosing for various patient conditions is beyond the scope of this chapter.

Trace element status should initially be monitored approximately every 3 months in patients at risk for trace element deficiency or accumulation. When stable, serum trace element

Table 100–4

Recommended Daily Parenteral Trace Element Doses for Adults[16,a]

Zinc (Zn)	Selenium (Se)	Copper (Cu)	Manganese (Mn)	Chromium (Cr)
2.5–5 mg	60–100 mcg	0.3–0.5 mg	55 mcg	None or maximum of 1 mcg

[a] Requirements may vary based on patients' kidney function, liver function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, serum levels, and medication therapy. Contamination of some PN ingredients with trace elements (eg, chromium, manganese) can contribute significantly to the total amount the patient receives. Monitor serum trace element levels in patients receiving long-term PN therapy.

From American Society for Parenteral and Enteral Nutrition Board of Directors and the Clinical Guidelines Task Force. Guidelines for the use of parenteral and enteral nutrition in adult and pediatric patients. JPEN J Parenter Enteral Nutr. 2002;26:1SA–138SA.

concentrations can be monitored every 6 to 12 months. These levels should always be interpreted by a knowledgeable nutrition support professional, in context of the clinical stability of the patient (eg, unreliable in context of significant inflammation) and combined with a clinical assessment of signs and symptoms of deficiency or toxicity.

PN Additives

In general, avoid or minimize the use of medication additives in PN admixtures to limit the risk of incompatibilities and improve safety. Some medications are compatible with PN admixtures and appropriate for administration over a prolonged infusion time (eg, 12–24 hours), and it may be reasonable to add these to PN admixtures when indicated.

▶ *Regular Insulin*

Regular insulin may be added to PN admixtures for glycemic control; if that is part of the institution's or individual's practice, it should be done with caution. The dose depends on the patient's clinical condition, severity of hyperglycemia, predisposing factors for hyperglycemia, renal function, and daily insulin requirements. Generally, after the patient is receiving his or her goal dextrose dose in PN and is clinically stable, about 50% to 70% of the total insulin units administered over the previous 24 hours as sliding scale or continuous infusion can be added to the next PN admixture. In patients with type 2 diabetes, typical IV insulin doses in the PN admixture to maintain euglycemia range from 0.05 to 0.2 unit of insulin per gram of dextrose. Use caution when insulin is added to PN to avoid hypoglycemia, especially when reversible causes of hyperglycemia have resolved (eg, stress, acute pancreatitis, corticosteroid therapy) or more than one form of insulin therapy is used concurrently. Adding insulin to PN does not provide the flexibility of frequent titration (vs a continuous IV infusion). Only regular insulin should be added to PN; other forms of insulin should not be added to PN admixtures because they are not a true solution (eg, NPH insulin), and/or their pharmacokinetics/duration of action may not be appropriate for infusion over a prolonged time.

▶ *Histamine-2 Receptor Antagonists*

Intravenous histamine-2 receptor antagonists (eg, famotidine) at typical therapeutic doses are compatible with PN admixtures and can be added when indicated.

▶ *Parenteral Iron*

Chronic PN-dependent patients are at risk for iron deficiency due to underlying clinical conditions and the lack of regular iron supplementation in PN. Although iron dextran may be compatible with lipid-free PN admixtures, iron is not compatible with ILE at therapeutic doses and is not commonly added to PN admixtures due to the incompatibility and the potential for infusion-related reaction. Other parenteral iron formulations (eg, iron sucrose, ferric gluconate) should *not* be added to PN admixtures due to incompatibility or a lack of compatibility data.

▶ *Other Additives*

Other nonnutrient additives should only be included in PN admixtures if there are data supporting physicochemical compatibility and stability and if there are clinical data demonstrating the efficacy and safety of use when administered in the manner of PN administration (ie, continuous infusion over ~12–24 hours).[12]

NUTRITION ASSESSMENT AND NUTRIENT REQUIREMENTS

A nutrition assessment is used to determine a patient's nutritional status, identify patients with malnutrition, identify risk factors for nutrition-related problems, identify or rule out specific nutrient deficiencies, and determine nutrient requirements.[1] A complete description of nutrition assessment is beyond the scope of this chapter, and a nutrition assessment should be completed by a healthcare professional with appropriate training and expertise (eg, dietitian, nutrition-certified pharmacist or nurse, physician). Briefly, key components of a nutrition assessment include[1,19]:

- Patient history.
- Anthropometric measurements including height, weight, ideal body weight (IBW), body mass index (BMI = weight [kg]/height [m^2]), and recent weight changes (intentional or unintentional) (refer to Chapter 102 for additional information).
- Physical examination of the musculoskeletal system (eg, biceps, triceps, quadriceps, temporalis, deltoid, and interosseous muscles) for loss of muscle mass or decreased grip strength, and examination of the skin and mucous membranes for abnormalities (eg, dry or flaky skin, bruising, edema, ascites, poorly healing wounds) and loss of subcutaneous fat.
- Changes in eating habits, GI function, and associated GI symptoms.
- Presence and severity of underlying and concurrent disease(s).
- Serum visceral protein concentrations (eg, albumin, prealbumin). Hypoalbuminemia at baseline or before hospitalization may indicate malnutrition, and severe hypoalbuminemia may be associated with poor outcomes. Serum albumin (half-life ~ 20 days) and prealbumin (half-life ~ 2 days) are negative acute-phase proteins and therefore are neither sensitive nor specific indicators of nutritional status and protein stores in patients under metabolic stress or with evidence of inflammatory response. Measuring C-reactive protein (CRP), white blood cell count, and blood glucose levels may help assess inflammatory response. Synthesis and distribution of albumin and prealbumin may be altered, and serum concentrations are affected by nonnutritional factors, including hydration status, kidney function, and liver function.
- Biochemical evidence of vitamins, trace elements, and iron studies if clinical suspicion and minimal to no inflammation.
- Functional assessment including handgrip strength.

Table 100–5 outlines the two most commonly used sets of criteria for diagnosing malnutrition. Each set of criteria also contains objective parameters to describe severity of malnutrition as either moderate or severe.[19,20]

After performing a nutrition assessment, estimate the patient's daily energy and protein requirements (Table 100–6).[1,2,21,22] Indirect calorimetry involves measuring the volumes of oxygen consumption (VO_2) and carbon dioxide production (VCO_2) to determine the resting metabolic rate (RMR) or resting energy expenditure (REE) and respiratory quotient ($RQ = VCO_2/VO_2$). The REE or RMR is the amount of calories required during 24 hours by the body in a nonactive state and is approximately 10% higher than the basal energy expenditure (BEE, metabolic

Table 100–5

Criteria for Diagnosis of Malnutrition[19,20]

	ASPEN/AND[a] Criteria	GLIM[b] Criteria
Diagnostic Criteria	Requires 2 or more of: • Insufficient energy intake • Weight loss • Loss of muscle mass • Loss of subcutaneous fat • Localized or generalized fluid accumulation that may sometimes mask weight loss • Diminished functional status as measured by hand-grip strength	Requires 1 from each category: Phenotypic • Nonvolitional weight loss • Low body mass index • Reduced muscle mass Etiologic • Reduced food intake or assimilation • Disease burden/inflammatory condition
Diagnosis Categorization	Based on presence and severity of inflammation: • No inflammation: Starvation-related malnutrition (pure chronic starvation, anorexia nervosa) • Mild-to-moderate inflammation: Chronic disease-related malnutrition (organ failure, pancreatic cancer, rheumatoid arthritis, sarcopenic obesity) • Marked inflammatory response: Acute disease or injury-related malnutrition (major infection, burns, trauma, closed head injury)	According to underlying etiology Malnutrition related to: • Chronic disease with inflammation • Chronic disease with minimal or no perceived inflammation • Acute disease or injury with severe inflammation • Starvation including hunger/ food shortage associated with socioeconomic or environmental factors

Table 100–6

Estimating Daily Nutritional Requirements in Adults[1,2,19,21,22]

Determining Energy Expenditure:	
Penn State equations (for critically ill, mechanically ventilated, nonobese adult patients)	$\text{RMR} = (0.85 \times \text{BEE}^a) + (33 \times V_E) + (175 \times T_{max}) - 6433$ $\text{RMR} = (0.96 \times \text{BMR}^b) + (31 \times V_E) + (167 \times T_{max}) - 6212$
Mifflin-St. Jeor equations (for nonobese and obese, non-critically ill adult patients)	Men: $\text{BMR} = (10 \times \text{Wt}) + (6.25 \times \text{Ht}) - (5 \times \text{Age}) + 5$ Women: $\text{BMR} = (10 \times \text{Wt}) + (6.25 \times \text{Ht}) - (5 \times \text{Age}) - 161$
Harris-Benedict equations (historical, not currently recommended for use in acute setting)	Men: $\text{BEE} = 66.42 + (13.75 \times \text{Wt}) + (5 \times \text{Ht}) - (6.78 \times \text{Age})$ Women: $\text{BEE} = 655.1 + (9.65 \times \text{Wt}) + (1.85 \times \text{Ht}) - (4.68 \times \text{Age})$ Energy expenditure then multiplied by a stress factor. To estimate the TEE: Bed rest ≈ 1.2 × BEE Ambulatory ≈ 1.3 × BEE Anabolic ≈ 1.5 × BEE Energy requirements should also be increased ~12% with each degree of fever above 37°C (98.6°F).
Energy expenditure per body weight (ie, kcal/kg)[c]	Range of ~20–30 kcal/kg/day, possibly up to 35 kcal/kg/day Maintenance ~20–25 kcal/kg/day Repletion, postoperative wound healing, critical illness, sepsis, severe trauma, severe burns ~25–30 kcal/kg/day, possibly up to 35 kcal/kg/day

Determining Amino Acid Requirements

Patient Clinical Condition	Daily Amino Acid Requirements[d] (g/kg)
Maintenance or nonstressed	0.8–1
Repletion	1.3–2
Trauma, burns, sepsis, critical illness, wound healing	1.5–2
Hepatic failure with encephalopathy	0.8–1
Acute kidney injury, predialysis	0.8–1
Acute kidney injury receiving IHD	1.2–1.5
Chronic kidney disease receiving CAPD	1.2–1.5
Acute kidney disease receiving CRRT	1.5–2.5

BEE, basal energy expenditure; BMR, basal metabolic rate; CAPD, continuous ambulatory peritoneal dialysis; CRRT, continuous renal replacement therapy; Ht, height (cm); IHD, intermittent hemodialysis; RMR, resting metabolic rate; TEE, total energy expenditure; T_{max}, maximum body temperature in degrees Celsius; V_E, minute ventilation in liters per minute; Wt, weight (kg).

[a] BEE calculated using the Harris-Benedict equation.

[b] BMR calculated using Mifflin-St. Jeor equation.

[c] One kcal/kg is equivalent to 4.184 kJ/kg.

[d] Amino acid requirements are based on actual body weight for normal body sized or malnourished adult patients and on ideal body weight (IBW) for obese patients.

activity required to have variable energy expenditure (EE), and indirect calorimetry is a valuable tool in assessing EE in these patients. Indirect calorimetry requires specific equipment and trained personnel and therefore is not feasible in all settings.

More than 200 equations and derivations have been developed to predict EE for adults, although none of the equations have been demonstrated to be completely accurate, and accuracy varies based on the patient population. The Penn State, Mifflin-St. Jeor, and Harris-Benedict equations are some of the most widely used, and they take into account several variables including a patient's sex, weight, height, age, and mechanical ventilation data to determine the REE (see Table 100–6). A "stress" or "injury" factor is sometimes applied to estimate the daily total EE (TEE), although there is debate about the appropriateness and validity of this approach. Alternatively, EE can be estimated based on body weight. However, dry weight or hospital admission weight should be used, and this estimation may not be appropriate in obese or elderly patients. There is debate over the best method to estimate energy requirements for obese patients. Indirect calorimetry is the preferred method but may not always be available. Several equations have been developed to estimate EE in obese patients. Although there is no consensus on the weight used to estimate EE in obese patients, it is reasonable to use an adjusted body weight (AdjBW) in obese patients to avoid overfeeding. AdjBW can be calculated with 25% to 50% of the difference between the actual weight and IBW added to the IBW. Using a 25% difference in calculating the AdjBW further avoids overfeeding when estimating energy requirements:

$$\text{AdjBW} = \text{IBW} + (0.25 \times [\text{Actual weight} - \text{IBW}])$$

Hypocaloric feeding is another approach for nutrient dosing in obese critically ill patients (discussed below).

Amino acid requirements are based on the patient's nutritional status, clinical condition(s), kidney function, and liver function. Amino acids are needed in adequate amounts to facilitate anabolism, restore lean body mass, and promote wound healing while avoiding adverse effects from excessive amino acid loading (eg, azotemia). No evidence-based data are available confirming the optimal body weight (actual, ideal, or adjusted) to use for dosing amino acids in adult patients. It is suggested to dose amino acids based on actual body weight for normal body sized or malnourished adult patients (ie, when actual weight is at or below IBW) and based on IBW or AdjBW for obese patients.

Hypocaloric nutrition support is an approach to dosing nutrition therapy for obese patients (BMI $\geq$ 30 kg/m^2). Hypocaloric feeding involves providing high doses of protein ($\geq$ 2–2.5 g/kg IBW/day) to support anabolism with lower amounts of total calories (~11–14 kcal/kg [~46–59 kJ/kg] actual weight/day or ~22–25 kcal/kg [~92–105 kJ/kg] IBW/day) with primary goals to promote net protein anabolism and avoid hyperglycemia or exacerbation of metabolic stress in critically ill patients.[2,21] Other benefits could include avoiding fat weight gain or promoting fat weight loss. Most data with hypocaloric feeding are in critically ill adult patients, but this approach has been used in other patients. Hypocaloric feeding should not be used in patients with kidney or liver failure. The optimal safe duration of hypocaloric feeding is unknown.

PARENTERAL NUTRITION SAFETY

Serious and sometimes fatal adverse events have occurred with inappropriate use of PN, and PN is classified as a high-risk medication.[23] Shortages of key PN components have also presented challenges to meet nutritional needs of patients requiring PN therapy. The American Society for Parenteral and Enteral Nutrition (ASPEN) has published several key PN safety documents, including PN safety recommendations[23] and revised guidelines that address PN ordering, order review, compounding, labeling, and dispensing.[12] ASPEN also provides guidance for managing shortages of PN components. These are essential resources for the safe and efficacious use of PN therapy, and they represent the standards of practice for PN prescribing, compounding, stability, compatibility, labeling, administration, and quality assurance. There are several key points and recommendations in these documents to improve the safety of the PN use process, including:

- Adopt published guidelines and literature.
- Develop standardized processes for PN prescribing, order verification, compounding, labeling, dispensing, administering, and monitoring.
- Develop PN-specific policies and procedures.
- Develop education and competency assessments at least annually for all healthcare professionals involved in the PN use process.
- Optimize electronic health records (EHR) and clinical decision support for PN orders.
- Build, test, and heed clinical decision support warnings in EHR systems and in automated compounding devices.
- Avoid use of handwritten PN orders and eliminate manual transcription.
- Match templates between ordering/EHR, compounding software/automated compounding devices, and PN labels.
- PN use process and development of policies, procedures, education, and competencies should include healthcare professionals with expertise in nutrition support, preferably from multiple disciplines.

Although application of these guidelines is voluntary, healthcare professionals who are involved in prescribing, compounding, dispensing, administering, and monitoring PN therapy should review and apply them to their practice.

PREPARING THE PN PRESCRIPTION: ADMINISTRATION, COMPOUNDING, AND PHARMACEUTICAL ISSUES

After performing a nutrition assessment and estimating nutritional requirements, determine the optimal route to provide nutrition support therapy (eg, oral, enteral, or parenteral). If PN is indicated, venous access for PN infusion must be obtained. Finally, formulate a PN prescription and administer PN according to safety guidelines.

Route of PN Administration: Peripheral Versus Central Vein Infusion

KEY CONCEPT PN can be administered via a smaller peripheral vein or via a larger central vein (Figure 100–1). Peripheral PN (PPN) is generally reserved for short-term administration (eg, up to 7 days) when central venous access is not available. PN formulations are hyperosmolar, and thrombophlebitis and extravasation are significant complications that can limit tolerance of PPN therapy.[12] Factors that increase the risk of phlebitis include high solution osmolarity, extreme pH, rapid infusion rate, vein properties, catheter properties (eg, diameter, material), and infusion time via the same vein.[23] The osmolarity of PPN admixtures should be limited to $\leq$ 900 mOsm/L (mmol/L) to minimize the risk of phlebitis.[12]

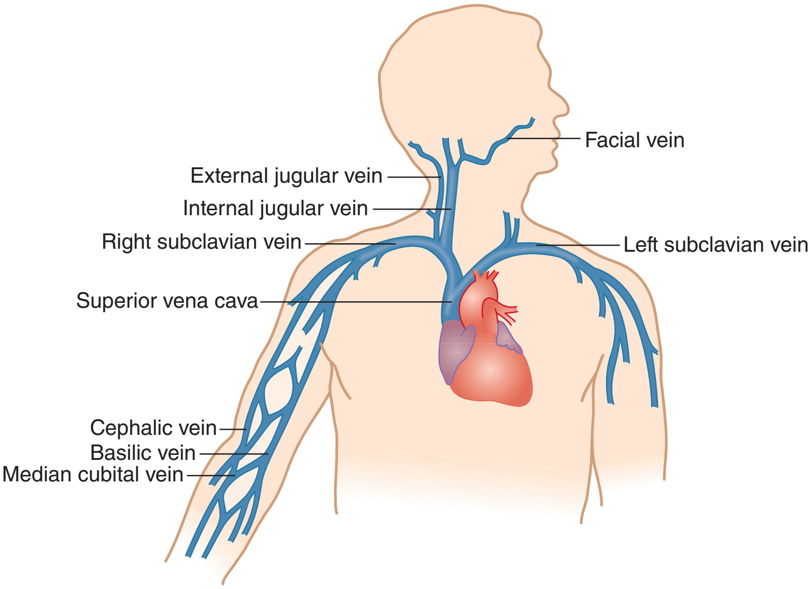

FIGURE 100–1. Selected vascular anatomy. (Reprinted from Neal AM, Drogan K. Parenteral access devices. In: Mueller CM, ed. The ASPEN Adult Nutrition Support Core Curriculum, 3rd ed. Silver Spring, MD: ASPEN; 2017.)

The approximate osmolarity of a PN admixture can be calculated from the osmolarity of the individual components:

- Amino acids ~10 mOsm/g (mmol/g; or 100 mOsm/L% final concentration in PN)
- Dextrose ~5 mOsm/g (mmol/g; or 50 mOsm/L% final concentration in PN)
- Sodium (chloride, acetate, and phosphate) = 2 mOsm/mEq (or 2 mOsm/mmol)
- Potassium (chloride, acetate, and phosphate) = 2 mOsm/mEq (or 2 mOsm/mmol)
- Calcium gluconate = 1.4 mOsm/mEq (2.8 mOsm/mmol)
- Magnesium sulfate = 1 mOsm/mEq (2 mOsm/mmol)

PPN admixtures should be coinfused with ILE when using 2-in-1 PN administration (see "Types of PN Formulations" below) because the iso-osmolarity and near-neutral pH of ILE may decrease the risk of phlebitis (see Table 100–2). Infectious and mechanical complications may be lower with PPN compared with central venous PN administration. Because of the risk of phlebitis, severe soft tissue damage if extravasation occurs, and osmolarity limit, PPN admixtures have low macronutrient concentrations and therefore usually require large fluid volumes to meet a patient's nutritional requirements.[24] These factors limit the utility of PPN therapy, and every effort should be made to obtain central venous access and initiate central PN in patients who have an appropriate indication (see Table 100–1).

Central PN refers to the administration of PN via a large central vein, and the catheter tip must be positioned in the superior vena cava (see Figure 100–1). Central PN allows the infusion of a highly concentrated, hyperosmolar nutrient admixture. The typical osmolarity of a central PN admixture is about 1500 to 2000 mOsm/L (mmol/L). Central veins have much higher blood flow, and the PN admixture is diluted rapidly on infusion, so phlebitis is usually not a concern. Patients who require PN therapy for longer periods of time (> 7 days) should receive central PN. Central PN requires placement of a central venous catheter and an x-ray to confirm placement of the catheter tip. A commonly used central catheter for PN infusion is a peripherally inserted central venous catheter (PICC), which is inserted into a peripheral vein, but the catheter tip is placed in the superior vena cava (Figure 100–2). Patients receiving long-term PN therapy often have a tunneled central venous catheter (Figure 100–3). Central venous catheter placement may be associated with complications, including pneumothorax, arterial injury, air embolus, venous thrombosis, infection, chylothorax, and brachial plexus injury.[1,24]

Types of PN Formulations: 3-in-1 Versus 2-in-1

KEY CONCEPT PN admixtures can be prepared by mixing all components into one container, or ILE may be infused separately

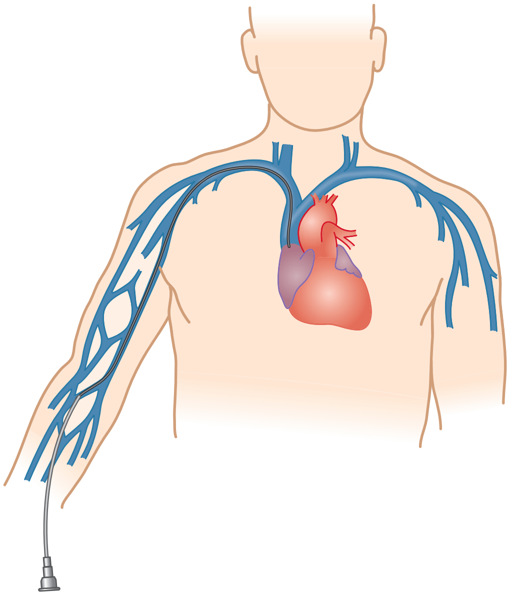

FIGURE 100–2. Peripherally inserted central venous catheter. (Reprinted from Krzywda EA, Andris DA, Edmiston CE, Wallace JR. Parenteral access devices. In: Gottschlich MM, ed. The A.S.P.E.N. Nutrition Support Core Curriculum: A Case-Based Approach—The Adult Patient. Silver Spring, MD: American Society for Parenteral and Enteral Nutrition; 2007:300–322.)

Nutrition Support Core Curriculum: A Case-Based Approach—The Adult Patient. Silver Spring, MD: American Society for Parenteral and Enteral Nutrition; 2007:300–322.)

(via a Y-site infusion or through a separate IV catheter or lumen). When all components are mixed together, it is referred to as a 3-in-1 admixture or TNA. When dextrose, amino acids, and all other PN components are mixed together without ILE (which is infused separately), this is referred to as a 2-in-1 PN admixture. There are various advantages and disadvantages to using either TNA or 2-in-1 PN admixtures (Table 100–7). With a 2-in-1 PN admixture, ILE can be infused separately on a daily or intermittent basis. When ILE is mixed in the PN, the TNA becomes an emulsion with respect to physical and chemical characteristics. The final concentration of ILE in a 3-in-1 admixture should be greater than or equal to 2% (20 g/L) to prevent compromising the stability of the emulsion.[12] Electrolyte, dextrose, and amino acid concentrations may also be more limited in a 3-in-1 admixture.

The FDA has provided recommendations for safe infusion of PN admixtures containing calcium and phosphate:

- A 0.22-μm air-eliminating in-line filter should be used for infusion of non–ILE-containing PN. (A 0.22-μm filter cannot be used on a TNA or ILE infusion line because the average size of ILE particles is approximately 0.3–0.5 μm.)
- A 1.2-μm in-line filter should be used for the infusion of a TNA because it can remove particulates and microparticulates (such as large/unstable fat droplets).[8,23]

Medications should not be admixed or coinfused with PN unless necessary, and it should only be done if reasonable and safe (based on toxicity profile, pharmacokinetic and pharmacodynamic considerations).[23] *Always* consult compatibility data before adding a medication to or coinfusing with a PN admixture. Many IV medications have limited compatibility with 3-in-1 formulations but may be coinfused with a 2-in-1 formulation.[25,26] Some medications can be coinfused at the Y-site; few medications can be mixed directly into the PN admixture or coinfused with ILE; and some cannot be mixed or coinfused with the PN admixture.[25,26]

Standardized, Commercially Available (Premixed or Multichamber) PN Formulations

Standardized, commercially available PN formulations, also called premixed PN formulations or multichamber PN bags (MCBs), are products available from a manufacturer that require fewer compounding steps before administration.[27] These products are available for adult patients in the United States in a two-chamber bag containing amino acids and dextrose with or without electrolytes, or in a three-chamber bag containing amino acids, dextrose, ILE, and electrolytes. However, these products are not “ready to

Table 100–7

Potential Advantages and Disadvantages of Using 3-in-1 (TNA) or 2-in-1 PN Admixtures

	3-in-1 (TNA)	2-in-1
Advantages	Simplified regimen for patient Increased patient compliance at home Decreased labor (less nursing time) Decreased supply and equipment costs Decreased risk of contamination (less manipulation; all components aseptically compounded) Inhibited bacterial growth vs separate ILE Minimize infusion-related reactions from ILE and possibly improved lipid clearance (if infused over > 12 hours) Decreased vein irritation (with PPN)	Improved stability compared with TNA Increased number of compatible medications Decreased bacterial growth (in dextrose–amino acid component) compared with TNA Easier visual inspection Can use 0.22-μm bacterial retention filter
Disadvantages	Decreased stability compared to 2-in-1 PN Cannot use 0.22-μm bacterial retention filter; must use 1.2-μm filter Increased bacterial growth compared with 2-in-1 PN Visual inspection is difficult Limited compatibility with medications	Increased labor and costs (if ILE infused separately) Increased vein irritation with PPN, especially if not coinfused with ILE

ILE, IV lipid emulsion; PN, parenteral nutrition; PPN, peripheral parenteral nutrition; TNA, total nutrient admixture.

administer" as provided; before safely administering to a patient, several essential steps must be completed[23]:

- Manually add vitamins and trace elements.
- ILE can be added to the two-chamber product if desired to create a TNA (or can be infused separately).
- Activate products (ie, break seals between chambers) correctly and then appropriately agitate/mix.
- Manipulations and/or additions to these products should be performed by trained pharmacy personnel.
- Correctly label the product and assign a proper beyond use date and expiration date.
- All of these steps must be completed based on manufacturer instructions, published compatibility and stability data, proper sterile compounding technique, and USP Chapter 797 requirements.

Potential advantages of MCB products include improvements in safety (decreased compounding errors, reduced risk of microbiologic contamination and infections), improvements in ergonomics (reduced time for preparation and administration), and a cost–benefit with comparable nutrition efficacy.[27] The safety advantages are logically related to fewer manual manipulations of the system, but clinical trial data are lacking. In addition, some data suggest an increase in bloodstream infections and hospital costs if additions are made to MCBs under non-aseptic conditions.[27] Cost advantages have been demonstrated in some trials, with others finding no difference or increased costs.[27] Limitations with the use of these products in the United States include relatively low amino acid concentrations, limited available volumes, limited variability in electrolyte content, and no formulations available for neonates and infants. Manufacturers of these products are planning to address some of these limitations with new formulations, including more concentrated amino acid formulation availability in the United States anticipated in early 2021. These limitations may make standardized commercial PN admixtures less appropriate for some patients (eg, critically ill, obese, those with organ dysfunction or who require fluid restriction). Failure to correctly activate or add ingredients to these products will introduce significant safety risks and can lead to patient harm. Finally, conclusions about MCB products should be interpreted with caution because much of the available data are from retrospective studies.

Patient Encounter, Part 2

It is now hospital day #3. Given that DB has malnutrition, an enterocutaneous fistula originating from the jejunum with high output (> 500 mL/day, increased when the patient drank water) and had recent abdominal surgery; the surgery team decided to manage DB conservatively: control fistula drainage, NPO status, and begin parenteral nutrition (PN) support today. A peripherally inserted central catheter (PICC) was placed for PN therapy.

Laboratory Data

Na = 134 mEq/L (mmol/L), K = 3.2 mEq/L (mmol/L), Cl = 91 mEq/L (mmol/L), HCO_3 = 24 mEq/L (mmol/L), BUN = 6 mg/dL (2.1 mmol/L), serum creatinine = 0.4 mg/dL (35 μmol/L), blood glucose = 91 mg/dL (5.1 mmol/L), total Ca = 8.4 mg/dL (2.10 mmol/L)], ionized Ca = 2.38 mEq/L (1.19 mmol/L), Mg = 1.5 mg/dL (0.62 mmol/L), phosphorus = 2.5 mg/dL (0.81 mmol/L), TG = 129 mg/dL (1.46 mmol/L), albumin = 2.9 g/dL (29 g/L), WBC count = 8300/mm^3 (8.3 × 10^9/L), hemoglobin = 11.4 mg/dL (114 g/L; 7.08 mmol/L), hematocrit = 35.1% (0.35), and platelets = 204,000/mm^3 (204 × 10^9/L)

Determine appropriate nutritional goals for DB (calorie and protein requirements).

What other patient data should be collected to help formulate a PN prescription?

Formulating a PN Admixture and Regimen

After completing a full nutrition assessment; estimating the patient's daily fluid, energy, and protein requirements (see Table 100–6); and determining if PN is indicated (see Table 100–1), develop an appropriate PN prescription.

Initiating PN

Exercise caution when initiating PN to avoid hyperglycemia and fluid and electrolyte abnormalities. After determining the goal daily PN volume, initiate PN at a lower infusion rate (eg, ~50% of goal for anywhere from ~6 to 24 hours) on day 1 with no more than 150 to 200 g of dextrose per day (or a maximum initial dextrose infusion rate of ~2 mg/kg/min). Increase PN to goal over the following ~24 hours, provided that glycemic control is maintained and the patient does not experience significant fluid or electrolyte abnormalities. Monitor electrolytes daily and correct as needed. Advance PN more slowly and cautiously in patients with severe malnutrition and monitor for refeeding syndrome (see Complications of PN).

Cycling PN

PN should be administered over 24 hours in most hospitalized patients to minimize glucose, fluid, and electrolyte abnormalities. However, administering PN via an infusion over less than 24 hours, or *cycling PN*, may be advantageous in certain patients and situations. Cycling PN involves administering the same PN formulation over a goal infusion time, usually over 12 to 18 hours, rather than over 24 hours. Begin with the PN infusion over 24 hours, then adjust the PN infusion to the goal cycle over 2 to 4 days (eg, 24 hours, then 18–20 hours the next day, then 14–16 hours the next day, and then 12 hours the next day). Titrate the PN infusion rate up over 1 to 2 hours to peak rate to avoid hyperglycemia and taper down over 1 to 2 hours at the end of the

Patient Encounter, Part 3

The surgical team asks for your recommendations for PN therapy for DB.

Develop a plan for a complete and balanced PN prescription for amino acids (including fluid, total calories, dextrose, amino acids, ILE, electrolytes, vitamins, trace elements, and any additives) and explain the rationale supporting your PN formulation and plan.

How should this PN admixture be initiated and titrated to goal?

Would you recommend any other treatments before initiating PN? (Hint: Is this patient at risk for refeeding syndrome?)

cycle to avoid reactive hypoglycemia. Most home infusion pumps can be programmed to cycle a given PN volume automatically over a given time; however, the clinician may have to develop an appropriate PN cycle if this functionality is not available.

Cyclic PN has the following potential advantages:

- It may improve the quality of life of patients receiving home PN by allowing the patient time off PN to engage in normal activities of daily living.
- While data are limited, it may help prevent and alleviate PN-associated liver disease by avoiding continuous compulsive nutrient overload on the liver.[28]

Concerns with cycling PN include hyperglycemia with high infusion rates, reactive hypoglycemia when PN infusion is stopped, and fluid and electrolyte abnormalities. Longer cycle times may limit these adverse effects. Random capillary blood glucose concentrations should be checked ~1 to 2 hours after reaching goal rate, 15 to 60 minutes after PN stops, and intermittently during the PN cycle as needed for glycemic control. Consider checking blood glucose after the PN cycle has ended only if the patient has signs/symptoms of hypoglycemia. This approach may prevent inadvertent treatment of borderline elevated glucose concentrations once PN has stopped and subsequently inducing hypoglycemia. During cyclic PN infusion, the potassium infusion rate should not exceed 10 mEq/hour (mmol/hour) if the patient is not on a cardiac monitor. If nocturnal cyclic PN infusion interferes with patient's sleep pattern by causing overdiuresis, the PN cycle can be extended over a longer infusion time, or PN can be infused during other times of the day that are most convenient to the patient.

Transition to Oral or Enteral Nutrition

The goal is to transition the patient to enteral or oral nutrition and taper off PN as soon as indicated. After initiation of enteral or oral nutrition, monitor the patient for glucose, fluid, and electrolyte abnormalities. When oral nutrition intake is inconsistent, perform calorie counts to determine the adequacy of nutrition via the oral route. When the patient is tolerating more than 50% of total estimated daily calorie and protein requirements via the oral or enteral route, decrease PN by about 50%. PN can be stopped when the patient is tolerating at least 75% of total daily calorie and protein requirements via the oral or enteral route, assuming that intestinal absorption is maintained.

COMPLICATIONS OF PN

KEY CONCEPT PN therapy is associated with significant complications, both with short- and long-term therapy (Table 100–8). Many complications are related to overfeeding (Table 100–9).

Table 100–8

Complications Associated With Parenteral Nutrition

Short Term	Long Term
Hyperglycemia	Infectious complications
Hypoglycemia	Liver toxicity
Electrolyte abnormalities	Vitamin abnormalities
Refeeding syndrome	Trace element abnormalities
Acid–base disturbances	Metabolic bone disease
Hyperlipidemia	Catheter/mechanical complications
Hypercapnia	
Infectious complications	
Catheter/mechanical complications	

Hyperglycemia

Hyperglycemia is one of the most common complications associated with PN therapy in adult patients.[24] Patients with stress and hypermetabolism (eg, trauma, burns, sepsis, severe acute pancreatitis) often have hyperglycemia due to increased endogenous glucose synthesis, decreased cellular glucose uptake, and increased insulin resistance.[29,30] Patients with diabetes and patients receiving certain medications (eg, corticosteroids, vasopressors, octreotide, tacrolimus) can also experience hyperglycemia. Uncontrolled hyperglycemia can lead to fluid and electrolyte disturbances, hyperglycemic hyperosmolar nonketotic syndrome, hypertriglyceridemia, organ dysfunction, increased infections, and increased mortality.[24,29,31] Critical illness is associated with increased endogenous glucose production (caused by increased glycogenolysis and gluconeogenesis) and insulin resistance.[29-31] Therefore, critically ill patients have lower tolerance for dextrose infusion compared with nonstressed patients. A portion of daily calories (~20%–30%) can be administered via ILE to help decrease hyperglycemia, provided that the patient does not have hypertriglyceridemia. Always avoid overfeeding (with dextrose and with total calories). Most recent data suggest that moderate glucose control is indicated in adult hospitalized patients receiving nutrition support (eg, capillary glucose concentrations between ~140 and 180 mg/dL [7.8 and 10.0 mmol/L]).[32] Refer to "PN Additives: Regular Insulin" regarding management of hyperglycemia with insulin in PN.

Hypoglycemia

Hypoglycemia can occur in patients when PN is interrupted suddenly (reactive hypoglycemia), especially when patients are treated with insulin or as a result of insulin overdosing.[1] It is essential to prevent hypoglycemia and, if it occurs, identify and treat it promptly. Reactive hypoglycemia typically is rare and usually can be avoided by tapering PN over 1 to 2 hours before discontinuation rather than abruptly stopping the infusion (especially if the patient is receiving insulin or if the patient is not receiving oral or enteral nutrition). Reactive hypoglycemia generally occurs within 15 to 60 minutes after stopping PN, although it can occur later than this after discontinuing PN.[1] Capillary blood glucose concentrations should be monitored about 15 to 60 minutes after stopping PN infusion to detect any potential hypoglycemia. If PN is interrupted abruptly (eg, because of lost IV access), infusing an

Table 100–9

Consequences of Overfeeding

Source of Overfeeding	Consequences
Dextrose	Hyperglycemia, hypertriglyceridemia, hepatic steatosis, hypercapnia; hyperglycemia may cause fluid and electrolyte disturbances and increased infection risk
IV lipid emulsions	Hypertriglyceridemia, hyperlipidemia, hepatic steatosis
Amino acids	Azotemia
Total calories	Hepatic steatosis, cholestasis, hypercapnia

IV solution containing dextrose 10% in water at the same rate as PN should prevent hypoglycemia. In patients with poor venous access, reduce the PN infusion rate by 50% for 1 hour before discontinuing. Another alternative to prevent reactive hypoglycemia is to provide a glucose source via the oral or sublingual route when feasible.

Hyperlipidemia/Hypertriglyceridemia

Patients receiving ILE may be at risk for hyperlipidemia and hypertriglyceridemia. Hyperlipidemia in patients receiving PN may lead to a reduction in pulmonary gas diffusion and pulmonary vascular resistance.[24,31] Severe hypertriglyceridemia (especially serum triglyceride concentrations exceeding 1000 mg/dL or 11.30 mmol/L) can precipitate acute pancreatitis.[7,31] Hypertriglyceridemia may develop as a result of increased fatty acid synthesis caused by hyperglycemia, impaired ILE clearance, in patients with history of hyperlipidemia, obesity, diabetes, alcoholism, kidney failure, liver failure, multiorgan failure, sepsis, or pancreatitis, or as a result of medications (eg, propofol, corticosteroids, cyclosporine, sirolimus).[31] Hyperglycemia is probably one of the most common causes of hypertriglyceridemia in patients receiving PN.[31]

Monitor serum triglyceride concentrations regularly during PN therapy (see Table 100–9). If a patient develops hypertriglyceridemia, identify and correct the underlying cause(s) if possible. Prolonging the infusion of ILE may improve lipid clearance. If a patient is receiving propofol, ILE should be withheld and the triglyceride load and calories from the 10% ILE in propofol should be considered (see Table 100–2). ILE should be held when the serum is lipemic or when serum triglyceride concentrations are greater than 400 mg/dL (4.52 mmol/L). When this occurs, restart ILE when the serum triglyceride concentration is approximately 200 to 400 mg/dL (2.26–4.52 mmol/L) (or less) and administer only the equivalent of 100 g soybean oil ILE per week, either as divided doses of soybean oil ILE or as one of the alternative ILE products, to prevent EFAD. Avoid completely holding ILE for more than 3 to 4 weeks due to risk of EFAD.

Hypercapnia

Hypercapnia can develop because of overfeeding with dextrose and/or total calories.[1,31,33] Excess carbon dioxide production and retention can lead to acute respiratory acidosis. Excess carbon dioxide will also stimulate an increase in respiratory rate, and this increase in respiratory workload could cause respiratory insufficiency that may require mechanical ventilation. Reducing total calorie and dextrose intake would result in resolution of hypercapnia if due to overfeeding.

Liver Complications

The incidence of liver complications associated with PN ranges from approximately 7% to 84%, and end-stage liver disease historically developed in as many as 15% to 40% of adult patients on long-term PN (likely lower in current practice with avoidance of overfeeding).[31] Patients may develop a mild increase in liver transaminases within 1 to 2 weeks of initiating PN, but this generally resolves as PN continues, provided overfeeding is avoided. Severe liver complications include hepatic steatosis, steatohepatitis, cholestasis, PNALD, and cholelithiasis.[24,31,34]

Hepatic steatosis is usually a result of excessive administration of carbohydrates or fats, but deficiencies of carnitine, choline, and essential fatty acids also may contribute. Hepatic steatosis can be minimized or reversed by avoiding overfeeding, especially from dextrose and ILE.[31]

PNALD is described as decreased bile flow not caused by mechanical obstruction or other causes of liver disease in patients receiving long-term PN therapy.[34] Factors that predispose PN patients to cholestasis and PNALD include lack of enteral nutrition, use of soybean oil–based ILE (which contains high amounts of omega-6 fatty acids and potentially toxic phytosterols), exposure to aluminum, overfeeding, bowel rest, long duration of PN, short bowel syndrome, bacterial overgrowth and translocation, and sepsis.[24,31,34] Patients may exhibit increased serum liver transaminase (aspartate aminotransferase [AST], alanine aminotransferase [ALT]), alkaline phosphatase and γ-glutamyl transferase (GGT) concentrations, and mainly increased bilirubin concentrations with jaundice. The most sensitive marker of cholestasis is increased serum conjugated (direct) bilirubin concentration of greater than 2 mg/dL (34.2 μmol/L).[31] Cholestasis generally is reversible if PN is discontinued before permanent liver damage occurs. Serum liver function tests may take up to 3 months to return to normal after discontinuing PN. Steps to prevent cholestasis associated with PN include early enteral or oral feedings, using a balanced PN formulation, avoiding overfeeding, using cyclic PN infusion, and treating and avoiding sepsis.[31] Reducing the dose of soybean oil–based ILE (ie, "lipid restriction") or using one of the alternative ILE products (lower in omega-6 fatty acids, lower in potentially toxic phytosterols) may be effective in the treatment of cholestasis and PNALD.[8,34] Monitor for EFAD in patients receiving reduced doses of ILE or alternative ILE products. Pharmacologic treatments include ursodeoxycholic acid (ursodiol), which may improve bile flow and reduce the signs and symptoms of cholestasis. Ursodiol is only available in an oral dosage form, and absorption may be limited in patients with extensive intestinal resections.

Cholelithiasis can develop because of decreased gallbladder contractility, especially in the absence of enteral or oral intake. Lack of intestinal stimulation reduces secretion of cholecystokinin, a peptide hormone secreted in the duodenum that induces gallbladder contractility and emptying. The best prevention of cholelithiasis is early initiation of enteral or oral feeding.

Monitor liver function tests, including serum AST, ALT, alkaline phosphatase, total bilirubin, conjugated bilirubin, unconjugated bilirubin, and GGT at the initiation of PN therapy and regularly thereafter during PN therapy. The frequency of monitoring liver function tests depends on the presence or absence of liver disease, ranging from once weekly in the acute setting to monthly or less frequently in stable home PN patients.

Manganese Toxicity

Manganese accumulation can occur in patients with cholestasis or in patients receiving long-term PN therapy. Neurotoxicity is the most common manifestation (headache, somnolence, weakness, confusion, tremor, muscle rigidity, altered gait, and mask-like face [a Parkinson-like syndrome]), but liver toxicity may also occur.[31] Periodically monitor blood manganese concentrations in patients on long-term PN. Patients with cholestasis receiving PN may require restriction of manganese in PN to prevent accumulation and possible toxicity.

Metabolic Bone Disease

Metabolic bone disease (MBD) is a condition of bone demineralization leading to osteomalacia, osteopenia, or osteoporosis in patients receiving long-term PN. MBD may occur in as many as 40% to 100% of patients receiving long-term PN.[31] Often patients are asymptomatic, although symptoms can include bone pain, back pain, and fractures. Patients often have increased serum alkaline phosphatase concentrations, low to normal parathyroid hormone (PTH) concentrations, normal 25-hydroxyvitamin D and low 1,25-dihydroxyvitamin D concentrations, hypercalcemia or hypocalcemia, and hypercalciuria.[35] Because patients may be asymptomatic, diagnosis can be incidental. Radiographic techniques commonly used in diagnosing bone disease include quantitative computed tomography (CT) and bone mineral density.[35]

Factors that can predispose patients to developing MBD include deficiencies of phosphorus, calcium, and vitamin D; aluminum toxicity; amino acids and hyperosmolar dextrose infusions; chronic metabolic acidosis; corticosteroid therapy; and lack of mobility.[31,35] Calcium deficiency (caused by decreased intake or increased urinary excretion) is one of the major causes of MBD in patients receiving PN. Provide adequate amount and balance of calcium and phosphate with PN to improve bone mineralization and help to prevent MBD.

Aluminum toxicity appears to play a role in the development of MBD in patients on long-term PN, possibly by impairing calcium bone fixation, inhibiting the conversion of 25-hydroxyvitamin D to the active 1,25-dihydroxyvitamin D, and/or reducing PTH secretion.[31,35] The FDA issued a rule specifying acceptable aluminum concentrations in parenteral products used in compounding PN admixtures,[36] indicating that products contain no more than 25 mcg/L (0.93 μmol/L) of aluminum and defined a safe upper limit for parenteral aluminum intake at less than 4 to 5 mcg/kg/day. Pharmacies should use products with the lowest labeled aluminum content for the making of PN.

Encourage patients on long-term PN to engage in regular low-intensity exercise. Yearly bone density measurements also should be performed on patients on long-term PN and when MBD is suspected.

Refeeding Syndrome

Refeeding syndrome describes the metabolic derangements that occur during reintroduction of nutrition in patients who are starved, underweight, or severely malnourished.[37] Hypophosphatemia and hypokalemia (along with associated complications) are the classic signs and symptoms, but refeeding syndrome encompasses a constellation of electrolyte abnormalities and possibly thiamin deficiency affecting neurologic, cardiac, hematologic, neuromuscular, and pulmonary systems. Symptoms can range from mild to severe, and the most severe cases of refeeding syndrome have resulted in cardiac failure, seizures, coma, and death. Most of the literature on refeeding syndrome is based on retrospective observations and case reports, and high-quality clinical data are lacking.[37]

The reintroduction of energy substrates, especially carbohydrates, increases metabolism and utilization of glucose as the predominant fuel source. This increases insulin secretion and demand for phosphorylated intermediates of glycolysis (eg, ATP and 2,3-diphosphoglycerate [2,3-DPG]), inhibits fat metabolism, and causes an intracellular shift of phosphorus, potassium, and magnesium. These changes, potentially in combination with preexisting low total body stores of phosphorus, potassium, and magnesium in starved or malnourished individuals, and enhanced cellular uptake of phosphorus during anabolic refeeding, can result in hypophosphatemia, hypokalemia, and hypomagnesemia. Vitamin deficiencies (eg, thiamin) also may exist or be precipitated during refeeding. High carbohydrate intake increases the demand for thiamin, which can precipitate thiamin deficiency and cause lactic acidosis and neurologic abnormalities,[2] and possibly myocardial dysfunction.[37] Other metabolic alterations that may occur include expansion of the extracellular water compartment and edema, although it is not clear if this is a direct consequence of refeeding syndrome.[37]

Recent consensus recommendations suggest diagnosing refeeding syndrome based on the following occurring within 5 days of reintroducing or substantially increasing energy provision: a decrease in any one or more of serum phosphorus, potassium, and/or magnesium by 10% to 20% (mild), 20% to 30% (moderate), or greater than 30% (severe) and/or organ dysfunction that results from these electrolyte abnormalities and/or due to thiamin deficiency (severe).[37]

The primary goal is preventing refeeding syndrome when initiating PN in patients at risk[37]:

- Lack of adequate nutritional intake for more than 5 to 7 days or intake of less than 50% to 75% of estimated needs for more than 1 month or more than 5 to 7 days if acutely ill
- Approximately 5% to 10% weight loss
- Moderate-to-severe malnutrition
- Presence of electrolyte abnormalities prior to initiating feeding
- Loss of muscle and/or subcutaneous fat
- Anorexia nervosa
- Mental health disorders
- Alcohol and substance use disorders
- Cancer
- Bariatric surgery
- Extensive intestinal resection
- Malabsorption
- Critical illness

When initiating nutrition support, the rule of thumb to mitigate refeeding syndrome is generally to “start low and go slow.” Although carbohydrates are the primary macronutrient precipitating refeeding syndrome, most guidelines include dosing recommendations based on total calories. Initiate PN cautiously (eg, ~100–150 g of dextrose or ~10–20 kcal/kg (~42–84 kJ/kg) for the first 24 hours and gradually increase by ~33% of goal calories every 1 to 2 days.[37,38] When using standardized, commercially available PN admixtures, consider selecting a formulation with a lower dextrose concentration for the first several days of therapy. Correct electrolyte abnormalities before initiating PN and provide supplemental phosphate, potassium, and magnesium in and/or outside of PN. Doses of IV phosphate up to 0.64 to 1 mmol/kg may be used to treat severe hypophosphatemia (in patients with normal kidney function), and doses can be repeated as needed until serum phosphorus concentration has normalized.[39] Provide supplemental oral or IV thiamin 100 mg/day for 5 to 7 days in patients at high risk for deficiency or with known or suspected deficiency, in addition to the standard multivitamin in PN.[37] Assess patients for fluid balance, signs of edema, fluid overload, and weight gain; it is reasonable to be cautious with fluid and sodium intake during the first few days of PN.[2] Monitor patients closely for signs and symptoms of refeeding syndrome until they are tolerating PN at goal for a few days[37]:

- Vital signs, mental status, and neurologic and neuromuscular function every 4 hours
- Pulse oximetry and any electrocardiographic changes when indicated

Table 100–10

Suggested Frequency of Monitoring Parameters in Hospitalized Patients Receiving PN

Parameters	Initial	Daily (Unstable)	2–3 × Weekly (Stable)	Weekly	As Indicated
BUN, creatinine	X	X	X		
Sodium, potassium, chloride, bicarbonate	X	X	X		
Glucose	X	X	X		
Calcium, phosphorus, magnesium albumin, AST, ALT, LDH, alkaline phosphatase, total bilirubin	X	X	X		
Conjugated bilirubin	X			X	X
Prealbumin[a]	X				X
Triglycerides	X			X	X
RBC count, hemoglobin, hematocrit, WBC count ± differential, platelets, PTT	X				X
PT or INR				X	X
Nitrogen balance					X
Zinc, selenium, chromium, copper, manganese, iron					X
TIBC, ferritin					X
Vitamin concentrations					X
Blood cultures					X
Body weight	X	X	X		

[a] Only recommended/indicated in the absence of inflammatory response.

ALT, alanine aminotransferase; AST, aspartate aminotransferase; BUN, blood urea nitrogen; INR, international normalized ratio; LDH, lactate dehydrogenase; PT, prothrombin time; PTT, partial thromboplastin time; RBC, red blood cell; TIBC, total iron-binding capacity; WBC, white blood cell.

- Serum laboratory values (including phosphorus, potassium, magnesium, and sodium) every 12 hours for the first 3 days, possibly more frequently depending on the patient's clinical status

Consider developing a specific electrolyte replacement protocol or plan for patients with evidence of refeeding syndrome. If a patient develops hypophosphatemia, hypokalemia, and/or hypomagnesemia during initiation of nutritional intake or when increasing nutrition delivery, other signs or symptoms of refeeding syndrome, decreasing dextrose intake by ~50% (or consider decreasing to the amount provided on day 1, or decreasing to ~ 20 kcal/hour [84 kJ/hour]) and gradually increase by ~33% of goal every 1 to 2 days back to goal.[37,38] Given the lack of robust literature and clinical trials on refeeding syndrome, it is important to monitor the patient carefully and adjust PN and other treatments based on clinical judgment and the patient's response and clinical condition.

Infectious Complications

Patients receiving central PN are at increased risk of developing infectious complications caused by bacterial and fungal pathogens.[1,24,40] Earlier studies found that patients without malnutrition who receive early PN (eg, within 48 hours of ICU admission) may have a higher incidence of infectious complications than patients who do not receive PN or receive late PN initiation (eg, > 7 days after ICU admission).[2,3,41] However, more recent studies have not demonstrated this same risk (potentially due to avoiding overfeeding, improvements in catheter care, glycemic control, and other aspects of ICU care).[42,43] Strict aseptic techniques must be used when placing the catheter along with continuous care of the catheter and infusion site. Catheter-related bloodstream infections are a common complication in long-term PN patients, often requiring hospital admission for parenteral antimicrobial therapy and/or removal of the catheter. Contamination of the PN admixture is possible but rare if protocols are followed for aseptic preparation of PN admixtures.

Mechanical Complications

Mechanical complications of PN are related to venous catheter placement and the equipment used to administer PN. A central venous catheter must be placed by a trained professional, and risks associated with placement include pneumothorax, arterial puncture, bleeding, hematoma formation, venous thrombosis, and air embolism.[1,24] Over time, the venous catheter may require replacement. Problems with the equipment include malfunctions of the infusion pump, IV tubing sets, and filters.

MONITORING PN THERAPY

KEY CONCEPT When initiating PN, patients should have important baseline laboratory values checked to assess electrolyte status, organ function, and nutritional status. Thereafter, these and other nutritional parameters should be monitored routinely or as indicated. Random capillary blood glucose concentrations also should be monitored every 6 to 8 hours when initiating PN, and regular insulin should be administered to control blood glucose concentrations as needed (Table 100–10).

Patient Encounter, Part 4

The surgical team plans to initiate PN for DB per your recommendations. Laboratory data were listed previously.

What monitoring parameters related to PN therapy should you follow in DB after initiating PN? List monitoring parameters and frequency.

What potential complications of PN should you monitor for in DB?

What special considerations must be made when developing a plan for nutrition support therapy and a PN formulation for patients with severe malnutrition?

Patient Care Process: Parenteral Nutrition

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings.
- Review diet/nutritional intake history (or perform this history if not available).
- Identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication and food access and other aspects of care.

Assess the Information:

- Determine whether the patient is taking any substance that could adversely affect nutritional status, nutrient intake, or interact with prescribed medications or specialized nutrition support.
- Review relevant laboratory tests pertinent to nutrition status and fluid/electrolyte balance (eg, electrolytes, lipids, liver panel, renal function, A_{1C}, basic metabolic profile, complete blood count).
- Determine whether the patient is at risk of refeeding syndrome or short- or long-term complications of parenteral nutrition.
- Determine or assess appropriateness of the patient's macronutrient goals.
- Assess the efficacy, safety, and patient adherence of current pharmacotherapy and specialized nutrition support.
- Identify any significant adverse drug effects or drug–drug or drug–nutrient interactions.

Develop a Care Plan:

- If patient is at risk for refeeding, develop plan for preventing refeeding while initiating and advancing parenteral nutrition.
- Develop an initial, and subsequently a goal, parenteral nutrition formulation that is appropriate, safe, and pharmaceutically stable/compatible.
- Once stabilized on goal nutrition regimen, determine monitoring plan appropriate for the patient's current clinical status.
- Develop cycle regimen for parenteral nutrition if patient has an indication for cycling PN.
- If patient unable to take oral medications, determine which medications can be given via alternate routes or identify other medication changes needed to address comorbid conditions.

Implement the Care Plan:

- Educate the patient about changes in drug and nutrition therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Review the patient's practices and technique for self-administration of parenteral nutrition (including sterile technique) if patient will self-manage at home.
- Address any patient concerns about parenteral nutrition and its management.
- Determine whether the patient has insurance coverage for home parenteral nutrition if indicated.

Follow-up: Monitor and Evaluate:

- Follow up at regular intervals (frequency as appropriate for clinical status and stability of parenteral nutrition regimen) with laboratory monitoring.
- Review parenteral nutrition adherence, administration technique, any changes in oral or enteral nutrition intake, and gastrointestinal function (indication for parenteral nutrition).
- Review physical examination, laboratory tests, and results of other diagnostic tests to assess for short- and long-term complications of parenteral nutrition.

SUMMARY AND CONCLUSION

PN is an effective and potentially lifesaving therapy for patients who cannot receive adequate oral or enteral nutrition. The PN use process and PN orders are complex, and there are a number of significant safety concerns with PN ordering and order review, compounding, and administration. PN therapy can be associated with significant adverse effects and metabolic, infectious, and mechanical complications. Healthcare professionals must take appropriate steps to optimize the safety of PN therapy and the PN use process to minimize the risk of adverse effects and complications, and patients must be monitored closely while receiving PN to optimize outcomes.

Abbreviations Introduced in This Chapter

AdjBW	Adjusted body weight
ALT	Alanine aminotransferase
ASPEN	American Society for Parenteral and Enteral Nutrition
AST	Aspartate aminotransferase
ATP	Adenosine triphosphate
CT	Computed tomography
2,3-DPG	2,3-Diphosphoglycerate
FDA	Food and Drug Administration
GI	Gastrointestinal
IBW	Ideal body weight
ILE	Lipid injectable emulsion
kcal	Kilocalorie(s)
kJ	Kilojoule(s)
LDH	Lactate dehydrogenase
MBD	Metabolic bone disease
mEq	Milliequivalents
mmol	Millimoles
mOsm	Milliosmoles
PL	Phospholipid(s)
PN	Parenteral nutrition
PPN	Peripheral parenteral nutrition
PTH	Parathyroid hormone
TG	Triglyceride
TNA	Total nutrient admixture
TPN	Total parenteral nutrition

101 Enteral Nutrition

Sarah J. Miller

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Discuss how gut structure and function impact choice of feeding route and outcome of feeding.
2. Estimate kilocalorie and protein requirements of an enteral feeding candidate and design an enteral nutrition (EN) regimen to meet these.
3. Evaluate patient-specific parameters to determine whether EN is appropriate.
4. Compare clinical efficacy, complications, and costs of EN versus parenteral nutrition (PN).
5. Formulate a monitoring plan for an EN patient.
6. Select appropriate medication administration techniques for an EN patient.

INTRODUCTION

Enteral nutrition (EN) is broadly defined as delivery of nutrients via the gastrointestinal (GI) tract. The terms *enteral nutrition* and *tube feedings* are often used synonymously. Formulas for EN usually are delivered in the form of commercially prepared liquid preparations, although some products are produced as powders for reconstitution, and some patients may appropriately receive specific blenderized foods via feeding tubes.[1] Nonvolitional feedings, in patients who cannot meet nutritional requirements by oral intake, include EN and parenteral nutrition (PN), which are collectively known as *specialized nutrition support* (SNS).

Several organizations have issued EN clinical guidelines. These include the American Society for Parenteral and Enteral Nutrition (ASPEN), European Society for Clinical Nutrition and Metabolism (ESPEN), and a Canadian team known as Critical Care Nutrition.[2-4] ASPEN and the Society for Critical Care Medicine (SCCM) have jointly issued guidelines for SNS in critically ill patients and COVID-19 patients.[5,6]

GI TRACT STRUCTURE AND FUNCTION

Anatomy and Absorptive Function

With normal volitional feeding, food is ingested via mouth. There, the process of breaking down complex foodstuffs into simpler forms begins. Solid food is chewed in the mouth, and enzymes begin digestion. Presence of food in specific GI tract regions triggers release for many enzymes and GI hormones. Food is swallowed and passes through the esophagus and the esophageal sphincter to the stomach, where additional digestive enzymes and acids further break it down. The stomach also mixes and grinds.

Food, now in liquid form known as *chyme*, passes through the pyloric sphincter into the duodenum, where stomach acid is neutralized. Food then passes into the jejunum, where most absorption of digested carbohydrate and protein occurs. Most fat absorption occurs within the jejunum and ileum, the final segment of the small bowel. The absorptive units on the intestinal mucosal membrane are infoldings known as *villi*, which are made up of epithelial cells called *enterocytes.* Projections from these enterocytes, called *microvilli*, increase surface area of the small bowel and make up the *brush-border membrane.*

Digestive substances secreted by the pancreas play a role in food breakdown. Large amounts of sodium bicarbonate neutralize stomach acid. Digestive substances flow from the pancreas through the pancreatic duct. The pancreatic duct typically joins the hepatic duct to become the common bile duct that empties through the sphincter of Oddi into the duodenum. Bile salts secreted by the liver help emulsify fat and facilitate fat absorption. Bile flows through bile ducts into the hepatic duct and common bile duct. Bile is stored in the gallbladder until needed to aid fat digestion, at which time it empties through the cystic duct to the common bile duct to the duodenum. Figure 101–1 illustrates digestion and absorption of nutrients.

Remaining undigested food passes from the ileum through the ileocecal valve to the colon. A major role of the colon is fluid absorption. Some water and sodium absorption is facilitated by short-chain fatty acids (SCFAs) formed from digestion of certain dietary fibers by colonic bacterial enzymes.

Gut Immune Function

The gut plays significant immune roles. The distal small bowel and colon host many bacteria and their endotoxins, and it is important that these organisms not gain access to internal body systems. This function is known as the *gut barrier function*.[7] Normal gut flora comprise one component. Normal flora, particularly some anaerobes, help prevent overgrowth of potential pathogens. A second component involves mechanical factors, including a mucus layer that prevents bacterial adherence. Small bowel peristalsis prevents bacterial stasis. Gut-associated lymphoid tissue (GALT), prominent in the small bowel, serves as a local immune system. Secretory immunoglobulin A produced at the mucosal surface in response to food prevents bacteria from invading the surface.

FIGURE 101–1. Schematic of carbohydrate, fat, and protein digestion. (From Kumpf VJ, Mulherin DW. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 11th ed. New York, NY: McGraw-Hill; 2020; Figure 160–1.)

PATIENT SELECTION

In general, KEY CONCEPT EN is the preferred route if the gut can be used safely in patients who cannot meet nutritional requirements by oral intake, rather than PN. The timing of SNS (either EN or PN) is controversial.[3,6] Previously well-nourished patients can better afford not being fed for longer periods than previously poorly nourished patients. Most patients in the intensive care unit (ICU) benefit from early EN started within 24 to 48 hours of ICU admission.[3,6] Methods for assessing nutritional status and designing SNS regimens are covered in Chapter 100. Generally, nonobese hospitalized patients require 20 to 35 total kcal/kg of body weight/day (84–147 kJ/kg body weight/day) and 1.2 to 2 g protein/kg of body weight/day. Obese patients are often fed hypocaloric, high-protein diets; guidelines state to start feedings at 1.2 g protein/kg of actual body weight (or 2–2.5 g/kg of ideal body weight) and less than 14 kcal/kg actual body weight (59 kJ/kg actual body weight).[8]

Indications

Many potential indications for EN exist (Table 101–1). PN was used extensively in the past, but advances in EN technology now allow many patients to receive EN in both institutional and home settings.

Contraindications and Precautions

EN should be avoided or used with caution in certain conditions (Table 101–2). It is possible to use EN in some of these patients depending on severity of illness, location of abnormality, and experience of practitioners delivering care. Feeding in hemodynamic instability is controversial; the 2016 ASPEN/SCCM critical care guidelines recommend withholding feedings in hypotension or when vasopressors are being initiated or escalated.[6,9,10]

Table 101–1

Potential Indications for EN

Neoplastic Disease	**GI Disease**
Chemotherapy	Inflammatory bowel disease
Radiation therapy	Short bowel syndrome
Upper GI tumors	Esophageal motility disorder
Cancer cachexia	Pancreatitis
Organ Dysfunction	Fistulas
Liver disease/failure	Gastroesophageal reflux disease (severe)
Kidney insufficiency/failure	Esophageal or intestinal atresia
Cardiac cachexia	**Neurologic Impairment**
ARDS/ALI	Comatose state
Bronchopulmonary dysplasia	Cerebrovascular accident
Congenital heart disease	Demyelinating disease
Organ transplantation	Severe depression
Hypermetabolic States	Cerebral palsy
Closed head injury	**Other Indications**
Burns	AIDS
Trauma	Anorexia nervosa
Postoperative major surgery	Complications during pregnancy
Sepsis	Failure-to-thrive
	Geriatric patients with multiple chronic diseases
	Extreme prematurity
	Inborn errors of metabolism
	Cystic fibrosis

AIDS, acquired immune deficiency syndrome; ALI, acute lung injury; ARDS, acute respiratory distress syndrome.

Table 101–2

Contraindications and Precautions for EN
Severe hemorrhagic pancreatitis
Severe necrotizing pancreatitis
Necrotizing enterocolitis
Diffuse peritonitis
Small bowel obstruction
Paralytic ileus
Severe hemodynamic instability
Enterocutaneous fistulae
Severe diarrhea
Severe malabsorption
Severe GI hemorrhage
Intractable vomiting
Uncorrectable coagulopathy
Bowel ischemia

Enteral Versus Parenteral Feeding

PN by large central vein became popular in the 1960s. In the late 1980s and early 1990s clinical studies started demonstrating better clinical outcomes with EN compared to PN. Potential advantages of EN over PN are included here. First, EN is expected to preserve the gut barrier function better than PN. This could prevent translocation of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation, thus preventing infections. Some studies indicate **KEY CONCEPT** EN is associated with fewer infectious complications than PN. EN is cited frequently as having a better overall safety profile than PN, which is associated with more severe complications, such as pneumothorax and catheter sepsis. EN is associated with more nuisance complications, such as GI side effects. EN formulas typically are cheaper and less labor intensive to prepare than PN, although some specialty EN formulas approach the cost of PN formulas. Depending on the method of feeding tube placement, EN costs can mount if the tube must be placed by a radiologist or gastroenterologist.

Arguments in support of EN over PN have been questioned related to whether EN is beneficial compared with PN or whether PN as previously administered might have been detrimental. Overfeeding and hyperglycemia occur easily with PN, and the potential harm of hyperglycemia, especially in critical care populations, has been demonstrated, although the exact range optimal for glycemic control in ICU patients may differ for various critically ill subpopulations. PN historically led to increased infection risk and perhaps caused more harm than good in many instances unless patients were severely malnourished.[11] Whether EN truly prevents infections and improves clinical outcomes or PN is detrimental continues to be debated. Presently, most experts prefer EN over PN when the gut is functional. Use of PN to supplement EN during the first week of intensive care therapy when EN is not yet being tolerated at full rates is supported by European guidelines.[2] This is currently discouraged by American and Canadian ICU guidelines, although support is growing.[3,6] Randomized controlled trials relating to EN versus PN and deliberate (permissive) underfeeding (setting caloric goals below that necessary to achieve energy balance) have yielded disparate results.[12-20]

ROUTES OF ACCESS

There are several access sites for EN (Figure 101–2).[21,22] The feeding tube tip can end up in the stomach, duodenum, or jejunum. Advantages and disadvantages exist for each EN route (Table 101–3).

Gastric Feeding

Gastric feedings are commonly used. They require an intact gag reflex and normal gastric emptying for safety and success. Certain patients, such as those with head trauma, may not empty their stomachs efficiently and may not be good candidates for gastric feedings. Pooling of formula in the stomach could increase risk of aspirating feeding formula into the lungs.

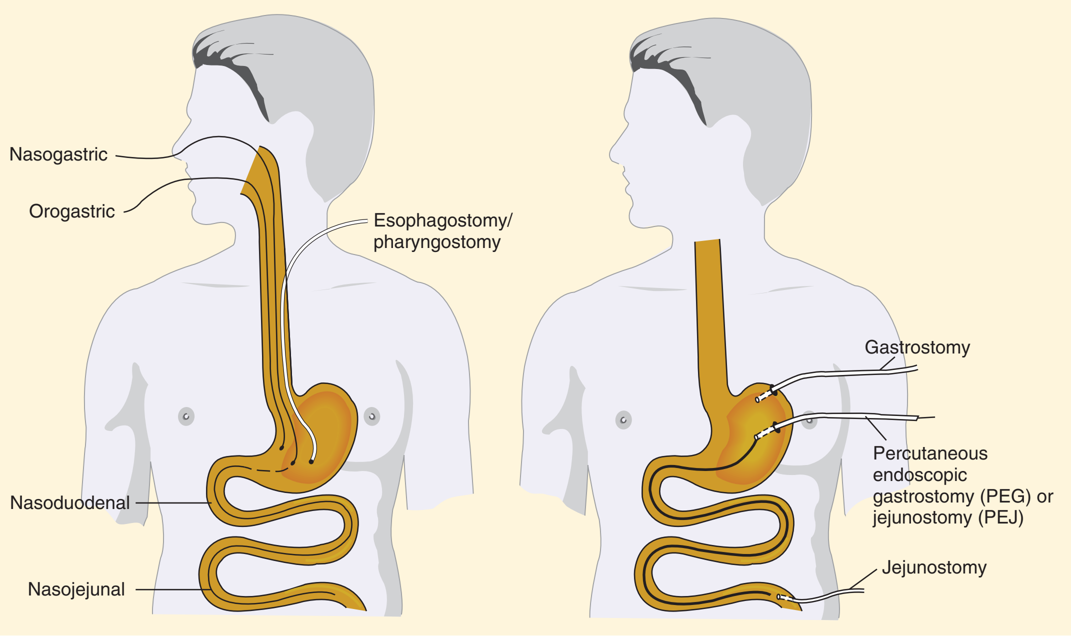

FIGURE 101–2. Access sites for tube feeding. (From Kumpf VJ, Mulherin DW. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 11th ed, New York, NY: McGraw-Hill; 2020; Figure 160–2.)

Table 101–3

Options and Considerations in the Selection of Enteral Access

Access	EN Duration/Patient Characteristics	Tube Placement Options	Advantages	Disadvantages
Nasogastric or orogastric	Short term Intact gag reflex Normal gastric emptying	Manually at bedside	Ease of placement Allows for all methods of administration Inexpensive Multiple commercially available tubes and sizes	Potential tube displacement Potential increased aspiration risk
Nasojejunal	Short term Impaired gastric motility or emptying High risk of GER or aspiration	Manually at bedside Fluoroscopically Endoscopically	Potential reduced aspiration risk Allows for early postinjury or postoperative feeding Multiple commercially available tubes and sizes	Manual transpyloric passage requires greater skill Potential tube displacement or clogging Bolus or intermittent feeding not tolerated
Gastrostomy	Long term Normal gastric emptying	Surgically Endoscopically Radiologically Laparoscopically	Allows for all methods of administration Low-profile buttons available Large-bore tubes less likely to clog Multiple commercially available tubes and sizes	Attendant risks associated with each type of procedure Potential increased aspiration risk Risk of stoma site complications
Jejunostomy	Long term Impaired gastric motility or gastric emptying High risk of GER or aspiration	Surgically Endoscopically Radiologically Laparoscopically	Allows for early postinjury or postoperative feeding Potential reduced aspiration risk Multiple commercially available tubes and sizes Low-profile buttons available	Attendant risks associated with each type of procedure Bolus or intermittent feeding not tolerated Risk of stoma site complications

EN, enteral nutrition; GER, gastroesophageal reflux.

From Kumpf VJ, Mulherin DW. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 11th ed. New York, NY: McGraw-Hill; 2020.

The nasogastric (NG) route is used most commonly for short-term enteral access. The major advantage is that the tube can be placed quickly and inexpensively by the bedside nurse.

Gastrostomy tubes, in which an incision is made directly through the abdominal wall, are indicated for patients who can tolerate gastric feedings but in whom a minimum of 4 weeks of feedings is anticipated. Most commonly, gastrostomy tubes are either placed percutaneously by interventional radiology or are percutaneous endoscopic gastrostomy (PEG) tubes placed endoscopically. Gastrostomy tubes also can be placed laparoscopically or during an open surgical procedure. Placement of a gastrostomy tube radioscopically, endoscopically, or surgically is more expensive than bedside orogastric (OG) or NG placement but can result in a larger-bore tube.

Postpyloric Feedings

KEY CONCEPT For patients intolerant of gastric feedings or in whom the risk of aspiration is high, feedings delivered with the tip of the tube in the jejunum are preferred. This bypasses the problem of poor gastric emptying and adds another barrier (pyloric sphincter) through which tube feedings must traverse before lung aspiration. However, postpyloric feedings do not preclude possible aspiration. Many patients aspirate their own oropharyngeal secretions.

Nasoduodenal and nasojejunal (NJ) feeding tubes can be placed by trained, experienced bedside nurses. Bedside electromagnetic transmitter devices (eg, CORTRAK, Corpak Medsystems) may be helpful in achieving postpyloric tube placement. In some institutions, ND or NJ placements are done in radiology by a radiologist using fluoroscopy to visualize tube advancement, increasing the cost of EN therapy. NJ tubes generally are preferred over ND tubes; placement of the tube tip distal to the ligament of Treitz may reduce risk of aspiration. Alternatively, during a laparotomy, the surgeon can place an ND or NJ tube.

Surgically placed jejunostomy tubes are placed through the abdominal wall. These tubes are sometimes placed during laparotomy following abdominal trauma. Alternatively, jejunal access can be obtained by placing a jejunal extension through a PEG tube; the resulting tube is sometimes referred to as a *PEGJ tube* or *G-J tube*. Another option is to place a percutaneous endoscopic jejunostomy (/PEJ) tube directly; this is more technically difficult and is not available in some institutions.

METHODS OF DELIVERY

Enteral feedings are delivered by several methods. Continuous infusion must be used when duodenal or jejunal feedings are administered; intermittent feedings directly into the small bowel generally result in GI intolerance. For gastric feedings, bolus or intermittent feedings could be administered instead of continuous feedings. Each method has advantages and disadvantages.

In hospitals, EN is usually delivered by continuous infusion at a constant rate regulated by an infusion pump. A variation of continuous infusion is cyclic feeding, in which a constant rate is maintained over a certain number of hours daily; this method of administration is used commonly in long-term care or home settings. Sometimes EN is administered overnight. Continuous feedings are often started at a low rate and titrated up every few hours as the patient tolerates. In the ICU, trophic feeding (very low rates of 10–20 mL/hour) is frequently utilized early in an ICU illness.

Intermittent feedings are used commonly in long-term care or home settings. Patients frequently start with continuous feedings; transition to intermittent feedings given several times a day over about 30 to 45 minutes for each feeding and eventually are changed to bolus feedings administered over less than 10 minutes per feeding. Intermittent feedings may be administered by gravity flow adjusted with a roller clamp, although some institutions may use an infusion pump. Bolus feedings can be administered using a 60-mL syringe, although sometimes an infusion set and pump may be used. Intermittent and bolus feedings often are given in amounts of 240 to 480 mL per feeding, corresponding to one to two cans of formula.

Some institutions have volume-based feeding protocols instead of rate-based. In these protocols, nurses have the latitude to increase the rate after the feeding has been held such that the prescribed volume is administered over a 24-hour period.

EN FORMULAS

One advantage of EN over PN is the availability in the United States of certain nutrients in some EN formulations (eg, glutamine) that are not available parenterally. Many EN formulas are marketed. Hospitals and long-term care facilities limit formularies of EN formulas, stocking only a limited number of products. Manufacturers' web sites should be consulted for the most current information on content of enteral formulas as changes do occur.

Polymeric Versus Oligomeric Formulas

A major criterion for categorizing EN products is whether macronutrients (particularly protein) are more intact (polymeric) or present in simpler forms (oligomeric). **KEY CONCEPT** Standard EN formulas are polymeric; these are appropriate for most patients. Oligomeric formulas should be reserved for patients with GI dysfunction.

Polymeric formulas typically contain intact proteins. They have low osmolality (300–500 mOsm/kg [mmol/kg]). These usually supply essential vitamins and minerals in amounts similar to the adequate intakes (AIs) or recommended dietary allowances (RDAs) when the formula is delivered in amounts adequate to meet macronutrient requirements. Most modern formulas are lactose and gluten free. Products designed for use as oral supplements generally are polymeric and often have sucrose or other simple sugars added to improve taste.

Oligomeric formulas are also known as *chemically defined formulas.* These can be subcategorized based on whether the formula contains all free amino acids (elemental formulas) or peptides (peptide based) as the protein source. Some formulas contain a combination of free amino acids and small peptides. Dipeptides and tripeptides are absorbed more efficiently than free amino acids. Oligomeric formulas may be better tolerated than polymeric formulas for patients with defects in GI function and may be particularly useful with severe pancreatic dysfunction. However, adaptation of the bowel is better when intact nutrients are supplied to patients with short bowel syndrome, so those patients should be transitioned to intact nutrients as soon as possible.

Oligomeric formulas typically are more expensive than polymeric formulas and have higher osmolality. However, osmolality of these products usually does not exceed 700 mOsm/kg (mmol/kg), a value less than that of many oral medications or a regular diet. If more fluid is required, extra water can be administered as boluses through the tube. If medications are administered through the tube, generous amounts of water should be used to flush the tube before and after each medication; this practice helps prevent tube occlusion.

Oligomeric formulas are less palatable than polymeric formulas and are not designed for use as oral supplements. Many oligomeric formulas provide some fat calories as medium-chain triglycerides (MCT), a fat source that is more readily absorbed and metabolized than long-chain triglycerides (LCTs) typically found in polymeric formulas. The MCTs do not require bile salts or pancreatic enzymes for absorption. Some elemental formulas contain a low proportion of fat (< 10% of total calories), which makes them useful in certain situations where fat needs to be restricted. The carbohydrate source in oligomeric formulas is less complex than in polymeric formulas.

Fiber Content

Another distinguishing factor of enteral formulas is whether they contain fiber. Both soluble and insoluble fibers may be included. Insoluble fiber exerts an effect on gut motility by drawing water into the intestine and speeding transit, preventing constipation. Soluble fiber can help to lower blood cholesterol levels, regulate blood sugar, and prolong gastric emptying. It may also help control diarrhea. Soy fiber provides primarily insoluble fiber, but also some soluble fiber, and is the most common fiber source in tube feeding products. Fiber has been useful for regulating gut motility in some clinical studies; it certainly can be useful in selected patients.[23] Some patients may experience GI discomfort secondary to gas production with introduction of fiber.

Fructooligosaccharides (FOS) are a form of soluble fiber that pass through the stomach and small bowel undigested and are fermented by colonic bacteria to the SCFAs butyrate, propionate, and acetate. The SCFAs serve as a fuel source for colonocytes and serve other important functions.[24] The FOS are thus prebiotics that serve as fermentable substrates for normal flora of the colon. The SCFAs are not added directly to EN products because they would be absorbed completely before reaching the colon; rather, FOS are added, allowing bacterial degradation to form SCFAs. Products containing FOS are often avoided postoperatively due to increased gas, bloating, and abdominal distention.

Caloric Density

Enteral feeding formulas can be categorized based on caloric density. Standard caloric density is 1 to 1.3 kcal/mL (4.2–5.4 kJ/mL). More calorically dense formulas containing 1.5 to 2 kcal/mL (6.3–8.4 kJ/mL) are available and have higher osmolality. Fluid-overloaded patients may benefit from more calorically dense formulas. As caloric content of a formula increases, the amount of free water decreases.

Protein Content

Protein content is an important factor in choosing an EN formula. Standard protein content in EN formulas is up to about 20% of total calories as protein. High-protein formulas containing 25% or more of total calories as protein are available for highly stressed patients with elevated protein needs. Low-nitrogen formulas containing less than 10% of total calories as protein for use in patients requiring protein restriction are also available. Protein in tube feeding ranges from about 35 to 95 g/L.

Carbohydrate Content

Common carbohydrate sources in tube feeding products include maltodextrin, corn syrup solids, and hydrolyzed cornstarch. Products containing simple sugars (often those intended for oral use) tend to be higher in osmolality.

Fat Content

Both MCTs and LCTs are used in tube feeding products. Corn, soy, sunflower, and safflower oils are standard sources of fat, providing mainly ω-6 polyunsaturated fatty acids (PUFAs). Some newer EN products contain higher quantities of ω-3 PUFAs from sources such as fish oil (ie, docosahexaenoic acid [DHA] and eicosapentaenoic acid [EPA]). Other formulas contain higher quantities of monounsaturated fatty acids (MUFAs) from canola oil and the high-oleic variety of certain oils (eg, safflower or sunflower). The essential fatty acid (EFA) content (mainly linoleic acid) of EN formulas is important because EFA deficiency can be induced if at least 1% to 4% of total calories are not supplied as EFAs. MCT oil does not contain EFAs.

Vitamin, Mineral, and Electrolyte Content

Most EN products contain vitamins and minerals, including major electrolytes, in amounts adequate to deliver the RDA or AI when a standard volume of formula is delivered daily. Some specialty formulas (eg, renal formulas) may have altered amounts of certain micronutrients.

Specialty Formulas

Specialty formulas designed for use in specific clinical situations generally are more expensive than standard polymeric formulas.

KEY CONCEPT Robust clinical trial data supporting use of specialty formulas in niche populations typically remain lacking in terms of improved patient outcomes.

Stress and Trauma Formulas

Historically, formulas aimed specifically for highly stressed, critically ill patients, were enriched with branched-chain amino acids (BCAAs). The rationale was that skeletal muscle BCAAs are preferentially used for energy in critical illness. Provision of BCAAs might limit breakdown of muscle in these patients. Clinical data failed to support or refute benefit of these formulas unequivocally in terms of clinical outcomes.

The newer generation of enteral feeding formulas marketed for use in these populations covers a broad spectrum of characteristics (Table 101–4). Whereas some are polymeric, others are oligomeric to address malabsorption that may accompany high stress. Some formulas marketed for use in critical illness are calorically dense (1.5–2 kcal/mL [6.3–8.4 kJ/mL]) to address fluid restrictions seen in this population, and others are less calorically dense. Most contain generous amounts of protein to address requirements of highly stressed patients. Many products contain ingredients purported to increase immune function; the term *immunonutrition* is sometimes attached to these products.

Immune-enhancing ingredients present in some enteral feeding products include arginine, glutamine, ω-3 fatty acids, nucleic acids, and antioxidants. Few products contain all of these (see Table 101–4). Arginine is an important substrate for nitric oxide (NO) synthesis, and small amounts of NO have beneficial effects on immune function under certain conditions. Arginine has been purported to have a positive influence on lymphocyte and macrophage function. Glutamine is considered conditionally essential

Table 101–4

Selected Adult Enteral Feeding Formulas Marketed for Use in Critical Illness, High Stress, Pulmonary Disease and Ventilator-Dependent, or Trauma Patients[a]

Product Name/Manufacturer	kcal/mL	Protein (g/L)	Protein (g/1000 kcal)	Enriched Ingredients[b]
Peptamen 1.5/Nestle	1.5	68	46	MCT
Nutren 2.0/Nestle	2	84	42	MCT

Vivonex Plus/Nestle	1	45	45	Glutamine, arginine
Vivonex RTF/Nestle	1	50	50	MCT[c]
Peptamen Intense VHP/Nestle	1	92	92	MCT, omega-3 FA
Perative/Abbott	1.3	67	51	MCT, arginine

[a] One kcal is equivalent to 4.184 kJ.

[b] Formula considered enriched if following criteria met: arginine—greater than 8.5 g/1500 kcal (6279 kJ); glutamine—greater than 9 g/1500 kcal (6279 kJ); MCT—greater than 30% of total fat; and ω-3 fatty acid—ratio of ω-6 to ω-3 less than or equal to 2:1 or greater than 1.5 g/L ω-3 fatty acids.

[c] Low-fat product.

CI, critical illness; EPA, eicosapentaenoic acid; FA, fatty acid; GLA, γ-linoleic acid; HS, high stress; MCT, medium-chain triglycerides; PD, pulmonary disease/ventilator dependent; TR, trauma

Table 101–5

Selected Adult Enteral Feeding Formulas Marketed for Use in Adult Diabetes and Stress-Induced Hyperglycemia[a]

Product Name/Manufacturer	kcal/mL	% kcal as Fat	% kcal as Carbohydrate	Fiber (g/L)
Glytrol/Nestle	1	43	40	15
Glucerna 1.0 Cal/Abbott	1	49	34	14
Glucerna 1.2 Cal/Abbott	1.2	45	38	16
Glucerna 1.5 Cal/Abbott	1.5	45	35	16
Diabetisourse AC/Nestle	1.2	53	33	15

[a] One kcal is equivalent to 4.184 kJ.

in critical illness and is a preferred fuel source for enterocytes. Supplementation with glutamine, either parenterally or enterally, may help maintain integrity of gut mucosa, preventing translocation of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation. However, glutamine supplementation remains controversial.[3,6,25,26] The ω-3 fatty acids, primarily from fish oils, are included in many immunonutrition products. Metabolites of ω-6 fatty acids include mediators such as prostaglandins, leukotrienes, and thromboxanes that are primarily proinflammatory and increase coagulation. Conversely, mediators produced from ω-3 fatty acids are less proinflammatory and decrease coagulation. Limited data support nucleic acids as immunomodulators. Quantities of antioxidants (particularly vitamin C, vitamin E, and β-carotene) higher than traditionally found in standard enteral formulas are added to some immunonutrition formulas to protect body systems, including the immune system, from damage by oxygen-free radicals. **KEY CONCEPT** Use of enteral immunonutrition in certain clinical settings is widely accepted. Commercial immunonutrition products and/or specific ingredients found in these products have generally been found to have no benefit in terms of mortality rates.[3,27,28] However, infection rates, length of stay, and length of time on a ventilator may be decreased with these products. The 2016 ASPEN/SCCM ICU guidelines support use of these formulas in traumatic brain injury and surgical ICU patients but not in medical ICU patients.[6] The best timing (initiation and duration) of delivery remains to be determined.

Pulmonary Formulas

Enteral feeding formulas designed for use in patients with chronic obstructive pulmonary disease or receiving mechanical ventilation contain higher amounts of fat (40%–55% of total kilocalories) than most formulas. The rationale is that burning fat for energy is associated with less carbon dioxide production compared with burning of carbohydrate, which would be advantageous in patients with retention of this substance and might facilitate weaning from mechanical ventilation. Because part of the market targeted by the manufacturers of these products comprises mechanically ventilated patients, these products are included in Table 101–4. At conservative calorie levels, standard enteral formulas usually can be given without fear of excess carbon dioxide production.

Oxepa (Nestle) has been studied specifically in critically ill patients with acute respiratory distress syndrome (ARDS), acute lung injury (ALI), and sepsis. This formula contains high quantities of the ω-3 fatty acids EPA and γ-linolenic acid (GLA). GLA is metabolized to a prostaglandin with vasodilatory properties, whereas EPA is converted to prostaglandins and leukotrienes that are less proinflammatory than those derived from ω-6 fatty acids. This formula contains large quantities of antioxidants. Whereas the Canadian guidelines state that use of this formula should be considered in ALI and ARDS, the 2016 ASPEN/SCCM critical care guidelines do not endorse it.[3,6]

Diabetic Formulas

Like pulmonary formulas, formulas for patients with diabetes or stress-induced hyperglycemia are relatively high in fat and low in carbohydrates (Table 101–5). They typically contain fiber (primarily soluble) because it plays some role in glycemic control, and they may contain fructose and MUFAs. Data support improved blood sugar control with use of these formulas in patients with diabetes.[29] Whether or not a diabetic EN formula is chosen, avoidance of overfeeding and maintenance of good glycemic control with insulin or other hypoglycemic medications are important.

Renal Formulas

Products designed for use in renal failure have high caloric density (1.8–2 kcal/mL [7.5–8.4 kJ/mL]) to decrease administered fluid (Table 101–6). They vary in amounts of nutrients, such as protein, potassium, phosphorus, and magnesium. Products low in protein (20–35 g/L) may be appropriate in chronic renal failure patients not yet receiving dialysis. On the other hand, removal of nitrogen by dialysis, coupled with the hypercatabolic, hypermetabolic condition seen in many acute renal failure patients, makes use of higher-protein formulas (80–90 g/L) appropriate in these situations. Potassium, phosphorus, and magnesium contents of EN formulas designed for use in renal failure tend to be lower than standard formulas because these renally excreted electrolytes accumulate during renal failure.

Historically, enteral formulas designed for renal failure were enriched with essential amino acids (EAAs) and contained lesser amounts of nonessential amino acids (NEAAs) than standard formulas. Theoretically, EAAs could combine with urea nitrogen in the synthesis of NEAAs, leading to a decrease in blood urea nitrogen (BUN). The only situation in which such formulas may be appropriate is in patients with chronic renal failure who are not candidates for dialysis. Even in this setting, use of these products should be limited to no more than 2 or 3 weeks. These formulas have been supplanted largely by polymeric formulas with protein content similar to standard EN formulas. Many dialysis patients tolerate standard, high-protein EN formulas, although electrolytes must be monitored closely.

Hepatic Formulas

Specialized formulas for patients with hepatic insufficiency are limited in number. These are enriched with BCAAs while containing a reduced quantity of aromatic amino acids (AAAs) and methionine compared with standard formulas. These changes

Table 101–6

Selected Adult Enteral Feeding Products Designed for Use in Renal Failure

Product Name/Manufacturer	Protein/L	Protein (g/1000 kcal[a])	Characteristics
Nepro with Carb Steady/Abbott	80	45	Complete formula[b] for patients on dialysis
Novasource Renal/Nestle	91	46	Complete formula for patients with CKD or AKI on dialysis
Suplena with Carb Steady/Abbott	45	25	Complete formula with low amounts of protein for patients not on dialysis
Renacal/Nestle	34	17	For patients with AKI and severe electrolyte restriction not on dialysis

CKD, chronic kidney disease; AKI, acute kidney injury.

[a] One kcal is equivalent to 4.184 kJ.

[b] Complete formula—contains all nutrients in amounts sufficient to meet needs of most patients in a volume equal to or less than that usually administered.

address high levels of AAAs and low levels of BCAAs found in the blood of patients with hepatic insufficiency. Theoretically, they might help patients with hepatic encephalopathy (HE). Improvement in outcomes with short-term therapy with these products has not been consistent.[6] An example of a specialized hepatic formula is Hepatic-Aid II (Hormel Health Labs), a product supplied as a powder for reconstitution that requires vitamin, mineral, and electrolyte supplementation. A second product is NutriHep (Nestle), supplied as a liquid formula containing the recommended amounts of key vitamins, minerals, and electrolytes.

The ASPEN/SCCM guidelines for the ICU recommend against the use of protein restriction to reduce risk of development of HE.[6] These guidelines recommend use of standard EN formulas for ICU patients with acute or chronic liver disease.

Wound Healing Formulas

Tube feeding and oral supplement formulas designed for use in patients with wounds or decubitus ulcers typically supply high amounts of protein and calories. The antioxidant vitamins A, C, and E are frequently also found in high quantities as is zinc.

Patient Encounter, Part 1

TR is a moderately thin 70-year-old woman with a history of smoking and type 2 diabetes mellitus. She is admitted to the hospital with severe shortness of breath requiring mechanical ventilation. Her husband reports that she has not been feeling well for the past week, and he estimates that she has lost at least 5 lb (2.3 kg). Her COVID-19 test is positive. She requires vasopressor therapy for blood pressure maintenance and develops acute kidney injury. She is started on propofol for sedation while on the ventilator and is placed in the prone position for multiple hours each day due to an acute respiratory distress syndrome picture. Her dry weight is 60 kg (133 lb); height is 68 in (173 cm); body mass index is 20 kg/m^2.

When should EN be attempted in this patient?

What initial regimen of EN should be attempted?

What would appropriate caloric and protein goal ranges be for this patient?

Modular Components

Single nutrient components are frequently administered through feeding tubes to augment the composition of the EN formula. Protein modules are probably most used. These may be supplied as a liquid product or as a powder that must be reconstituted with water. Another modular component is fiber. These are typically given as a bolus through the feeding tube rather than being added to the feeding formula.

MONITORING AND COMPLICATIONS

Although EN complications are generally less serious than those of PN, some can be dangerous or can lead to impaired delivery of desired nutrient load. Complications can be divided into four categories: GI, technical, infectious, and metabolic. The first three categories, along with common causes, are listed in Table 101–7. Patients on EN must be monitored for prevention of complications (Table 101–8). Monitoring of many parameters can become less frequent as the patient's condition stabilizes. Monitoring for efficacy of EN is also important.

GI Complications

KEY CONCEPT GI complications are the most common complications of EN limiting the amount of feeding that patients receive. Although diarrhea frequently is blamed on feeding formula or method of EN administration, other possible causes usually exist (see Table 101–7). In the inpatient setting, patients receiving EN frequently are very sick. *Clostridioides difficile* colitis must be considered as a possible cause of diarrhea, especially in patients receiving antimicrobial therapy or proton pump inhibitors.[30] A medication-related cause of diarrhea is the sorbitol content of medications. Large quantities of sorbitol present in oral liquid medications can cause diarrhea.[31] Unfortunately, sorbitol content of many medications is not listed on their labeling, and manufacturers frequently reformulate preparations to contain varying amounts of excipients, such as sorbitol.

Determining cause of diarrhea is important to determine how to address the problem. Whereas *C. difficile* colitis should be treated with an appropriate antibiotic, medication-related diarrhea can be addressed by removal of the offending agent. Likewise, diarrhea secondary to malabsorption sometimes can be addressed by changing to an oligomeric EN formula. Antiperistaltic agents (eg, loperamide) may be useful in some noninfectious diarrhea.

Table 101–7

Complications of Tube Feeding

Complication	Causes
GI	
Diarrhea	Drug related Antibiotic-induced bacterial overgrowth Hyperosmolar medications administered via feeding tubes Antacids containing magnesium Excipients (eg, sorbitol) Malabsorption Hypoalbuminemia or gut mucosal atrophy Pancreatic insufficiency Inadequate GI tract surface area Rapid GI tract transit Radiation enteritis Tube feeding related Rapid formula administration Formula hyperosmolality Low-residue (fiber) content Lactose intolerance Bacterial contamination
Nausea and vomiting	Gastric dysmotility (surgery, anticholinergic drugs, diabetic gastroparesis) Rapid infusion of hyperosmolar formula
Constipation	Dehydration Drug induced (anticholinergics) Inactivity Low-residue (fiber) content Obstruction or fecal impaction
Abdominal distention or cramping	Too rapid formula administration
Technical	
Occluded feeding tube lumen	Insoluble complexation of enteral formula and medication(s) Inadequate flushing of feeding tube Undissolved feeding formula
Tube displacement	Self-extubation Vomiting or coughing Inadequate fixation (jejunostomy)
Aspiration	Improper patient position Gastroparesis or atony causing regurgitation Feeding tube malpositioned Compromised lower esophageal sphincter Diminished gag reflex
Peristomal excoriation	Improper skin and tube care GI tract secretions leaking peristomally
Infectious	
Aspiration pneumonia	Same as technical—aspiration comments Prolonged use of large-bore polyvinylchloride tube

GI, gastrointestinal.

From Janson DD, Chessman KH. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 5th ed. New York, NY: McGraw-Hill; 2005.

On the other hand, constipation may occur in patients receiving EN, especially the elderly. Increased provision of fluid or fiber may be useful. Constipation may be drug related, in which case discontinuation or replacement of the offending drug may be beneficial.

Table 101–8

Suggested Monitoring for Patients on Enteral Nutrition

Parameter	During Initiation of EN Therapy	During Stable EN Therapy
Vital signs	Every 4–6 hours	As needed with suspected change (ie, fever)
Clinical assessment		
Weight	Daily	Weekly
Total intake/output	Daily	As needed with suspected changed in intake/output
Tube feeding intake	Daily	Daily
Enterostomy tube site assessment	Daily	Daily
GI tolerance		
Stool frequency/volume	Daily	Daily
Abdomen assessment	Daily	Daily
Nausea or vomiting	Daily	Daily
Gastric residual volumes	Every 4–8 hours (varies)	As needed when delayed gastric emptying suspected
Tube placement	Prior to starting; then ongoing	Ongoing
Laboratory		
Electrolytes, blood urea nitrogen/serum creatinine, glucose	Daily until stable, then 2–3 times per week	Every 1–3 months
Calcium, magnesium, phosphorus	Daily until stable, then 2–3 times a week	Every 1–3 months
Liver function tests	Weekly	Every 1–3 months
[a]Trace elements, vitamins	If deficiency/toxicity is suspected	If deficiency/toxicity is suspected

[a]Most tests for monitoring trace elements and vitamins are unreliable when an inflammatory response is present, and signs, symptoms, and risk factors should determine the need for supplementation unless accurate monitoring parameters are available.

EN, enteral nutrition.

From Kumpf VS, Mulherin DW. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 11th ed. New York, NY: McGraw-Hill; 2020.

Impaired gastric emptying is seen commonly in EN patients receiving gastric feedings and may be associated with nausea and vomiting. Impaired emptying may be related to disease process (eg, diabetic gastroparesis or sequelae to head injury) or to drug therapy, most notably narcotics. Gastric residual checks frequently are measured in patients receiving gastric feedings (see Table 101–8). The 2016 ASPEN/SCCM critical care guidelines recommend against routine gastric residual check and suggest that, if such checks are performed, feedings should not be held for residual volumes less than 500 mL in absence of other signs of intolerance.[6] Approaches to the patient with delayed gastric emptying might include changing to a formula containing less fat because dietary fat is associated with slower gastric emptying. Metoclopramide often is given to patients receiving gastric feedings to facilitate gastric emptying. Erythromycin is an alternative that may be useful, although it is associated with drug–drug interactions. Patients with poor gastric emptying may be at higher risk of aspirating feedings into their lungs and should be considered for transition to postpyloric feedings. Postpyloric feedings may help relieve EN-related nausea and vomiting and are preferred for patients without an intact gag reflex. An important practice to help prevent aspiration is elevation of the head of the bed to at least 30 degrees during continuous feedings as well as during and for 30 to 60 minutes after intermittent and bolus feedings. Prone positioning (ie, placing the patient on the stomach) in conditions such as ARDS seen in severe COVID-19 is not a contraindication for EN.

Technical Complications

Technical or mechanical complications are encountered frequently in EN patients. Tube occlusion most commonly is related to formula occlusion or medication administration through the tube.[32] **KEY CONCEPT** An important practice to help prevent medication-related occlusion is adequate water flushing of the tube before, between, and after each medication administration. If intermittent feedings are used, water flushing after each feeding is recommended. Clearing of occlusions using water or pancreatic enzymes plus sodium bicarbonate can be attempted, and special devices and kits are available.[4,32]

Tube displacement is a potentially significant complication. This may be seen in an agitated patient pulling at the tube, or the tube tip may migrate spontaneously. If the tip of the tube is positioned in the tracheobronchial tree and feeding is delivered to this area, pneumonia, pneumothorax, and other problems could potentially occur. Location of the tip of the feeding tube (eg, nasogastric) may be confirmed by chest radiograph or, perhaps, ultrasound. For ongoing assessment of tube placement, auscultation and measurement of aspirate pH can be utilized.

Endoscopic and surgical feeding tubes can cause erosion of the exit site due to leakage of gastric or intestinal contents onto the skin. This complication must be addressed by good wound care and repair or replacement of the access device. Similarly, NG, ND, and NJ tubes can be complicated by nasopharyngeal irritation or necrosis. This is one reason why such tubes should be considered for short-term use only.

Infectious Complications

Infectious complications of EN include aspiration pneumonia and infections related to delivery of contaminated EN formula. Although GI infections owing to industrial contamination of enteral formulas have been reported uncommonly, formulas are more commonly seeded with organisms during the processes of transferring from can to delivery bag or during the process of reconstitution of powdered formulas. So-called closed systems of delivery, wherein the formulas come from the manufacturer premixed in a delivery bag, should help decrease possibility of formula contamination.

Metabolic Complications

Metabolic complications of EN most commonly include disorders of fluid and electrolyte homeostasis and hyperglycemia. More severely ill patients require more frequent monitoring (see Table 101–8). Both dehydration and fluid overload can occur. Careful monitoring of fluid inputs and outputs as well as body weight is important. Dehydration may be caused by either excessive fluid losses or inadequate fluid intake. The trend in the ratio of BUN to serum creatinine can be useful in helping monitor fluid status; a ratio greater than 15:1 (60:1 for SI mmol/L:mmol/L) may be an indicator of dehydration. High ratios may also be a result of high-protein provision by the feeding. Attention should be paid to free-water content of EN formulas. Free-water content varies from about 70% to 85%; percentage free water typically drops as caloric density of the formula rises. If dehydration develops, switching to a less calorically dense formula or using larger water flushes is appropriate. Fluid overload is reflected by increases in weight, lower extremity edema, and pulmonary rales and particularly may be a problem in patients with renal or cardiac insufficiency. Use of a more calorically dense EN formula may be helpful, and diuretic therapy may be necessary. Fluid imbalances often are associated with abnormalities of sodium homeostasis that should be addressed in concert with fluid imbalance.

Hypokalemia, hypomagnesemia, and hypophosphatemia are some of the most common electrolyte abnormalities in sick, hospitalized patients. These can occur in context of the refeeding syndrome, which may be seen in chronically malnourished patients aggressively started on feeding. Careful monitoring of electrolytes, coupled with a feeding regimen increased gradually to goal rate over a period of several days, should help protect at-risk patients from this complication. Hypokalemia and hypomagnesemia also are associated with excessive losses through the GI tract or urine and are associated with various medications, including diuretics. Repletion may be accomplished enterally in asymptomatic patients or parenterally if the patient is symptomatic or the abnormality is severe. Enteral repletion with magnesium and phosphate can cause diarrhea. Hyperkalemia, hypermagnesemia, and hyperphosphatemia are less common and usually are associated with renal insufficiency. Hyperkalemia also is associated with medications, including potassium-sparing diuretics, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers.

Although hyperglycemia is less common with EN than PN, it can occur. Many severely ill patients (eg, septic, highly stressed) receiving EN have a metabolic milieu promoting hyperglycemia. For ICU patients with hyperglycemia receiving continuous EN, an IV insulin drip may be the most effective way to achieve good glycemic control. Scheduled intermediate- or long-acting insulin plus nutritional and correctional regular- or rapid-acting insulin can be utilized after stabilization on the feeding regimen or for patients in whom insulin drips are not feasible.[33] Administration of a higher fat, lower carbohydrate EN formula may be useful in selected patients.

Monitoring for Efficacy and Outcome Evaluation

A useful physical measurement of EN efficacy in the long-term patient is body weight. Depending on the clinical situation, the goal may be weight gain, weight maintenance, or weight loss. Whereas day-to-day fluctuations in weight generally reflect fluid changes, week-to-week variations are more useful in determining if caloric provision is appropriate.

The amount of EN administered is often less than the amount ordered owing to interruptions in therapy. It is imperative to monitor volume of feedings actually received and to make adjustments in rates or amounts of EN as necessary.

Biochemical markers have been used historically to help interpret EN adequacy. Use of visceral proteins such as albumin or prealbumin is limited by the effects of inflammation on serum levels of these biomarkers.[34] In the acute phase of illness characterized by a proinflammatory state, proteins known as *acute-phase reactants* are preferentially synthesized. One of these measured clinically is C-reactive protein (CRP). In some patients with significant illness, prealbumin may not rise, even though the patient is receiving appropriate EN, until CRP begins to fall.

Patient Encounter, Part 2

On day 5, vasopressor requirements are minimal, but feeding via nasogastric tube has only been able to be advanced to one-quarter of goal rate. Propofol is changed to dexmedetomidine on day 5.

Why is it important to monitor triglycerides in this patient?

Should a postpyloric tube be placed in this patient, or would supplemental PN be more appropriate?

What is refeeding syndrome, and is this patient at risk for it? If so, how could it be prevented?

Collection of urine to calculate nitrogen balance can help analyze adequacy of caloric and protein provision.

In patients with wounds (eg, decubitus ulcers, surgical wounds), a goal of therapy is to facilitate wound healing. Monitoring status of the wound becomes part of ongoing nutritional assessment. In debilitated patients, particularly on long-term EN, measures of functional status such as grip strength and ability to perform activities of daily living become important components of nutritional assessment.

MEDICATION ADMINISTRATION IN PATIENTS RECEIVING EN

Medication Administration Through Feeding Tubes

If a patient receiving EN is alert and can swallow oral medications, then medications should be given by mouth. Many patients are not able to receive medications by this route, and the feeding tube may be considered as a delivery route. Effects of medication administration through feeding tubes on the delivery of both the drug and the EN formula nutrients have been inadequately studied.[35,36]

KEY CONCEPT Compatibility of medication with EN formula is of concern when administering medications through feeding tubes. An important technical complication of EN is tube occlusion, related most commonly to medication administration. Not only must compatibility of medication and EN formula be considered, but interactions between medications and the feeding tube itself must be considered. Strict protocols for flushing the tube before, between, and after administration of medications are important.[4] The best fluid for flushing is warm water. At least 15 mL of water should be used as a flush before and after medication administration through a feeding tube. Medications should be administered one at a time sequentially rather than being mixed together for simultaneous administration down the tube; ideally 15 mL of water should be used as a flush between medications. This should help prevent interactions between drugs within the tube itself that could lead to occlusion.

Different dosage forms present unique challenges for administration through feeding tubes. Certain solid dosage forms should not be crushed because crushing would alter release characteristics.[37] For example, controlled-release, extended-release, and sustained-release preparations should not be crushed, nor should sublingual dosage forms. Enteric-coated dosage forms generally are designed to protect acid-labile medications from stomach acid; when these dosage forms reach the small bowel with its higher pH, the drug is released into an environment in which it is more stable. Alternatively, enteric-coated dosage forms protect the stomach from medications that could cause irritation. Thus, crushing the enteric coating defeats the purpose of the dosage form and could lead to decreased efficacy or increased adverse events when administered down a gastric tube.

Medications available commercially as compressed tablets can generally be crushed for administration through tubes. After crushing, the fine powder should be mixed with 10 to 30 mL of fluid (usually warm water) for administration. A powdered dosage form inside a hard-gelatin capsule can be poured out and mixed with water for administration through tubes. Soft-gelatin capsules can be dissolved in warm water. Some enteric-coated and delayed-release microencapsulated products can be opened and individually coated particles administered through the tube without crushing if the tube has a large enough diameter.

If a liquid dosage form of a medication exists, it would seem rational to use this for administration through a feeding tube. This may decrease potential for tube clogging but may decrease tolerability of medication administration. Sorbitol is an excipient found in many liquid medications in amounts sufficient to cause diarrhea.

Another potential problem with administration of liquid medications through feeding tubes is high osmolality of some products. Dilution of hypertonic medications with 30 to 60 mL of water or administration of smaller dosages more frequently may help prevent diarrhea. Although administration of IV medications through feeding tubes may be entertained, these dosage forms frequently are hypertonic and contain problematic excipients when given via the GI tract.

It is generally not recommended to mix medications directly into EN formula because physical incompatibilities might lead to tube occlusion. It would seem logical that medications considered better absorbed in the fasted state either should be given between feedings on an intermittent feeding schedule, or feedings should be held before and after medication administration. However, not all studies have supported this idea, therefore this issue deserves further study.

Location of feeding tube tip is important when considering medication administration. This is particularly true if the medication acts locally in the GI tract. For example, sucralfate and antacids act locally in the stomach; administration through a duodenal or jejunal tube is illogical. For medications requiring acid for best absorption, administration directly into the duodenum or jejunum may result in suboptimal absorption. Absorption of drugs when administered directly into the small bowel, especially the jejunum, is a topic where more research would be useful.

Problem Medications

▶ *Phenytoin*

Certain medications present challenges when administered through feeding tubes. The medication studied most thoroughly is phenytoin. Most studies have shown significant decreases in phenytoin absorption when administered enterally to patients receiving EN. Several mechanisms have been proposed. Liberal dilution of phenytoin suspension before its administration down the tube may improve delivery. Many institutions hold tube feedings for 1 or 2 hours before and after administration of phenytoin, although some EN patients subjected to this routine still require high dosages to achieve therapeutic serum concentrations. Holding feeding around medication administration can make meeting nutritional requirements difficult with continuous feedings, especially if phenytoin is administered several times daily. Diligent monitoring of serum concentrations is necessary for the patient on EN receiving this medication. In some cases, use of IV phenytoin or another anticonvulsant may be prudent.

▶ *Warfarin*

EN formulas contain vitamin K, which can antagonize the pharmacologic activity of warfarin. Vitamin K content of EN formulas has been adjusted down over several decades, resulting in products that contain amounts of vitamin K unlikely to affect anticoagulation by warfarin significantly. However, inadequate warfarin anticoagulation in EN patients receiving formulas containing minimal vitamin K has been reported. A component of certain tube feedings, perhaps protein, may bind warfarin and result in suboptimal activity, as might the feeding tube itself. One small study indicated a better response in terms of the international normalized ratio (INR) when feedings were held for 1 hour before and after warfarin compared with administration of the drug without holding feedings.[38] When tube feedings are started, changed, or discontinued, INR should be monitored closely. Alternatively, a different oral anticoagulant may be considered.

▶ *Fluoroquinolones*

Absorption of antimicrobial agents, such as fluoroquinolones and tetracyclines, that can be bound by divalent and trivalent cations potentially could be compromised by administration with EN formulas containing these cations. Fluoroquinolones (eg, levofloxacin and ciprofloxacin) have been best studied in this regard, and results of studies are not consistent.[39] Some institutions hold tube feedings for 1 to 2 hours or more before and after enteral dosages of fluoroquinolones. Not all fluoroquinolones are affected by the interaction, suggesting that a mechanism other than chelation by divalent cations may also be significant.

Patient Encounter, Part 3

Supplemental PN is initiated on day 6, and trophic gastric feedings are continued. By day 10, advancement of the gastric feeding to goal rate is achieved, and PN is discontinued. TR is extubated on day 13. Concern regarding her swallowing strength leads to a speech pathology consult. On day 14 an order to advance oral diet as tolerated is written following the speech pathology assessment.

How should the transition from EN to oral feedings be accomplished?

A FEW NOTES ABOUT PEDIATRIC PATIENTS

Although many of the principles outlined in this chapter primarily geared toward adults receiving enteral nutrition would be similar in pediatrics, younger patients present challenges that sometimes necessitate a slightly different approach.[40-42] Younger pediatric patients and prematurely born infants have fewer nutritional reserves and are therefore at more risk for malnutrition. Like adults, if nutrition support is deemed necessary, the enteral route is preferred over parenteral.

Common pediatric scenarios leading to the use of EN due to unsafe or impractical oral intake include neurologic impairment,

Patient Care Process

Collect the Information:

- Based on patient's disease states and severity, estimate the amount of time until adequate oral intake resumes (Table 101–1).
- Are there any contraindications or precautions regarding use of EN (Table 101–2)? When the GI tract is nonfunctional, either PN or no SNS is indicated.
- If inadequate intake has occurred or is anticipated for 7 or more days, start SNS. The threshold for starting SNS is lower for previously malnourished patients. Critically ill patients at high nutritional risk should generally be started on EN within 24 to 48 hours of ICU admission.
- Choose the appropriate type of enteral access device based on expected duration of use and whether any condition exists which precludes gastric feeding (Table 101–3).
- Choose the method of feeding administration (eg, intermittent or continuous) based on feeding location (ie, gastric vs postpyloric) and other patient factors.

Assess the Information:

- Estimate calorie, protein, and fluid goals based on patient parameters.
- Are medications being administered down the feeding tube? If so, assess the appropriateness of this route.

Develop a Care Plan:

- Choose an appropriate tube feeding formula that best matches patient characteristics and estimated nutritional needs.
- Start tube feeding at full strength and increase rate as tolerated to goal that will meet patient's nutritional requirements.
- Develop plan to include monitoring at appropriate intervals for metabolic, GI, technical, or infectious complications (Table 101–8).
- Develop monitoring plan for adequacy of nutritional regimen. This may include serial weights, intakes and outputs, and measures of functional status.

Implement the Care Plan:

- If patient is to be discharged home on EN, educate patient or caregiver on enteral access device care, feeding delivery, troubleshooting, and complications to observe for and who should be contacted when complications occur (Table 101–7).

Follow-up: Monitor and Evaluate:

- Adjust formula, rate of administration, and/or route of administration if intolerance develops or nutritional goals (eg, weight loss, weight maintenance, weight gain, maintenance of muscle mass, slowing of functional decline) are not met.

neuromuscular disorders, genetic and metabolic disorders, prematurity, congenital abnormalities involving the GI tract, and other obstructive or injurious conditions or accidents to the oral cavity and GI tract. As in adults, EN is also used in critical illness due to accidents, infections, or other causes. Long-term EN becomes necessary for some children with neurologic impairment. Sometimes supplemental EN is utilized in children who can eat but are nevertheless malnourished, such as in patients with cystic fibrosis.

The routes of EN administration in children are similar to those used in adults and include NG, OG, and NJ for short-term use and PEG, PEJ, and surgically placed tubes for long-term EN. As in adults, usually either a bolus or continuous method of feeding is chosen. In children, these two modalities are sometimes combined, with small bolus feedings given during the day and continuous feedings at night to improve feeding tolerance.

Monitoring parameters in children on longer-term EN must measure growth. In addition to monitoring of weight as in adults, weight as well as length and head circumference are compared to growth charts to delineate trajectories of growth.

Feeding tubes used in infants and young children are typically very small in diameter, making medication administration down these tubes particularly challenging. Concentrations of standard pediatric formulas are lower than those of adults at 0.8 kcal/mL (20 kcal/oz or 3.3 kJ/mL). The reader is referred to specialized references for a more detailed discussion of pediatric tube feeding.[40-42]

SUMMARY AND CONCLUSION

EN is an important method of feeding patients who cannot or should not eat enough to meet nutrient requirements for a prolonged time. When the GI tract can be used safely, EN is preferred over PN. Various types of enteral access devices are available. Whereas tubes inserted through the nose often are adequate for patients expected to receive EN for a short time, devices that are more permanent are preferred for longer-term patients. The choice of whether to feed into the stomach or postpylorically is patient specific. Although numerous EN formulas are available, many products are very similar, making a limited formulary feasible. Data supporting many specialized types of EN formulas are limited. Although complications of EN tend to be less serious than those of PN, adverse effects encountered can be significant, and ongoing monitoring is necessary. Although medications can be administered through feeding tubes, various factors must be considered in each individual patient.

Abbreviations Introduced in This Chapter

ALI	Acute lung injury
AI	Adequate intake
AAA	Aromatic amino acid(s)
ARDS	Acute respiratory distress syndrome
ASPEN	American Society for Parenteral and Enteral Nutrition
BCAA	Branched-chain amino acid(s)
BUN	Blood urea nitrogen
CRP	C-reactive protein
DHA	Docosahexaenoic acid
EAA	Essential amino acid(s)
EFA	Essential fatty acid(s)
EN	Enteral nutrition
EPA	Eicosapentaenoic acid
ESPEN	European Society for Clinical Nutrition and Metabolism
FOS	Fructooligosaccharide
GALT	Gut-associated lymphoid tissue
GI	Gastrointestinal
GLA	γ-Linolenic acid
HE	Hepatic encephalopathy
IBD	Inflammatory bowel disease
ICU	Intensive care unit
INR	International normalized ratio
LCT	Long-chain triglyceride
MCT	Medium-chain triglyceride
MUFA	Monounsaturated fatty acid
ND	Nasoduodenal
NEAA	Nonessential amino acid
NG	Nasogastric
NJ	Nasojejunal
NO	Nitric oxide
OG	Orogastric
PEG	Percutaneous endoscopic gastrostomy
PEJ	Percutaneous endoscopic jejunostomy
PN	Parenteral nutrition
PUFA	Polyunsaturated fatty acid
RDA	Recommended dietary allowance
SCFA	Short-chain fatty acid
SCCM	Society for Critical Care Medicine
SNS	Specialized nutrition support

Overweight and Obesity

April Smith

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the underlying causes of overweight and obesity.
2. Identify parameters used to diagnose obesity and indicate the severity of disease.
3. Identify desired therapeutic goals for patients with obesity.
4. Recommend appropriate nonpharmacologic and pharmacologic therapeutic interventions for overweight or obese patients.
5. Implement a monitoring plan that will assess both the efficacy and safety of therapy initiated.
6. Educate patients about the disease state and associated risks, comprehensive lifestyle interventions, drug therapy, and surgical options necessary for effective treatment.

INTRODUCTION

Overweight and obesity are terms used to describe weight measurements greater than what is considered healthy for a given height.[1] KEY CONCEPT Body mass index (BMI), waist circumference (WC), comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients. BMI should be used to identify adults at increased risk for cardiovascular disease (CVD) and other obesity-related disorders. Evaluation of the patient's risk status involves not only calculation of the BMI but also the measurement of waist circumference. KEY CONCEPT The presence of comorbidities (CVD, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose) requires identification and aggressive management for overall effective treatment of the overweight or obese patient to reduce their risk of mortality. Obesity contributes to some of the leading causes of preventable death including hypertension, dyslipidemia, diabetes mellitus, CVD, stroke, sleep apnea, gallbladder disease, osteoarthritis, and certain cancers.[2] Obesity is officially recognized as a disease by the American Medical Association with a pathophysiological basis for metabolic and biochemical dysfunctions.

ETIOLOGY AND EPIDEMIOLOGY

Obesity is a multifactorial, complex disease that occurs because of an interaction between genotype and the environment. Although the etiology is not completely known, it involves overlapping silos of social, behavioral, hormonal, and genetic influence.[3] The majority of overweight or obese individuals are adults, but obesity is also prevalent in children between 2 and 19 years of age. Just over one-third of US adults 20 years of age and older are currently considered obese. The prevalence of obesity in men and women of various racial and ethnic origins differ. Thirty-six percent of non-Hispanic White adults are obese, where approximately 40% of Hispanics and 50% of non-Hispanic Black adults are obese.[4]

Thirty-two percent of children and adolescents aged 2 to 19 years are overweight or obese. Overweight children typically become overweight adults, but most obese adults were not overweight as children.[5] Psychosocial functioning also may be hindered because obese patients may be at risk for discrimination as well as higher risk of low self-esteem and depression.[2]

PATHOPHYSIOLOGY

The key factor in the development of overweight and obesity is the imbalance that occurs between energy intake and energy expenditure where intake exceeds expenditure. The extent of obesity is determined by the length of time this imbalance has been present. The hormone leptin, released from adipose tissue, is generally thought to play a major role in long-term weight homeostasis.[6] Leptin increases signaling to the hypothalamus as fat stores rise in attempt to reduce energy intake[7] (Figure 102–1). In the setting of obesity, leptin levels remain high, but eating behavior does not seem to be impaired, which is thought to be due in part to leptin resistance. Energy intake is affected by environmental influences and various gut hormones, whereas genetic composition and metabolism affect energy expenditure.[6] Many of the hormones produced in the gut that interact with the dorsal vagal complex and the hypothalamus represent target receptors or pathways for drugs that could possibly influence eating behavior. The mechanism behind most antiobesity medications is interacting with one of these signaling pathways to enhance anorexigenic signaling and thus decrease energy intake.

Energy Intake

Food intake is regulated by various receptor systems that comprise the gut-brain axis. Gut peptides travel via the vagus nerve or pass directly through the blood–brain barrier to affect the appetite control centers in the hypothalamus (see Figure 102–1).[7]. There are two groups of neurons in the arcuate nucleus (ARC) of the hypothalamus that send signals to higher brain centers and ultimately drive eating behavior. When neuropeptide Y or

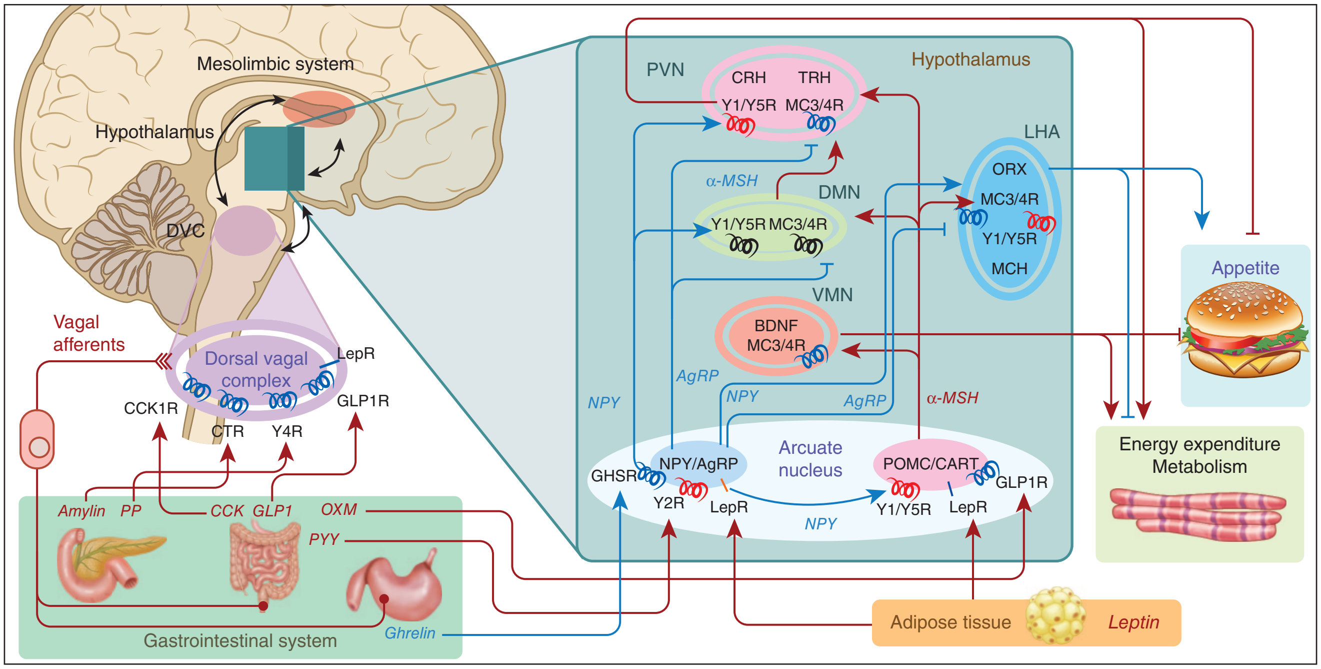

FIGURE 102–1. Central Energy of Appetite and Energy Homeostasis. (From Kim GW, Lin JE, Blomain ES, et al. Antiobesity pharmacotherapy: new drugs and emerging targets. Clin Pharmacol Ther. 2014;95(1):53–66.)

agouti-related peptide (NPY/AgRP) neurons in the ARC are stimulated by gut peptides such as ghrelin, eating ensues. When proopiomelanocortin or cocaine-amphetamine–regulated transcript (POMC/CART) neurons in the ARC are stimulated by various gut peptides or leptin, eating is halted. Stimulation of the following receptors increases and decreases food intake, respectively.

▶ *Increase Food Intake*

- Serotonin 1A subtype (5-HT$_{1A}$)
- Noradrenergic α$_2$
- Cannabinoid 1 (CB1)
- NPY/AgRP
- Melanin-concentrating hormone (MCH)
- Orexin

▶ *Decrease Food Intake*

- Serotonin 2C subtype (5-HT$_{2C}$)
- Noradrenergic α$_1$ or β$_2$
- Histamine subtypes 1 and 3
- Dopamine 1 and 2
- CART/POMC
- α-Melanocyte-stimulating hormone (α-MSH)

Targeting of this endogenous circuitry is a primary trait shared by many of the newer antiobesity medications on the market as well as those currently in development.

Energy Expenditure

A person's metabolic rate is the primary determinant of energy expenditure. The metabolic rate is enhanced immediately after food consumption and is directly related to the amount and type of food consumed.[8] After a period of weight loss, total energy expenditure is reduced as the body attempts to defend its previous "set point." Hence keeping weight off is just as challenging, if not more, than losing weight. Physical inactivity and/or endocrine-related disorders (eg, hypothyroidism and Cushing syndrome) may lower the metabolic rate, further contributing to the development of overweight and obesity.

CLINICAL PRESENTATION AND DIAGNOSIS

KEY CONCEPT Body mass index (BMI), waist circumference (WC), body fat percentage, comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients. Any interaction between a patient and a healthcare provider presents an opportunity to evaluate the patient's height and weight and calculate their BMI. These parameters should be measured no less than annually. The BMI is calculated using the measured weight in kilograms divided by the height in meters squared (kg/m^2) for all adult patients, regardless of gender and is used to classify overweight or obesity. The greater the BMI in overweight and obese individuals, the greater the risk of CVD, type 2 diabetes mellitus, and all-cause mortality.[9] The BMI distribution changes with age for children just as height and weight. Percentiles specific for age and gender are used to classify pediatric patients as overweight and obese as well as healthy and underweight.[10] BMI is classified according to Table 102–1.[2] Waist circumference should also be determined no less than annually for adult patients by placing a measuring tape at the top of the right iliac crest and proceeding around the abdomen, ensuring that the tape is tight but not constricting the skin. The value is measured after normal expiration. High-risk waist circumference is defined as greater than 40 in (102 cm) in men and greater than 35 in (89 cm) in women.[11] Measurement of waist circumference is not recommended for children and adolescents because reference values identifying risk are unavailable. After obtaining patient-appropriate parameters, further assess the adult patient for the presence of obesity-related comorbidities and cardiovascular risk factors. KEY CONCEPT The presence of obesity-related comorbidities (CVD, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors requires identification and aggressive management for overall effective treatment of the overweight or obese patient. A patient

Table 102–1

BMI Classification[2,10]

Adult	
Underweight	< 18.5 kg/m^2
Normal weight	18.5–24.9 kg/m^2
Overweight	25–29.9 kg/m^2
Obesity (Class 1)	30–34.9 kg/m^2
Obesity (Class 2)	35–39.9 kg/m^2
Extreme obesity (Class 3)	≥ 40 kg/m^2
Children (Only for Those > 2 Years of Age[a])	
Underweight	< 5th percentile
Healthy weight	5th–84th percentile
Overweight	85th–94th percentile
Obesity	≥ 95th percentile

[a] Weight for height values should be plotted and monitored over time for children less than 2 years of age.

is at very high absolute risk of a cardiovascular event if diagnosed with CVD, type 2 diabetes mellitus, or sleep apnea or if three or more of the following risk factors exist: cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, decreased high-density lipoprotein cholesterol, or impaired fasting glucose.[2] Aggressive disease management should be initiated and not limited to weight loss.

TREATMENT

Desired Outcome

KEY CONCEPT The treatment goals for overweight and obesity are to prevent additional weight gain, reduce and maintain a lower body weight, and control related risks. A 5% to 10% weight loss has been shown to improve obesity-related comorbidities such as hypertension, hyperlipidemia, and type 2 diabetes mellitus and thus serves as the initial goal for obesity treatment strategies.[9] A sustained 5% weight loss will likely reduce triglyceride and blood glucose values as well as risk for the development of type 2 diabetes mellitus.[9] Greater reductions in weight will reduce blood pressure and improve both low-density and high-density lipoprotein cholesterol. **KEY CONCEPT** Weight loss is indicated for patients with a BMI of 25 to 29.9 kg/m^2 with one or more indicators of increased CVD risk (eg, elevated WC, prediabetes or type 2 diabetes, hypertension, dyslipidemia, current cigarette smoker) or for any patient with a BMI of 30 kg/m^2 or greater. Weight loss should occur at a rate of 0.45 to 0.9 kg (1–2 lb) per week, meeting the initial weight loss goal within the first 6 months of therapy. If the patient achieves a 5% to 10% loss in weight, weight loss maintenance strategies should be considered. **KEY CONCEPT** Weight maintenance occurs after successful achievement of weight loss.

For children or adolescents, a BMI below the 85th percentile is warranted but is difficult to assess in frequent or short time periods. Serial weight measurements may better quantify energy balance. Goals are most likely accomplished through adaptation of lifelong healthy lifestyle habits. In doing so, weight loss or maintenance can be attained for some children. Others may need to incorporate changes that result in a negative energy balance or energy input less than energy output.[10]

General Approach to Treatment

Table 102–2

Drugs Contributing to Weight Gain[7,13]

- Anticonvulsants/mood stabilizers
  - Carbamazepine
  - Gabapentin
  - Pregabalin
  - Valproic acid
  - Lithium
- Antidepressants
  - Monoamine oxidase inhibitors (phenelzine)
  - Presynaptic α_2 antagonist (mirtazapine)
  - Selective serotonin reuptake inhibitors (citalopram, escitalopram, fluvoxamine)
  - Serotonin and norepinephrine reuptake inhibitors (duloxetine)
  - Tricyclics (amitriptyline, imipramine)
- Antidiabetics
  - Insulin
  - Meglitinides
  - Sulfonylureas (glipizide, glyburide)
  - Thiazolidinediones
- Antipsychotics
  - Atypical (clozapine, olanzapine, paliperidone, risperidone)
  - Conventional (haloperidol)
- Others
  - Antihistamines
  - Some nonselective β-blockers
  - Corticosteroids
  - Hormonal contraceptives (depot injections)

KEY CONCEPT Treatment of obesity includes comprehensive lifestyle intervention (caloric restricted diet, increased physical activity, and behavioral therapy to facilitate compliance with diet and exercise), pharmacologic treatment, surgical intervention, or a combination of modalities. Before initiating therapy, secondary causes of obesity (eg, hypothyroidism and Cushing syndrome) must be considered. Current treatment with medications that increase weight should be determined and, if present, alternative therapies should be suggested.[12,13] Table 102–2 provides a list of drugs commonly associated with weight gain. The American Association of Clinical Endocrinologists and The American College of Endocrinology have created a treatment algorithm for the treatment of obesity from patient presentation through follow-up (Figure 102–2).[14] Therapy implemented to minimize associated risk(s) may not enhance weight loss, but weight loss will positively address risk factors. Weight loss therapy should not be initiated in pregnant or lactating patients, decompensated psychiatric patients, or patients in whom reduced caloric intake can exacerbate an acute, serious illness.[2]

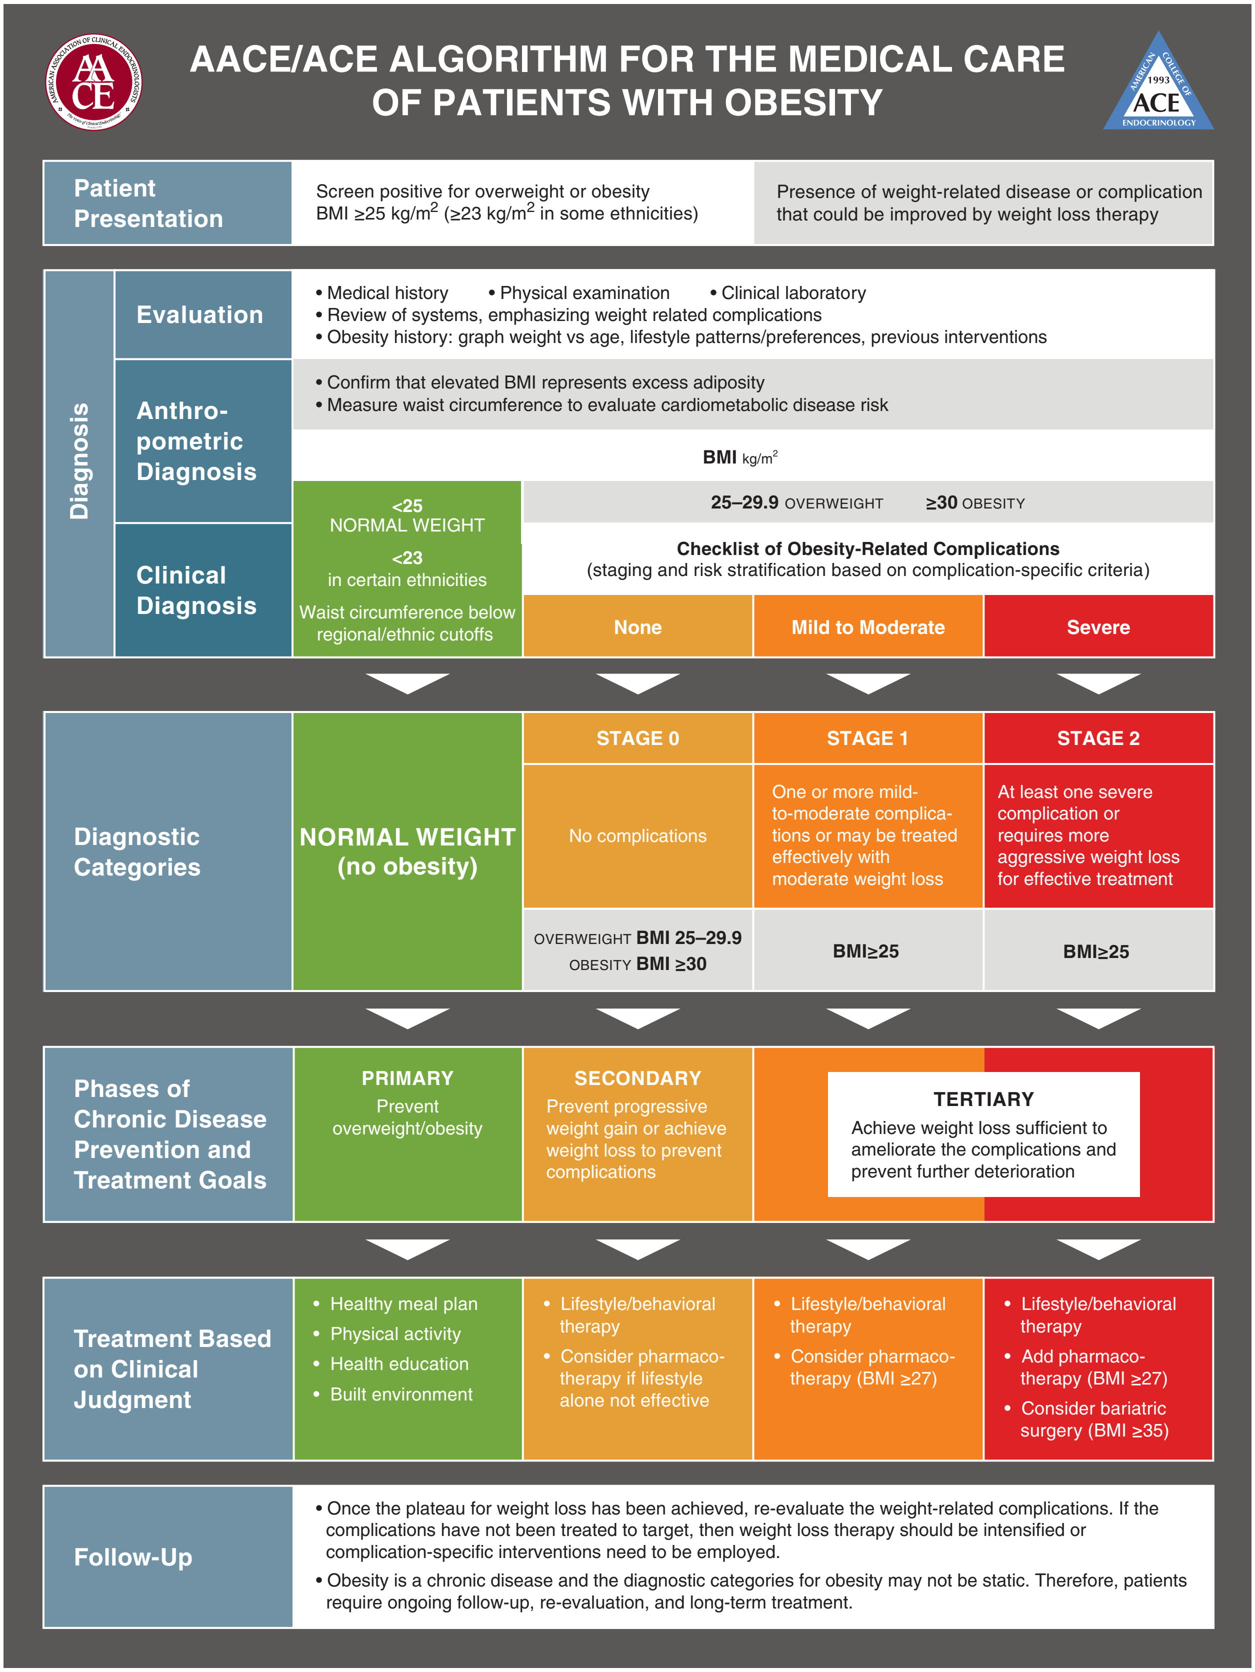
The treatment of pediatric obesity is a comprehensive strategy consisting of four main pillars: regulating quality and quantity of food intake, encouraging at least 60 minutes of physical activity daily while also limiting screen time to less than 1 to 2 hours per day, sleep regulation, and pharmacotherapy for those who qualify.[10]

Nonpharmacologic Therapy

Weight loss therapy requires the creation of an energy deficit. This may be achieved through daily caloric restriction and increased physical activity. Comprehensive lifestyle intervention and behavior modification is foundational to weight loss and should be recommended for all overweight or obese patients, even when adjunctive therapy with medications, devices, or bariatric surgery have been implemented. Table 102–3 indicates which treatment options may be appropriate according to BMI category.[11,15]

Reduced-Calorie Diet

Techniques to reduce dietary energy intake include adoption of a target energy intake less than that required for energy balance.



AACE/ACE ALGORITHM FOR THE MEDICAL CARE OF PATIENTS WITH OBESITY

Patient Presentation

Screen positive for overweight or obesity
BMI ≥25 kg/m² (≥23 kg/m² in some ethnicities)

Presence of weight-related disease or complication that could be improved by weight loss therapy

Diagnosis

Evaluation

- Medical history • Physical examination • Clinical laboratory
- Review of systems, emphasizing weight related complications
- Obesity history: graph weight vs age, lifestyle patterns/preferences, previous interventions

Anthropometric Diagnosis

- Confirm that elevated BMI represents excess adiposity
- Measure waist circumference to evaluate cardiometabolic disease risk

BMI kg/m²

<25 NORMAL WEIGHT
<23 in certain ethnicities
Waist circumference below regional/ethnic cutoffs

25–29.9 OVERWEIGHT **≥30** OBESITY

Clinical Diagnosis

Checklist of Obesity-Related Complications
(staging and risk stratification based on complication-specific criteria)

None	Mild to Moderate	Severe

Diagnostic Categories	**NORMAL WEIGHT (no obesity)**	**STAGE 0**	**STAGE 1**	**STAGE 2**
		No complications	One or more mild-to-moderate complications or may be treated effectively with moderate weight loss	At least one severe complication or requires more aggressive weight loss for effective treatment
		OVERWEIGHT **BMI 25–29.9** OBESITY **BMI ≥30**	**BMI≥25**	**BMI≥25**

Phases of Chronic Disease Prevention and Treatment Goals	**PRIMARY** Prevent overweight/obesity	**SECONDARY** Prevent progressive weight gain or achieve weight loss to prevent complications	**TERTIARY** Achieve weight loss sufficient to ameliorate the complications and prevent further deterioration	

Treatment Based on Clinical Judgment	Healthy meal plan Physical activity Health education Built environment	Lifestyle/behavioral therapy Consider pharmacotherapy if lifestyle alone not effective	Lifestyle/behavioral therapy Consider pharmacotherapy (BMI ≥27)	Lifestyle/behavioral therapy Add pharmacotherapy (BMI ≥27) Consider bariatric surgery (BMI ≥35)

Follow-Up

- Once the plateau for weight loss has been achieved, re-evaluate the weight-related complications. If the complications have not been treated to target, then weight loss therapy should be intensified or complication-specific interventions need to be employed.
- Obesity is a chronic disease and the diagnostic categories for obesity may not be static. Therefore, patients require ongoing follow-up, re-evaluation, and long-term treatment.

Abbreviation: BMI = body mass index

American Association of Clinical Endocrinologists and American College of Endocrinology Comprehensive Clinical Practice Guidelines for Medical Care of Patients with Obesity. Endocr Pract. 2016;22(suppl 3):1–203.

Table 102–3

Indications for Obesity Treatment by BMI Category[11,15]

	BMI Category				
Treatment	25–26.9	27–29.9	30–34.9	35–39.9	> 40
Bariatric surgery	No	No	Gastric banding with comorbidity	With comorbidity	Yes
Devices	No	No	Balloon	Aspire Assist Balloon vBloc[a] with comorbidity	Aspire Assist vBloc
Pharmacotherapy	No	With comorbidity	Yes	Yes	Yes
Lifestyle modification (diet, activity, behavior)	Yes	Yes	Yes	Yes	Yes

[a] vBloc, vagal nerve block therapy.

This can usually be accomplished by reducing the energy intake by 500 kcal/day (2100 kJ/day) or greater from current intake. Recommend total intake of 1200 to 1500 or 1500 to 1800 kcals/day (5000–6300 or 6300–7500 kJ/day) for women and men, respectively. The choice of calorie-restricted diet is based on patient preference and current health status. A variety of diets, including but not limited to, high-protein, low-carbohydrate, low-fat, Mediterranean and American Heart Association (AHA) Step-1 diet, can result in weight loss if reduction in dietary intake is achieved.[9] The AHA Step-1 diet restricts daily calories to a range of 1000 to 1200 kcal (4200–5000 kJ/day) for women weighing less than 75 kg (165 lb) and 1400 to 1600 kcal (5900–6700 kJ/day) for all others. This daily limit should be considered after assessing a patient's normal daily caloric intake and ensuring that the initial caloric restriction does not exceed 500 to 1000 kcal (2100–4200 kJ/day). For example, a male patient who consumes 3000 kcal (12,600 kJ/day) should not reduce his daily caloric intake to less than 2000 kcal (8400 kJ/day) when initially implementing a dietary program. Further reduction to the target of 1600 kcal (6700 kJ/day) can be attempted when the patient has reduced calories successfully, as initially recommended, for a period agreeable to the practitioner and the patient.[2] Diets too restrictive in calorie reduction are successful initially, but fail in the long term because compliance is difficult to sustain. Therefore, this less aggressive approach promotes gradual weight loss and weight maintenance. Consultation with a dietician is recommended when implementing a healthy meal plan tailored to the individual's nutritional needs.

Pediatric patients should be encouraged to consume three servings of protein daily, three servings of dairy daily, four to six servings of fruits and vegetables daily (majority from vegetables), avoid fast food, restrict dessert to special occasions only, and allowing the child to leave food on their plate if they feel full.[9]

▶ *Increased Physical Activity*

Although diet and exercise contribute to weight loss, combining a reduced-calorie diet with increased physical activity results in greater weight loss compared with either therapy alone.[11] In addition, physical activity can help prevent weight regain and reduce related cardiovascular risks.[9] Slow titration of both the amount and intensity of aerobic physical activity is recommended for most patients.[2] A program that incorporates walking daily is a viable option for most patients. Suggest starting with 10 minutes of physical activity 3 days/week and titrate up to 30 minutes most days as tolerated for optimal weight maintenance.[2,9] Pediatric patients should engage in at least 60 minutes of moderate-to-vigorous activity daily and limit nonacademic sedentary time.[10]

▶ *Behavioral*

Eliminating barriers through behavior modification is necessary to gain maximal benefit from both dietary modification and exercise. Successful behavioral therapy includes regular self-monitoring of food intake, physical activity, and weight.[9]

Targeted behaviors should be recommended to pediatric patients and their families because healthy habits help prevent excessive weight gain. These include, but are not limited to[10]:

- Limit the consumption of sugar-sweetened beverages.
- Limit the amount of screen time (television, computer, etc) to 2 hours or less per day.
- Limit the number meals eaten at restaurants, especially those serving fast food.
- Limit portion size when preparing and serving meals.

Pharmacologic Therapy

KEY CONCEPT Pharmacotherapy in addition to comprehensive lifestyle intervention can be considered for patients with a BMI of 30 kg/m^2 or greater, or a BMI of 27 kg/m^2 or greater with other obesity-related comorbidities. Obesity is a chronic disease that needs chronic treatment. There is no other chronic disease where therapy is withdrawn after a definitive time point. **KEY CONCEPT** Weight will likely be regained if lifestyle changes and/or therapeutic interventions are not continued indefinitely. Four drugs are approved for long-term use (at least 2 years) in promoting weight loss and preventing weight regain. If 4% to 5% weight loss is not achieved after 12 weeks of target dose therapy, the drug should be discontinued. Pharmacotherapy is not appropriate for women who are pregnant or lactating. Orlistat is the only agent approved for adolescent patients and is FDA approved for patients greater than 12 years of age.[16] All other pharmacotherapeutic agents are only approved for patients greater than 18 years of age. Table 102–4 summarizes currently available pharmacotherapeutic agents for weight management.[16-22] Much like current antiobesity medications, novel compounds in the pipeline focus on altering anorexigenic and orexigenic signaling and integration of various messages that drive eating behavior in the hypothalamus.[23]

▶ *Agents for Long-Term Use*

Orlistat Orlistat promotes and maintains weight loss by acting locally in the GI tract. It inhibits pancreatic and gastric lipases, as well as triglyceride hydrolysis. As a result, undigested triglycerides are not absorbed, causing a caloric deficit

Table 102–4

Pharmacotherapy for the Treatment of Obesity[16,22]

			Warnings	
Drug	Dose	Side Effects	Contraindications	Average Wholesale Price
Phentermine (Adipex P, Lomaira)	8–37.5mg daily (given in 1–3 divided doses)	Restlessness, tremor, palpitations or tachycardia, hypertension, cardiac valvulopathy, pulmonary hypertension	Tolerance develops after a few weeks Do not discontinue abruptly from max dose (seizure possible), avoid alcohol, hypokalemia if used with diuretics, avoid in hepatic dysfunction, take in morning to avoid insomnia History of drug abuse, cardiovascular disease, hyperthyroidism, glaucoma, administration of a monoamine oxidase inhibitor within 14 days	~$15–50
Phentermine/topiramate (Qsymia) Risk Evaluation and Mitigation Strategy (REMS) Program—pregnancy warning; cleft palate	3.75/23 mg daily × 14 days, 7.5/46 mg × 12 weeks Titrate up to 11.25/69 mg × 14 days then 15/92 mg daily if first 12 weeks successful Max dose 7.5/46 mg for CrCL < 50 mL/min (0.83 mL/s)	Constipation, paresthesias, xerostomia, blurred vision, impaired cognition, headache, kidney stones, increased upper respiratory tract infection, tachycardia, metabolic acidosis	Do not discontinue abruptly from max dose, avoid alcohol, hypokalemia if used with diuretics, avoid in hepatic dysfunction, take in morning to avoid insomnia Glaucoma, hyperthyroidism, administration of a monoamine oxidase inhibitor within 14 days	~$200–250
Bupropion/naltrexone (Contrave)	8/90 mg ER tab titrate up by 1 tab each week over 4 weeks to 32/360 mg given twice daily Limit to 1 tab twice a day for moderate-severe renal, and 1 tab daily for hepatic dysfunction	Nausea, vomiting, constipation, headache, dizziness, tachycardia, hypertension, insomnia, mood disturbances—report suicidal ideation immediately	Do not take with high-fat meals, **potential drug interactions:** other serotonergic drugs, antipsychotics, clopidogrel, antiretrovirals Seizure disorder, uncontrolled hypertension, history of eating disorder, **chronic opioid use**, administration of a monoamine oxidase inhibitor within 14 days	~$300
Liraglutide 3 mg (Saxenda) REMS: Thyroid C-cell tumors, acute pancreatitis	0.6 mg subcutaneously daily, increase by 0.6 mg each week up to 3 mg	Nausea, vomiting, diarrhea, constipation, headache, dizziness, dyspepsia (delayed gastric emptying), increased heart rate, acute pancreatitis, cholelithiasis	↓ Sulfonylurea or insulin dose by 50% Personal or family history of medullary thyroid cancer or endocrine neoplasia type 2	~$1500
Orlistat (Xenical—prescription) (Alli—OTC)	Xenical 120 mg three times daily with meals Alli 60 mg three times daily with meals	Abdominal pain, fecal urgency, leakage, incontinence, flatulence, steatorrhea	Take a multivitamin containing vitamins A, D, E, and K Cholestasis, malabsorption syndromes	~$500–550 ~$50–75

and weight loss. Two different orlistat products are available; prescription strength (Xenical 120 mg) and over-the-counter strength (Alli 60mg), and both are taken with each meal. Initiate orlistat with a well-balanced but reduced-caloric meal containing no more than 30% of calories from fat. Orlistat may be taken during or up to 1 hour after the meal. If a meal is missed or contains little fat, the dose of orlistat may be omitted. Doses above 360 mg/day provide no greater benefit and thus are not recommended.[16]

Prescription strength orlistat in combination with diet, exercise, and behavior modification resulted in a significant reduction in BMI and waist circumference in adolescents. In addition, orlistat-treated subjects exhibited minimal weight increase after 1 year.[16]

The safety and efficacy of orlistat have not been determined beyond 4 years of use. Orlistat's product label contains liver injury warning. Signs and symptoms of liver injury include itching, yellowing of the eyes or skin, dark urine, decreased appetite, and light-colored stools. Orlistat should be stopped if the patient complains of these signs and symptoms. In addition, liver function tests, should be assessed.[24]

Orlistat reduces the absorption of some fat-soluble vitamins. Daily intake of a multivitamin containing fat-soluble vitamins is recommended. Because the absorption of vitamin K may be reduced in patients receiving orlistat therapy, closer monitoring of coagulation status should occur in patients also taking warfarin.[16] Simultaneous administration of orlistat and some other medications may cause reduced absorption of the other medication and put the patient at increased risk of clinical adverse effects. Patients should take levothyroxine 4 hours before or after the orlistat dose and be monitored for changes in thyroid function. Administration of orlistat in conjunction with cyclosporine can result in decreased cyclosporine plasma levels. Cyclosporine should be taken 2 hours before or after the dose of orlistat, and cyclosporine levels should be monitored more frequently.[16]

Phentermine-Topiramate Phentermine-topiramate is an extended-release combination product. Phentermine decreases food intake by increasing norepinephrine and dopamine release in the central nervous system (CNS) which suppresses appetite. Topiramate is an antiepileptic drug whose exact mechanism of action is unknown. It is thought to increase satiety and suppress appetite through multiple pathways.[18]

Phentermine-topiramate use is associated with increased heart rate. Monitor resting heart rate frequently and have patients report the presence of palpitations. Topiramate can increase a patient's risk for suicidal thoughts and behaviors and alter mood. Patients should be monitored for worsening depression, thoughts of suicide, and unusual mood or behavior. Topiramate is contraindicated in patients with glaucoma or hyperthyroidism. Cognitive impairment is also associated with use of phentermine-topiramate; patients should proceed with caution when operating hazardous machinery including driving a car until the extent of impairment is known. An increase in serum creatinine and decrease in both potassium and bicarbonate have been reported.[18]

Because topiramate is a known teratogen, use of phentermine-topiramate during pregnancy is contraindicated. All women of childbearing potential should have a documented negative pregnancy result before this drug is initiated and monthly while on therapy.

Coadministration of phentermine-topiramate and monoamine oxidase inhibitor (MAOI) could result in a hypertensive crisis. Do not initiate phentermine-topiramate within 14 days of MAOI discontinuation. Phentermine-topiramate used in patients taking an oral contraceptive may cause irregular bleeding but not an increased risk of pregnancy. Advise patients to continue the oral contraceptives even if spotting occurs.

Initiate phentermine-topiramate at a dose of 3.75/23 mg daily and titrate to maximum dose as per Table 102–4. Discontinue drug or increase the dose of phentermine-topiramate if a 3% weight loss is not achieved in 12 weeks. If the decision is made to increase the dose, recommend 11.25/69 mg daily for 14 days then increase to 15/92 mg daily. Discontinue drug if a 5% weight loss is not achieved after 12 weeks at the highest drug dose. Due to the potential for drug abuse, phentermine-topiramate is a federally controlled substance (CIV). Gradually discontinue the 15/92 mg dose to prevent possible seizures from abrupt withdrawal.

Naltrexone-Bupropion Naltrexone-bupropion is an extended-release combination product. The exact mechanisms by which this opioid antagonist/antidepressant combination product decreases food intake and weight are not fully known but involve two separate areas of the brain (hypothalamus and mesolimbic dopamine circuit).[19]

Patients taking this product should be monitored for emergence or worsening of suicidal thoughts and behaviors and neuropsychiatric reactions. Bupropion inhibits CYP2D6 and can therefore increase the concentration of antidepressants, antipsychotics, and β-blockers. When taken with a CYP2B6 inhibitor (eg, clopidogrel), the concentration of bupropion increases. Reduce maximum daily dose by half in these patients. CYP2B6 inducers may reduce bupropion efficacy.[19]

Each extended-release tablet contains 8 mg of naltrexone and 90 mg of bupropion. Patients should be advised to not cut, crush, or chew tablets. Patients should also avoid taking naltrexone-bupropion with high-fat meals to minimize the risk of enhanced bupropion absorption and subsequent seizure occurrence. To further reduce the risk of seizures, the dose must be titrated slowly as suggested in Table 102–4.

Liraglutide 3 mg Liraglutide is an injectable analog of GLP-1 with a sequence that is 97% homologous with endogenously produced GLP-1.[17] When liraglutide stimulates GLP-1 receptors in the brain, signals of satiety are received and gastric emptying is delayed. A 50% dose reduction of sulfonylureas or any insulin is recommended with concomitant administration of liraglutide 3 mg in patients with type 2 diabetes. Acute pancreatitis occurs in 0.3% of patients taking liraglutide.[17]

Liraglutide is administered subcutaneously at a starting dose of 0.6 mg daily and increased to a target dose of 3 mg as suggested in Table 102–4. The dose increase may be delayed by 1 week if the patient is experiencing intolerable gastrointestinal adverse effects.

▶ *Agents for Short-Term Use*

Agents for short-term use are indicated as an adjunct to lifestyle modifications for no more than 12 weeks of use.[20,25,26] They are structurally related to amphetamine and work to suppress appetite. They can cause CNS stimulation and carry a potential for abuse. They should also not be used concurrently or within 14 days of an MAOI. These agents are cheaper than chronic obesity medications but often have more risky side effect profiles. These centrally acting sympathomimetic amines are generally not recommended for the treatment of chronic obesity.[14] Tolerance to the anorectic effect has been demonstrated, and these agents generally fail to produce long-term health benefits since weight regain tends to occur upon discontinuation of the drug.

Phentermine An average weight loss of 3.6 kg (7.9 lb) was demonstrated for patients treated with phentermine compared with placebo.[20]

Common adverse reactions seen with phentermine use include heart palpitations, tachycardia, elevated blood pressure, stimulation, restlessness, dizziness, insomnia, euphoria, dysphoria, tremor, headache, dry mouth, constipation, and diarrhea. Avoid phentermine in patients with CVD, hypertension, hyperthyroidism, and agitated states. Because phentermine is related to the amphetamines, the potential for abuse is high.[20] Alcohol is not recommended for patients prescribed phentermine.[20]

Phentermine is available as an immediate- and sustained-release product. In conjunction with a healthy lifestyle, 30 to 37.5 mg of phentermine is administered once daily, typically before breakfast or 1 to 2 hours after the morning meal. The dosage should be individualized; some patients may be managed adequately at 15 to 18.75 mg/day, but a dose of 18.75 mg twice daily may be used to minimize side effects, excluding insomnia. To lessen the risk of insomnia, dosing phentermine in the evening should be avoided.[20] A lower dose, 8-mg tablet, is given three times daily prior to meals.

Diethylpropion and Phendimetrazine These older sympathomimetic amines exhibit pharmacologic activity similar to amphetamines, resulting in CNS stimulation and appetite suppression.

Use of diethylpropion for a period longer than 12 weeks is associated with an increased risk for development of pulmonary hypertension.[25] When used as directed, reported common CNS adverse effects of these amphetamine derivatives included restlessness, dizziness, insomnia, euphoria, dysphoria, tremor, headache, anxiety, tachycardia, palpitations, dry mouth and constipation, mydriasis, and blurred vision.[25,26] In addition, diethylpropion can decrease the seizure threshold.[25] These agents are contraindicated in patients with pulmonary hypertension, advanced arteriosclerosis, severe hypertension, hyperthyroidism, agitated states, or glaucoma. Because these medications are related to the amphetamines, the potential for abuse is high.

Use of diethylpropion and phendimetrazine should be avoided in patients receiving or having an MAOI within the preceding 14 days to prevent hypertensive crisis. Combination with other anorectic agents should be avoided.[25,26]

Diethylpropion is available as both an immediate- and a controlled-release product. In conjunction with a reduced-calorie diet and/or exercise, dose diethylpropion (immediate release) 25 mg three times a day before meals or 75 mg (controlled release) once a day, usually midmorning.[25] Dose phendimetrazine extended release (105 mg) in the morning, 30 to 60 minutes before the morning meal or 35mg immediate release two to three times per day prior to meals. Phendimetrazine is a federally controlled substance (CIII).[25]

▸ Surgical Intervention

KEY CONCEPT Weight loss (bariatric) surgery is warranted when other treatment attempts have failed in severely obese patients (BMI $\geq 40\ \text{kg/m}^2$, or $\geq 35\ \text{kg/m}^2$ with obesity-related comorbidities).[2,11] Several surgical techniques exist; however, three are currently recognized as contemporary procedures: gastric bypass, which induces weight loss through both malabsorptive and restriction, sleeve gastrectomy, and laparoscopic adjustable gastric banding (LAGB), which achieve weight loss through restriction of food intake only.[27] Currently, the sleeve gastrectomy is the most commonly performed bariatric surgery procedure.[28]

Patient Encounter 1, Part 1

A 34-year-old woman presents to your weight loss clinic for an initial evaluation. She reports that her blood pressure was elevated upon screening while attending a community health fair. She followed up with her primary care provider who recommended adding another antihypertensive to her regimen, but she is wondering if weight loss may help her avoid being on more medications. Patient has gained 25 lb (11.3 kg) since her last check up 2 years ago. She is not currently following any specific diet. She admits to eating fast food 2 to 3 days per week. Patient is recently divorced (1 year ago) and does not enjoy cooking for one. This patient is currently part of a walking group where she walks 20 minutes per day roughly 2 days per week. The patient does not smoke and consumes one beer at least three nights per week. Her BMI is 39.3 kg/m^2, and her waist circumference is 39 in (99 cm).

What classification of overweight and obesity is appropriate for this patient?

Does this patient have a high-risk waist circumference?

Does she have other risk factors that may contribute to morbidity or mortality?

What are the treatment goals for the patient?

What additional information do you need to know before creating a treatment plan for this patient?

Patient Encounter 1, Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Type 2 diabetes mellitus, persistent lower back pain, heartburn, depression, insomnia, kidney stones × 2

FH: Father alive and 68 years of age. Mother also alive (age 65) with history of obesity.

SH: (–) Tobacco, (+) alcohol

Meds: Hydrocodone/acetaminophen 5/325 one tablet orally at bedtime, pantoprazole 40 mg orally once per day, citalopram 20 mg orally once per day, metformin 1000 mg orally twice per day, sitagliptin 50 mg orally once per day, Bydureon 2 mg subcutaneously once weekly, lisinopril 20 mg orally daily, and zolpidem 5 mg orally at bedtime for sleep

ROS: (+) Heartburn; (–) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

PE:

VS: BP 147/88 mm Hg, P 92 beats/min, RR 16 breaths/min, T 98.6°F (37°C)

Weight: 193 lb (87.5 kg); ht: 64 in (163 cm)

Cardiovascular: Normal S_1S_2; no murmurs, rubs, gallops

Abdominal: Obese, soft, nontender, nondistended; (+) bowel sounds

Extremities: (–) Edema

Labs: Glucose (118 mg/dL [6.5 mmol/L]) and HbA_{1C} (6% [0.06 or 42 mmol/mol Hgb]).

ECG: Normal. No evidence of past ischemia

Given this additional information, do you recommend weight loss? If so, how much weight should the patient lose and how fast?

What nonpharmacologic and pharmacologic treatments are available for the patient?

Would you recommend any changes to her current medication regimen to assist with her weight loss?

If you elected to start her on a pharmacotherapeutic agent for weight loss, what would you need to monitor and when would you recommend the patient come back for follow-up?

Surgical options for obesity provide the most effective and sustainable weight loss results and may produce a loss of two-thirds of excess body weight after 2 years.[2] Additionally, very favorable outcomes for obesity-related comorbid conditions are observed.[29] Risk versus benefit must be considered as complications are inherent to any surgical procedure, but the overall likelihood of major complications is less than 4%. Possible short-term complications include pulmonary embolism, wound infection, and anastomotic leak. The overall risk of mortality from bariatric surgery is about 0.1%. Several studies have compared mortality in obese patients who have underwent bariatric surgery to those who have not and consistently found reduced mortality rates in the surgical population.[29]

Bariatric surgery is an alternative offered to adolescents because it results in substantial weight loss and medical health improvement.[30] Adolescent patients should be managed by a multidisciplinary team that can provide psychosocial, nutritional, and exercise support.[31] Both adult and pediatric surgical patients must understand and commit to a substantial change in eating and activity patterns to maintain long-term weight reduction.

Postoperatively, healthcare providers should also make considerations for medication management as these procedures may alter drug and nutrient absorption.[32]

- If safe to do so for individual medications, crush tablets, open capsules, or use liquid formulations to replace sizeable pills until appropriate to restart solid foods (likely variable per program.
- Avoid nonsteroidal anti-inflammatory drugs (NSAIDs), diuretics, oral bisphosphonates, and potentially extended- or delayed-release products for malabsorptive procedures.
- Certain micronutrient supplements may be indicated depending on procedure type (eg, fat-soluble vitamins, iron, vitamin B_{12}).
- Nonoral routes of administration may be considered if available.

Devices

Weight loss devices require a minimally invasive outpatient procedure since most of them are endoscopically placed. There are currently three types of devices approved for use in adult patients by the FDA: vagal nerve blocking stimulators (vBloc), gastric balloons, and gastric emptying systems. Indications for use are dependent on BMI category and/or presence of obesity-related comorbidities (see Table 102–3), and some are only approved for short-term therapy (6 months).[11,15] Devices are associated with an overall equal to or greater weight loss profile compared to pharmacotherapy but are not quite as effective as bariatric surgery.[15] Devices are associated with some similar adverse effects but an overall lesser serious complication rate compared to bariatric surgery.[15]

Patient Encounter 2, Part 1

A 51-year-old White man presents to your CVD Risk Reduction Clinic. The patient currently denies chest pain, shortness of breath, dizziness, or light-headedness. He just mentions being fatigued a lot. He is supposed to wear a CPAP machine at night but admits he frequently takes it off in the middle of the night. You review his labs today and find his LDL to be elevated. As a computer programmer who works from home, he finds himself sitting more than engaging in physical activity. He frequently eats fast food for lunch. Evenings are spent in watching TV. He claims his knee arthritis limits his exercise ability. He is a half pack per day smoker. The patient's BMI is 34 kg/m^2, and waist circumference is 40 in (102 cm). He presents to the clinic today seeking recommendation for weight loss and says he is willing to make changes to better his health.

What classification of overweight and obesity is appropriate for this patient?

Does this patient have a high-risk waist circumference?

Does he have other risk factors that may contribute to morbidity or mortality?

What are the treatment goals for the patient?

What additional information do you need to know before creating a treatment plan for this patient?

Patient Encounter 2, Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Occasional headache, hypertension, osteoarthritis of the left knee, irritable bowel syndrome (diarrhea predominant)

FH: Father alive and 78 years of age. Mother also alive and 77 years of age.

SH: Drinks alcohol occasionally (socially) but denies any alcohol-related problems

Meds: Lisinopril/hydrochlorothiazide 10/25 mg orally daily, aspirin 81 mg orally daily, metformin 1000 mg orally twice a day, atorvastatin 10 mg orally daily, amitriptyline 25 mg orally at bedtime, Excedrin migraine two tabs orally as needed headache, acetaminophen 650 mg orally four times a day as needed for knee pain

ROS: (–) Heartburn, regurgitation; (–) chest pain, nausea, vomiting, diarrhea, no change in appetite, no shortness of breath, or cough

VS: BP 129/79 mm Hg, P 72 beats/min, RR 15 breaths/min, T 98.7°F (37.1°C)

Weight: 262 lb (119 kg)

Height: 73 in (185 cm)

Waist circumference: 40 in (102 cm)

PE:

General: Well developed, in no acute distress

HEENT: Conjunctiva clear

CV: Regular rhythm, no S_3 or S_4 noted

Lungs: Clear to auscultation (CTA) bilaterally

Abd: Obese, soft, nontender, nondistended; (+) bowel sounds

Neuro: Normal gait, normal speech

Ext: (–) Edema

Labs:

Na: 142 mEq/L (mmol/L); **K:** 4.6 mEq/L (mmol/L); **Cl:** 107 mEq/L (mmol/L); **CO2:** 23 mEq/L (mmol/L); **BUN:** 18 mg/dL (6.4 mmol/L); **Creatinine:** 0.9 mg/dL (80 μmol/L); **glucose:** 110 mg/dL (6.1 mmol/L); **HbA1C:** 6.9% (0.069; 52 mmol/mol Hgb)

TC: 213 mg/dL (5.51 mmol/L); **LDL:** 110 mg/dL (2.84 mmol/L); **HDL:** 30 mg/dL (0.78 mmol/L); **TG:** 152 mg/dL (1.72 mmol/L)

AST: 24 U/L (0.40 μkat/L); **ALT:** 30 U/L (0.50 μkat/L)

What would be the optimal treatment strategy for this patient?

Vagal Nerve Block Stimulator The vBloc system contains a pacemaker-like device that is implanted under the skin and connects to electrodes that are attached to the vagus nerve. It blocks hunger signals sent from the stomach to the brain along the vagus nerve. The vBloc system is not appropriate for patients with hepatic cirrhosis or those who have another electronic medical device already implanted.[33]

Gastric Balloons Three medical-grade silicone gastric balloons are currently available for endoscopic placement and inflation in the stomach: Reshape, Orbera, and Obalon. The balloon reduces the amount of food that a patient can consume by taking up significant space in the stomach. After 6 months, balloons must be removed. Most common adverse events are nausea/vomiting, abdominal pain, and gastric ulcers.

Reduced calorie absorption system The Aspire Assist device works by removing roughly one-third of the food consumed from the stomach before it reaches the intestinal tract, effectively reducing the calories absorbed from food.[15] A tube is placed into the stomach and connects to a small button on the outside of the abdomen. Roughly 20 to 30 minutes after a meal, the patient connects the tube to a handheld device that then pumps food out of the stomach and into the toilet. The most common adverse effects are abdominal discomfort and button site irritation.

OUTCOME EVALUATION

Successful management of overweight and obesity is determined by the ability the treatment plan has to (a) prevent weight gain, (b) reduce and maintain a lower body weight, and (c) decrease the risk of obesity-related comorbidities. Obesity management may encompass more than weight loss or maintenance in the presence of other conditions such as hypertension, type 2 diabetes mellitus, hyperlipidemia, CVD, sleep apnea, hypothyroidism, osteoarthritis, gallbladder disease, gout, or cancer. Measure blood pressure and heart rate before implementation of any therapy and assess basic metabolic panel, liver function tests, complete blood count, fasting lipid profile, thyroid function tests, and other laboratory studies at baseline and as clinically indicated. Additionally, obtain an electrocardiogram if recent results are unknown.

When considering various approaches to behavioral therapy for weight loss, in-person, high-intensity (defined as a minimum of 14 sessions within 6 months) behavioral therapy is the most effective. During each session, assess compliance with comprehensive lifestyle intervention, as well as measure weight, blood pressure, and heart rate. Measure waist circumference intermittently. Identify presence of adverse drug reactions or drug interactions if weight loss medications have been initiated.

When the patient has achieved the recommended weight loss, he or she then enters the weight maintenance phase, which includes continued contact for education (no less than monthly), guidance, and risk factor assessment. Self-weighing, at least weekly, is associated with better weight maintenance over time. Counsel patient to address small weight gains before they become larger.[9]

If weight loss is not attained, further assess why the goals of therapy are unmet. Direct the interaction toward determining the motivation to lose weight, balance between caloric intake and physical activity, adherence to behavioral therapy, and determination of psychological stressors present. Refer patient to a nutrition professional or for evaluation for bariatric surgery if eligibility criteria are met. If adjunctive pharmacotherapy has not been initiated, consider antiobesity drugs approved for long-term use.

Patient Care Process

Collect Information:

- Measure weight and height.
- Calculate and classify BMI.
- Medical history, current medications, and laboratory data for secondary causes of weight gain.
- Current lifestyle and history of weight gain/loss.

Assess the Information:

- CVD risks and obesity-related comorbidities.
- Need to lose weight (candidates include obese patients or overweight patients with at least one indicator of increased CVD risk).
- Readiness to make lifestyle changes.
- Weight loss goals.

Develop a Care Plan:

- Comprehensive lifestyle intervention strategies (restricted caloric-diet, increased physical activity, and behavioral therapy).
- Determine eligibility for obesity pharmacotherapy and, if so, verify if insurance coverage exists for the patient or if they qualify for any manufacturer offered discount cards.
- If patient is already receiving an antiobesity medication, assess efficacy, safety, adherence, and potential drug interactions.

Implement the Care Plan:

- Manage CVD risk factors such as hypertension, dyslipidemia, etc.
- Encourage self-weighing, at least weekly, for better weight loss and maintenance over time.
- Keep weight monitoring log to take to future follow-up visits.

Follow-up: Monitor and Evaluate:

- In 2 weeks, patient may self-assess weight, blood pressure, heart rate, and adherence with comprehensive lifestyle intervention. Assess weight monitoring log.
- Every 4 weeks, reassess patient in person.
- Once weight loss is achieved, continue contact with patient monthly, if possible. Address small weight gains and continued adherence with comprehensive lifestyle intervention.

Abbreviations Introduced in This Chapter

AST	Aspartate transaminase
ALT	Alanine aminotransferase
BMI	Body mass index
CB1	Cannabinoid receptor
CNS	Central nervous system
CVD	Cardiovascular disease
FDA	Food and Drug Administration
5-HT$_{1A}$	Serotonin 1A subtype
5-HT$_{2C}$	Serotonin 2C subtype
GI	Gastrointestinal
MAOI	Monoamine oxidase inhibitor

Appendix A: Prescription Writing Principles

Kim Hawkins, Jill Isaacs, Emily Knezevich, and Jon Knezevich

Approximately 4 billion prescriptions are written and dispensed in the United States annually, with 80% of those prescribed digitally.[1] This reflects a need for prescribers and dispensers to fully understand prescriptive privileges and rational prescribing.[2] The following outlines principles of pharmacotherapy, including general considerations of prescribing, rational prescribing of medications, types of prescription orders, safe prescribing practices including the importance of handwriting and electronic prescribing, adverse event reporting, and medication education.

It is essential that the prescriber and dispenser familiarize themselves with professional guidelines, state laws, and federal laws. In addition, they must understand the components of rational prescribing. Table A–1 provides key elements a prescriber should understand as well as useful resources.

TYPES OF PRESCRIPTION ORDERS

Prescription orders can be provided in a variety of ways by authorized prescribers. Outpatient prescriptions may be generated in a format that is handed to the patient directly. For example, prescriptions can be handwritten, typed, or computer generated and printed. A verbal format could also be used, making the prescription available for retrieval at the pharmacy without a physical prescription in hand. This can be accomplished by verbally authorizing the prescription with a phone call to the pharmacy staff or leaving a message on the pharmacy voicemail, which must be immediately reduced to written format when received. A fax could also be used to generate the prescription. Most commonly, the prescription can be provided electronically through e-prescribing. This allows the prescription to be communicated directly from the provider's electronic medical record to the pharmacy's database for dispensing. All outpatient prescriptions are subject to federal regulations and contain the same basic components. Laws and regulations for outpatient prescription requirements can vary from state to state, so prescribers should be knowledgeable of all applicable laws. The basic components of a prescription are listed below as well as numbered in Figure A–1.[3]

- Prescriber information: name, address, and phone number
- Prescriber's signature and prescriptive authority number or Drug Enforcement Administration (DEA) number (if applicable)
- Patient information: full name and address, and weight and age if appropriate
- Date the prescription was written
- Superscription (Rx symbol), meaning "you take" or "recipe"; not required but traditionally seen
- Inscription: medication being prescribed (name of medication, strength, and dose)
- Signa, sig, or signature: directions to the patient (eg, take one tablet daily)
- Subscription: dispensing instructions to the pharmacist (number, quantity, or volume to dispense)
- Number of refills allowed
- Generic substitution requirement: "DAW (dispense as written)" or "no substitution" if brand name medication only is desired. The specific wording requirement may vary by state.

Further regulations are in place for prescriptions written for controlled substances.[4] In addition to the above elements, prescriptions for controlled substances must also include the patient's full name and address as well as the full name, address, and DEA number of the prescriber. Stricter regulations exist for schedule II–controlled substances compared with schedules III and IV. Schedule II prescriptions must be written and can only be provided orally in an emergency situation. When provided orally, this must be documented and matched with a written authorization within 7 days. However, with advancements in security capabilities of electronic medical records (EMR), the DEA amended this to provide an option to issue schedule II prescriptions electronically. Federal and state rules must be followed. In cases where federal and state laws conflict, the stricter law must be adhered to.[5] Refills are prohibited with schedule II prescriptions, with partial refills allowed under specific circumstances; however, this practice must adhere to both federal and state laws.[6] Schedule III and IV prescriptions may be refilled up to five times within 6 months of when the prescription was issued. Due to the opioid epidemic, many states have enacted stricter prescribing laws to reduce prescription fraud and abuse. Prescribers need to be aware of individual state requirements.

Orders listed in the medical record for hospitalized patients are not considered prescriptions and are not subject to the same requirements. However, in most hospitals, almost all orders are done electronically, with written orders being the exception. Typically, medical record orders include:

- Patient identifiers including name, account number.
- Prescriber name.
- Medication name, dose, route, and frequency of administration.
- Date and time of order.
- Prescriber signature (electronic).
- If the order was given verbally, the person reducing the order to writing must sign the order and the ordering provider countersign.

Table A–1

Pharmacotherapy Principles

Pharmacotherapy Principle	Description	Online Resources
Prescriptive privileges	Dictated by federal and state law	
	Scope of practice and formularies vary by profession. Physicians, nurse practitioners, physician assistants, and dentists all have varying scopes of practice, which may include formularies or supervising prescribers. Each provider must become familiar with his or her profession's scope of practice.	
	Pharmacology courses in program of study and Continuing Education required	
	Prescribing legend drugs requires board examination and National Provider Identifier (NPI)	https://nppes.cms.hhs.gov/NPPES/Welcome.do
	Prescribing controlled substances requires DEA registration number	http://www.justice.gov/dea/
Rational prescribing	Ensure necessity of medication	
	Obtain pertinent history	
	• Health history: comorbidities or contraindications (ie, pregnancy, hepatic failure, or renal failure)	
	• Medication history: prior and current prescription, OTC, or herbal use; drug allergies or sensitivities; compliance issues	
	• Family and social history	
	Select correct medication	http://www.jointcommission.org/
	• It is important to know the following components of each medication when prescribing or dispensing:	
	• Pharmacokinetics	
	• Pharmacodynamics	
	• Drug interactions	
	• Drug–disease interactions	
	• Interdisciplinary collaboration when necessary	

DEA, Drug Enforcement Administration; OTC, over the counter.

Electronic prescribing has become common practice because of government incentives aimed at moving health records to electronic databases with the goal of improving healthcare processes.[7] Principles discussed previously in regard to requirements of a prescription hold true for electronic orders; however, additional considerations must be taken to ensure safe prescribing habits. A brief list of potential barriers and benefits is summarized in Table A–2.

Electronic prescribing is no longer a projection of the future but instead has become the norm. With appropriate use of this technology, patients are provided with safer and more efficient care.

Omission of any of the above-discussed elements on a prescription order can be considered erroneous and poses a danger to patient care. Responsibility lies with the prescriber as well as the pharmacist dispensing the medication to ensure prescriptions are accurate and appropriate for each patient. State laws for electronic prescribing must also be considered.

SAFE PRESCRIBING PRACTICES

Safe prescribing should be a priority for all healthcare providers. To avoid inappropriate use of medications, prescribers should take careful consideration in writing clear and descriptive prescriptions. This ensures appropriate communication among the interdisciplinary healthcare team.

DEA AA1234563

FIGURE A–1. Example of a prescription.

Table A–2

Electronic Prescribing[8-9]

Benefits	Barriers
Reduce medication errors	Cost of software programs
Reduce adverse drug events	Lack of financial benefit seen immediately
Improves efficiency	Lack of software standardization
Improved recognition of drug–drug and drug–disease interactions	Indirect costs: training personnel, reduced patient visits during training period
Improved recognition of medication allergy cross-sensitivity	Clinician resistance: worry of worsening relationship with patient, negative impact on workflow, and fears of restrictions on prescribing habits
Enhanced prescriber knowledge of patient adherence	
Enhanced prescriber knowledge of insurance coverage for medications	

Table A–3

Sound-Alike/Look-alike Medications[10]

Medication Name	Misinterpreted Medication Name
aceto**HEXAMIDE**	aceta**ZOLAMIDE**
chlordiaze**POXIDE**	chlorpro**MAZINE**
CISplatin	**CARBO**platin
e**PHED**rine	**EPINEPH**rine
hydr**ALAZINE**	hydr**OXY**zine
LORazepam	**ALPRAZ**olam
NIFEdipine	ni**CAR**dipine
RABEprazole	**ARIP**iprazole
risperi**DONE**	r**OPINIR**ole
sulf**ADIAZINE**	sulfa**SALA**zine
val**ACY**clovir	val**GAN**ciclovir
Zantac	Xanax

A thorough understanding of the medication prescribed, including its expected risks and benefits, should be realized by the prescriber ensuring appropriate drug selection. Providers must also be able to recognize and avoid common errors related to prescription writing. These errors include sound-alike/look-alike medications and inappropriate use of shorthand language and abbreviations. The Joint Commission, as well as the Institute for Safe Medication Practices (ISMP), has collected common examples of these errors seen during the ordering process. Common examples are described in Tables A–3 and A–4.

Table A–4

Error-Prone Abbreviations[11]

Abbreviation	Anticipated Meaning	Misinterpretation	Correction
µg	Microgram	Mistaken as “mg”	Use “mcg”
IJ	Injection	Mistaken as “IV” or “intrajugular”	Use “injection”
q.d. or QD	Every day	Mistaken as qid, especially if the period after the “q” or the tail of the “q” is misunderstood as an “i”	Use “daily”
U	Units	May appear as a µ or 0	Use “units”
IU	International Units	IV (intravenous)	Use “units”
bid, tid, qid	Twice daily, three times daily, four times daily	Depending on handwriting, may be misinterpreted a number of ways.	Write out the words “twice daily,” etc.
biw, tiw, qiw	Twice weekly, three times weekly, four times weekly	Two times per day, three times per day, four times per day	Write out the words “twice weekly,” etc.
Dose Designation	**Anticipated Meaning**	**Misinterpretation**	**Correction**
Trailing zero after decimal point (eg, 4.0 mg)	4 mg	Mistaken as 40 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in whole numbers
No leading zero before a decimal point (eg, .8 mg)	0.8 mg	Mistaken as 8 mg if the decimal point is NOT seen	Use zero before a decimal point when the dose is less than a whole unit
Large doses without properly placed commas (eg, 100000 units;1000000 units)	100,000 units 1,000,000 units	100000 has been mistaken as 10,000 or 1,000,000; 1000000 has been mistaken as 100,000	Use commas for dosing units at or above 1,000 or use words such as 100 “thousand” or 1 “million” to improve readability
Drug Name Abbreviation	**Anticipated Meaning**	**Misinterpretation**	**Correction**
AZT	Zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use complete drug name
MS, MSO4	Morphine sulfate	Mistaken as magnesium sulfate	Use complete drug name
PCA	Procainamide	Mistaken as patient-controlled analgesia	Use complete drug name
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name
Stemmed Drug Names	**Anticipated Meaning**	**Misinterpretation**	**Correction**
“Nitro” drip	Nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
“IV Vanc”	Intravenous vancomycin	Mistaken as Invanz	Use complete drug name
Symbol	**Anticipated Meaning**	**Misinterpretation**	**Correction**
x3d	For three days	Mistaken as 3 doses	Use “for three days”
&	And	Mistaken as “2”	Use “and”
°	Hour	Mistaken as a zero (eg, q2° seen as q 20)	Use “hr,” “h,” or “hour”

Available from: http://ismp.org/tools/errorproneabbreviations.pdf

Other commonly used medical abbreviations used in prescription writing can be found in Appendix C: Common Medical Abbreviations.

Adverse Event Reporting

Adverse events may occur related to inappropriate prescribing, dispensing, or administering medications. Inappropriate prescribing may be avoided by ensuring care is taken to determine all pertinent patient-related issues are discussed during the encounter. Additionally, appropriate interdisciplinary care where multiple healthcare providers are evaluating and treating the patient's problem may help avoid adverse events from occurring. Inappropriate dispensing and administration may be avoided through use of clear order entry that undergoes multiple checks by a variety of providers before a prescription reaches the patient. Movement to electronic prescribing has helped eliminate many issues with misinterpreting handwritten orders; however, should they still be encountered, providers should take care to write prescriptions very legibly. If any questions remain upon receipt of a questionable order, verification should occur with the writing provided by the dispensing pharmacist. If adverse events related to medication use are determined, the healthcare provider who discovers the event is responsible for reporting it. The Food and Drug Administration's reporting system for such adverse events is MedWatch.[12] This online database archives medication-related adverse events, and providers are able to report errors seen in clinical practice.

Medication Education

After a prescription has been written, counseling patients on newly prescribed therapies is an essential responsibility of the prescriber and pharmacist. The patient should be made aware of the rationale for drug use, the dose, route, and frequency at which they should administer the medication and expectations of the prescribed drug. Expectations should include risks and benefits to avoid patient confusion about side effects or efficacy measures. Thorough discussion with the patient about the selected medication therapy may identify contraindications previously unknown or a patient history of failure or success with the selected agent in the past. Some high-risk medications require special programs that must be completed by prescribers and/or patients as well.

CONCLUSION

Multiple principles must be exercised for appropriate drug delivery from the bedside to the patient. As a healthcare provider, understanding these processes helps to ensure safe medication prescribing.

Appendix B: Conversion Factors and Anthropometrics*

CONVERSION FACTORS

SI Units

SI (*le Systéme International d'Unités*) units are used in many countries to express clinical laboratory and serum drug concentration data.* Instead of using units of mass (eg, micrograms), the SI system uses moles (mol) to represent the amount of a substance. A molar solution contains 1 mole (the molecular weight of the substance in grams) of the solute in 1 L of solution. The following formula is used to convert units of mass to moles (mcg/mL to µmol/L or, by substitution of terms, mg/mL to mmol/L or ng/mL to nmol/L).

▶ *Micromoles per Liter*

$$\text{Micromoles per liter } (\mu\text{mol/L}) = \frac{\text{drug concentration (mcg/mL)} \times 1000}{\text{molecular weight of drug (g/mol)}}$$

▶ *Milliequivalents*

An equivalent weight of a substance is the weight that will combine with or replace 1 g of hydrogen; a milliequivalent is 1/1000 of an equivalent weight.

Milliequivalents per Liter

$$\text{Milliequivalents per liter (mEq/L)} = \frac{\text{weight of salt (g)} \times \text{valence of ion} \times 1000}{\text{molecular weight of salt}}$$

$$\text{Weight of salt (g)} = \frac{\text{mEq/L} \times \text{molecular weight of salt}}{\text{valence of ion} \times 1000}$$

Approximate Milliequivalents: Weight Conversions for Selected Ions

Salt	mEq/g Salt	mg Salt/ mEq
Calcium carbonate ($CaCO_3$)	20.0	50.0
Calcium chloride ($CaCl_2 \cdot 2H_2O$)	13.6	73.5
Calcium gluceptate ($Ca[C_7H_{13}O_8]_2$)	4.1	245.2
Calcium gluconate ($Ca[C_6H_{11}O_7]_2 \cdot H_2O$)	4.5	224.1
Calcium lactate ($Ca[C_3H_5O_3]_2 \cdot 5H_2O$)	6.5	154.1
Magnesium gluconate ($Mg[C_6H_{11}O_7]_2 \cdot H_2O$)	4.6	216.3
Magnesium oxide (MgO)	49.6	20.2
Magnesium sulfate ($MgSO_4$)	16.6	60.2
Magnesium sulfate ($MgSO_4 \cdot 7H_2O$)	8.1	123.2
Potassium acetate ($K[C_2H_3O_2]$)	10.2	98.1
Potassium chloride (KCl)	13.4	74.6
Potassium citrate ($K_3[C_6H_5O_7] \cdot H_2O$)	9.2	108.1
Potassium iodide (KI)	6.0	166.0
Sodium acetate ($Na[C_2H_3O_2]$)	12.2	82.0
Sodium acetate ($Na[C_2H_3O_2] \cdot 3H_2O$)	7.3	136.1
Sodium bicarbonate ($NaHCO_3$)	11.9	84.0
Sodium chloride ($NaCl$)	17.1	58.4
Sodium citrate ($Na_3[C_6H_5O_7] \cdot 2H_2O$)	10.2	98.0
Sodium iodide (NaI)	6.7	149.9
Sodium lactate ($Na[C_3H_5O_3]$)	8.9	112.1
Zinc sulfate ($ZnSO_4 \cdot 7H_2O$)	7.0	143.8

Valences and Atomic/Molecular Weights of Selected Ions

Substance	Electrolyte	Valence	Atomic/Molecular Weight
Calcium	Ca^{2+}	2	40.1
Chloride	Cl^-	1	35.5
Magnesium	Mg^{2+}	2	24.3
Phosphate	HPO_4^{2-} (80%)	1.8	96.0[a]
(pH = 7.4)	$H_2PO_4^-$ (20%)		97.0
Potassium	K^+	1	39.1
Sodium	Na^+	1	23.0
Sulfate	SO_4^-	2	96.0[a]

[a] The atomic/molecular weight of phosphorus is only 31; that of sulfur is only 32.1.

---

Anion Gap

The anion gap is the concentration of plasma anions not routinely measured by laboratory screening. It is useful in the evaluation of acid–base disorders. The anion gap is greater with increased plasma concentrations of endogenous species (eg, phosphate, sulfate, lactate, and ketoacids) or exogenous species (eg, salicylate, penicillin, ethylene glycol, ethanol, and methanol). The formulas for calculating the anion gap are as follows:

$$\text{Anion gap} = (\text{Na}^+ + \text{K}^+) - (\text{Cl}^- + \text{HCO}_3^-)$$

or

$$\text{Anion gap} = \text{Na}^+ - (\text{Cl}^- + \text{HCO}_3^-)$$

where the expected normal value for the first equation is 11 to 20 mmol/L and for the second equation is 7 to 16 mmol/L. Note that there is a variation in the upper and lower limits of the normal range.

Temperature

Fahrenheit to Celsius: (°F – 32) × 5/9 = °C

Celsius to Fahrenheit: (°C × 9/5) + 32 = °F

Celsius to Kelvin: °C + 273 = °K

Weights and Measures

▶ *Metric Weight Equivalents*

1 kilogram (kg) = 1000 grams

1 gram (g) = 1000 milligrams

1 milligram (mg) = 0.001 gram

1 microgram (mcg, µg) = 0.001 milligram

1 nanogram (ng) = 0.001 microgram

1 picogram (pg) = 0.001 nanogram

1 femtogram (fg) = 0.001 picogram

▶ *Metric Volume Equivalents*

1 liter (L) = 1000 milliliters

1 deciliter (dL) = 100 milliliters

1 milliliter (mL) = 0.001 liter

1 microliter (µL) = 0.001 milliliter

1 nanoliter (nL) = 0.001 microliter

1 picoliter (pL) = 0.001 nanoliter

1 femtoliter (fL) = 0.001 picoliter

▶ *Apothecary Weight Equivalents*

1 scruple (э) = 20 grains (gr)

60 grains (gr) = 1 dram (ʒ)

8 drams (ʒ) = 1 ounce (℥)

1 ounce (℥) = 480 grains (gr)

12 ounces (℥) = 1 pound (lb)

▶ *Apothecary Volume Equivalents*

60 minims (m) = 1 fluidram (fl ʒ)

8 fluidrams (fl ʒ) = 1 fluid ounce (fl ℥)

1 fluid ounce (fl ℥) = 480 minims (m)

16 fluid ounces (fl ℥) = 1 pint (pt)

▶ *Avoirdupois Equivalents*

1 ounce (oz) = 437.5 grains

16 ounces (oz) = 1 pound (lb)

▶ *Weight/Volume Equivalents*

1 mg/dL = 10 mcg/mL

1 mg/dL = 1 mg%

1 ppm = 1 mg/L

▶ *Conversion Equivalents*

1 gram (g) = 15.43 grains (gr)

1 grain (gr) = 64.8 milligrams (mg)

1 ounce (℥) = 31.1 grams (g)

1 ounce (oz) = 28.35 grams (g)

1 pound (lb) = 453.6 grams (g)

1 kilogram (kg) = 2.2 pounds (lb)

1 milliliter (mL) = 16.23 minims (m)

1 minim (m) = 0.06 milliliter (mL)

1 fluid ounce (fl oz) = 29.57 milliliters (mL)

1 pint (pt) = 473.2 milliliters (mL)

1 US gallon = 3.78 liters (L)

1 Canadian gallon = 4.55 liters (L)

0.1 milligram = 1/650 grain

0.12 milligram = 1/540 grain

0.15 milligram = 1/430 grain

0.2 milligram = 1/320 grain

0.3 milligram = 1/220 grain

0.4 milligram = 1/160 grain

0.5 milligram = 1/130 grain

0.6 milligram = 1/110 grain

0.8 milligram = 1/80 grain

1 milligram = 1/65 grain

▶ *Metric Length Conversion Equivalents*

2.54 cm = 1 inch

30.48 cm = 1 foot

1 m = 3.28 feet

1.6 km = 1 mile

ANTHROPOMETRICS

Creatinine Clearance Formulas

▶ *Formulas for Estimating Creatinine Clearance in Patients with Stable Renal Function*

Cockcroft-Gault Formula

Adults (age 18 years and older)[1]:

$$\text{CrCl (men)} = \frac{(140 - \text{age}) \times \text{weight}}{\text{SCr} \times 72}$$

$$\text{CrCl (women)} = 0.85 \times \text{above value}^*$$

---

*Some studies suggest that the predictive accuracy of this formula for women is better *without* the correction factor of 0.85.

where CrCl is creatinine clearance (in mL/min), SCr is serum creatinine (in mg/dL [or µmol/L divided by 88.4]), age is in years, and weight is in kilograms.

Traub-Johnson Formula

Children (age 1–18 years)[2]:

$$\text{CrCl} = \frac{0.48 \times \text{height} \times \text{BSA}}{\text{SCr} \times 1.73}$$

where BSA is body surface area (in m^2), CrCl is creatinine clearance (in mL/min), SCr is serum creatinine (in mg/dL [or µmol/L divided by 88.4]), and height is in centimeters.

▸ *Formula for Estimating Creatinine Clearance from a Measured Urine Collection*

$$\text{CrCl (mL/min)} = \frac{U \times V}{P \times T}$$

where U is the concentration of creatinine in a urine specimen in mg/dL, V is the volume of urine in mL, P is the concentration of creatinine in serum at the midpoint of the urine collection period in mg/dL, and T is the time of the urine collection period in minutes (eg, 6 hours = 360 minutes; 24 hours = 1440 minutes). Procedures for obtaining urine specimens should stress the importance of complete urine collection during the collection time period.

▸ *IDMS-Traceable MDRD Equation (Used for Creatinine Methods with Calibration Traceable to IDMS)*

For creatinine in mg/dL:

$$X = 175 \times \text{creatinine}^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

For creatinine in µmol/L:

$$X = 175 \times (\text{creatinine}/88.4)^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

where X is the glomerular filtration rate, constant for white men is 1 and for women is 0.742, and constant for African Americans is 1.212.

Ideal Body Weight

IBW is the weight expected for a non-obese person of a given height. The IBW formulas below and various life insurance tables can be used to estimate IBW. Dosing methods described in the literature may use IBW as a method in dosing obese patients.

Adults (age 18 years and older)[3]:

$$\text{IBW (men)} = 50 + (2.3 \times \text{height in inches over 5 ft})$$
$$\text{IBW (women)} = 45.5 + (2.3 \times \text{height in inches over 5 ft})$$

where IBW is in kilograms.

Children (age 1–18 years)[2] under 5-feet tall:

$$\text{IBW} = \frac{\text{height}^2 \times 1.65}{1000}$$

where IBW is in kilograms and height is in centimeters.

Children (age 1–18 years) 5 feet or taller:

$$\text{IBW (males)} = 39 + (2.27 \times \text{height in inches over 5 ft})$$
$$\text{IBW (females)} = 42.2 + (2.27 \times \text{height in inches over 5 ft})$$

where IBW is in kilograms.

Appendix C: Common Medical Abbreviations

These are the abbreviations used commonly in medical practice both in verbal communication and in the medical record.

A&O	alert and oriented
A&O×3	awake (or alert) and oriented to person, place, and time
A&O×4	awake (or alert) and oriented to person, place, time, and situation
A&P	active and present; anterior and posterior; assessment and plans; auscultation and percussion
A&W	alive and well
A1c	hemoglobin A1c
AA	aplastic anemia; Alcoholics Anonymous
AAA	abdominal aortic aneurysm
AAO	awake, alert, and oriented
AAO×3	awake and orientated to time, place, and person
ABC	absolute band counts; absolute basophil count; apnea, bradycardia, and cytology; aspiration, biopsy, and cytology; artificial beta cells
Abd	abdomen
ABG	arterial blood gases
ABO	blood group system (A, AB, B, and O)
ABP	arterial blood pressure
ABW	actual body weight
ABx	antibiotics
AC	before meals (*ante cibos*)
ACE	angiotensin-converting enzyme
ACE-I	angiotensin-converting enzyme inhibitor
ACLS	advanced cardiac life support
ACS	acute coronary syndromes
ACTH	adrenocorticotropic hormone
AD	Alzheimer disease; right ear (*auris dextra*)
ADA	American Diabetes Association; adenosine deaminase
ADE	adverse drug effect (or event)
ADH	antidiuretic hormone
ADHD	attention-deficit hyperactivity disorder
ADL	activities of daily living
ADR	adverse drug reaction
AF	atrial fibrillation
AFB	acid-fast bacillus; aortofemoral bypass; aspirated foreign body
AFEB	afebrile
AI	aortic insufficiency
AIDS	acquired immune deficiency syndrome
AKA	above-knee amputation; alcoholic ketoacidosis; all known allergies; also known as
AKI	acute kidney injury
ALFT	abnormal liver function test
ALL	acute lymphoblastic leukemia; acute lymphocytic leukemia
ALP	alkaline phosphatase
ALS	amyotrophic lateral sclerosis
ALT	alanine transaminase (SGPT); alanine aminotransferase
AMA	against medical advice; American Medical Association; antimitochondrial antibody
AMI	acute myocardial infarction
AML	acute myelogenous leukemia
Amp	ampule
ANA	antinuclear antibody
ANC	absolute neutrophil count
ANLL	acute nonlymphocytic leukemia
AODM	adult-onset diabetes mellitus
AOM	acute otitis media
AP	anteroposterior
APAP	acetaminophen (acetyl-*p*-aminophenol)
aPTT	activated partial thromboplastin time
ARB	angiotensin receptor blocker
ARC	AIDS-related complex
ARD	acute respiratory disease; adult respiratory disease; antibiotic removal device; aphakic retinal detachment
ARDS	adult respiratory distress syndrome
ARF	acute renal failure; acute respiratory failure; acute rheumatic fever
AROM	active range of motion
AS	left ear (*auris sinistra*)
ASA	aspirin (acetylsalicylic acid)
ASCVD	arteriosclerotic cardiovascular disease
ASD	atrial septal defect
ASH	asymmetric septal hypertrophy
ASHD	arteriosclerotic heart disease
AST	aspartate transaminase (SGOT); aspartate aminotransferase
ATG	antithymocyte globulin
ATN	acute tubular necrosis
AU	each ear (*auris uterque*)
AV	arteriovenous; atrioventricular; auditory visual
AVR	aortic valve replacement
BBB	bundle branch block; blood–brain barrier
BC	blood culture
BCOP	Board Certified Oncology Pharmacist
BCP	birth control pill
BCPP	Board Certified Psychiatric Pharmacist
BCPS	Board Certified Pharmacotherapy Specialist
BE	barium enema
BG	blood glucose
bid	twice daily (*bis in die*)
BKA	below-knee amputation
BM	bone marrow; bowel movement; an isoenzyme of creatine phosphokinase
BMC	bone marrow cells
BMD	bone mineral density
BMI	body mass index

BMP	basic metabolic panel
BMR	basal metabolic rate
BMT	bone marrow transplantation
BP	blood pressure
BPD	bronchopulmonary dysplasia
BPH	benign prostatic hyperplasia
bpm	beats per minute
BR	bed rest
BS	bowel sounds; breath sounds; blood sugar
BSA	body surface area
BUN	blood urea nitrogen
Bx	biopsy
C&S	culture and sensitivity
CA	cancer; calcium
CABG	coronary artery bypass grafting
CAD	coronary artery disease
CAH	chronic active hepatitis
CAM	complementary and alternative medicine
CAPD	continuous ambulatory peritoneal dialysis
CBC	complete blood count
CBD	common bile duct
CBG	capillary blood gas; corticosteroid-binding globulin
CC	chief complaint
CCA	calcium channel antagonist
CCB	calcium channel blocker
CCE	clubbing, cyanosis, edema
CCK	cholecystokinin
CCU	coronary care unit
CF	cystic fibrosis
CFS	chronic fatigue syndrome
CFU	colony-forming unit
CHD	coronary heart disease
CHF	chronic heart failure
CHO	carbohydrate
CI	cardiac index
CIWA	Clinical Institute Withdrawal Assessment
CK	creatine kinase
CKD	chronic kidney disease
CLL	chronic lymphocytic leukemia
CM	costal margin
CMG	cystometrogram
CML	chronic myelogenous leukemia
CMV	cytomegalovirus
CN	cranial nerve
CNS	central nervous system
C/O	complains of
CO	cardiac output; carbon monoxide
COLD	chronic obstructive lung disease
COPD	chronic obstructive pulmonary disease
CP	chest pain; cerebral palsy
CPAP	continuous positive airway pressure
CPK	creatine phosphokinase (BB, MB, and MM are isoenzymes)
CPP	cerebral perfusion pressure
CPR	cardiopulmonary resuscitation
CrCl	creatinine clearance
CRF	chronic renal failure; corticotropin-releasing factor
CRH	corticotropin-releasing hormone
CRI	chronic renal insufficiency; catheter-related infection
CRNA	Certified Registered Nurse Anesthetist
CRNP	Certified Registered Nurse Practitioner
CRP	C-reactive protein
CRTT	Certified Respiratory Therapy Technician
CSF	cerebrospinal fluid; colony-stimulating factor
CT	computed tomography; chest tube
cTnI	cardiac troponin I
CTZ	chemoreceptor trigger zone
CV	cardiovascular
CVA	cerebrovascular accident
CVC	central venous catheter
CVP	central venous pressure
Cx	culture; cervix
CXR	chest x-ray
CYP	cytochrome P450
D&C	dilatation and curettage
D_5W	5% dextrose in water
DBP	diastolic blood pressure
D/C	discontinue; discharge
DCC	direct-current cardioversion
DI	diabetes insipidus
DIC	disseminated intravascular coagulation
Diff	differential
DJD	degenerative joint disease
DKA	diabetic ketoacidosis
dL	deciliter
DM	diabetes mellitus
DNA	deoxyribonucleic acid
DNR	do not resuscitate
DO	Doctor of Osteopathy
DOA	dead on arrival; date of admission; duration of action
DOB	date of birth
DOE	dyspnea on exertion
DOT	directly observed therapy
DPGN	diffuse proliferative glomerulonephritis
DPI	dry powder inhaler
DRE	digital rectal examination
DRG	diagnosis-related group
DS	double strength
d/t	due to
DTP	diphtheria–tetanus–pertussis
DTR	deep tendon reflex
DVT	deep vein thrombosis
Dx	diagnosis
EBV	Epstein-Barr virus
EC	enteric coated
ECF	extracellular fluid
ECG	electrocardiogram
ECHO	echocardiogram
ECT	electroconvulsive therapy
ED	emergency department
EEG	electroencephalogram
EENT	eyes, ears, nose, throat
EF	ejection fraction
EGD	esophagogastroduodenoscopy
EIA	enzyme immunoassay
ECG	electrocardiogram
EMG	electromyogram
EMT	Emergency Medical Technician
Endo	endotracheal, endoscopy
EOMI	extraocular movements (or muscles) intact
EPO	erythropoietin
EPS	extrapyramidal symptoms
ER	emergency room
ERCP	endoscopic retrograde cholangiopancreatography
ERT	estrogen replacement therapy
ESKD	end-stage kidney disease
ESLD	end-stage liver disease
ESR	erythrocyte sedimentation rate
ESRD	end-stage renal disease
ET	endotracheal
EtOH	ethanol
FB	finger breadth; foreign body
FBS	fasting blood sugar
FDA	Food and Drug Administration

FEF	forced expiratory flow rate
FEV$_1$	forced expiratory volume in 1 second
FFP	fresh-frozen plasma
FH	family history
FiO$_2$	fraction of inspired oxygen
FOBT	fecal occult blood test
FPG	fasting plasma glucose
FPIA	fluorescence polarization immunoassay
FSH	follicle-stimulating hormone
FTA	fluorescent treponemal antibody
FT$_4$	free thyroxine
F/U	follow-up
FUO	fever of unknown origin
Fx	fracture
g	gram
G-CSF	granulocyte colony-stimulating factor
G6PD	glucose-6-phosphate dehydrogenase
GB	gallbladder
GBS	group B *Streptococcus*; Guillain-Barre syndrome
GC	gonococcus
GDM	gestational diabetes mellitus
GE	gastroesophageal; gastroenterology
GERD	gastroesophageal reflux disease
GFR	glomerular filtration rate
GGT	γ-glutamyl transferase
GGTP	γ-glutamyl transpeptidase
GI	gastrointestinal
GM-CSF	granulocyte-macrophage colony-stimulating factor
GN	glomerulonephritis; graduate nurse
gr	grain
GT	gastrostomy tube
gtt	drops (*guttae*)
GTT	glucose tolerance test
GU	genitourinary
GVHD	graft-versus-host disease
GVL	graft-versus-leukemia
Gyn	gynecology
H&H, H/H	hemoglobin and hematocrit
H&P	history and physical examination
HA	headache
HAART	highly active antiretroviral therapy
HAMD	Hamilton Rating Scale for Depression
HAV	hepatitis A virus
Hb, hgb	hemoglobin
HbAlc	glycosylated hemoglobin (hemoglobin Alc)
HBIG	hepatitis B immune globulin
HBP	high blood pressure
HBsAg	hepatitis B surface antigen
HBV	hepatitis B virus
HC	hydrocortisone, home care
HCG	human chorionic gonadotropin
HCO$_3$	bicarbonate
Hct	hematocrit
HCTZ	hydrochlorothiazide
HCV	hepatitis C virus
HD	Hodgkin disease; hemodialysis
HDL	high-density lipoprotein
HEENT	head, eyes, ears, nose, and throat
HF	heart failure
HFA	hydrofluoroalkane
H flu	*Hemophilus influenzae*
HGH	human growth hormone
HH	hiatal hernia
Hib	*Hemophilus influenzae* type b
HIT	heparin-induced thrombocytopenia
HIV	human immunodeficiency virus
HJR	hepatojugular reflux
HLA	human leukocyte antigen; human lymphocyte antigen
HMG-CoA	hydroxy-methylglutaryl coenzyme A
H/O	history of
HOB	head of bed
HPA	hypothalamic–pituitary axis
hpf	high-power field
HPI	history of present illness
HR	heart rate
H$_2$RA	H$_2$ receptor antagonist
HRSD	Hamilton Rating Scale for Depression
HRT	hormone-replacement therapy
HS	at bedtime (*hora somni*)
HSV	herpes simplex virus
HTN	hypertension
Hx	history
I&D	incision and drainage
I&O, I/O	intake and output
IBD	inflammatory bowel disease
IBW	ideal body weight
ICD	implantable cardioverter defibrillator
ICP	intracranial pressure
ICS	intercostal space; inhaled corticosteroid
ICU	intensive care unit
ID	identification; infectious disease
IDDM	insulin-dependent diabetes mellitus
IFN	interferon
Ig	immunoglobulin
IgA	immunoglobulin A
IgD	immunoglobulin D
IHD	ischemic heart disease
IJ	internal jugular
IM	intramuscular; infectious mononucleosis
INH	isoniazid
INR	international normalized ratio
IOP	intraocular pressure
IP	intraperitoneal
IPG	impedance plethysmography
IPN	interstitial pneumonia
IRB	institutional review board
ISA	intrinsic sympathomimetic activity
ISH	isolated systolic hypertension
IT	intrathecal
ITP	idiopathic thrombocytopenic purpura
IU	international units (this can be dangerous abbreviation because it may be read as "IV" for "intravenous")
IUD	intrauterine device
IV	intravenous; Roman numeral four; symbol for class 4 controlled substances
IVC	inferior vena cava; intravenous cholangiogram
IVDA	intravenous drug abuse
IVDU	injection drug use; intravenous drug use
IVF	intravenous fluids
IVIG	intravenous immunoglobulin
IVP	intravenous pyelogram; intravenous push
JODM	juvenile-onset diabetes mellitus
JRA	juvenile rheumatoid arthritis
JVD	jugular venous distension
JVP	jugular venous pressure
K	potassium
kcal	kilocalorie
KCl	potassium chloride
KOH	potassium hydroxide
KUB	kidney, ureter, and bladder
KVO	keep vein open
L	liter
LABA	long-acting beta agonist

LAD	left anterior descending; left axis deviation
LAO	left anterior oblique
LBBB	left bundle branch block
LBP	low-back pain
LDH	lactate dehydrogenase
LDL	low-density lipoprotein
LE	lower extremity
LES	lower esophageal sphincter
LFT	liver function test
LHRH	luteinizing hormone-releasing hormone
LLE	left lower extremity
LLL	left lower lobe
LLQ	left lower quadrant (abdomen)
LMD	local medical doctor
LMP	last menstrual period
LMWH	low-molecular-weight heparin
LOS	length of stay
LP	lumbar puncture
LPN	Licensed Practical Nurse
LPT	Licensed Physical Therapist
LR	lactated Ringer's
LS	lumbosacral
LT_4	levothyroxine
LUE	left upper extremity
LUL	left upper lobe
LUQ	left upper quadrant
LUTS	lower urinary tract symptoms
LVH	left ventricular hypertrophy
MAP	mean arterial pressure
MAR	medication administration record
MB-CK	a creatine kinase isoenzyme
mcg	microgram
MCH	mean corpuscular hemoglobin
MCHC	mean corpuscular hemoglobin concentration
MCV	mean corpuscular volume
MD	Medical Doctor
MDI	metered-dose inhaler
MDRD	modification of diet in renal disease
MEFR	maximum expiratory flow rate
mEq	milliequivalent
mg	milligram
MHC	major histocompatibility complex
MI	myocardial infarction; mitral insufficiency
MIC	minimum inhibitory concentration
mL	milliliter
MM	multiple myeloma; an isoenzyme of creatine phosphokinase
MMR	measles–mumps–rubella; midline malignant reticulosis
MOM	milk of magnesia
MPV	mean platelet volume
m/r/g	murmur/rub/gallop
MRI	magnetic resonance imaging
MRSA	methicillin-resistant *Staphylococcus aureus*
MRSE	methicillin-resistant *Staphylococcus epidermitis*
MS	mental status; mitral stenosis; musculoskeletal; multiple sclerosis; morphine sulfate
MSE	mental status exam
MSW	Master of Social Work
MTD	maximum tolerated dose
MTX	methotrexate
MVA	motor vehicle accident
MVI	multivitamin
MVR	mitral valve replacement; mitral valve regurgitation
MVS	mitral valve stenosis; motor, vascular, and sensory

N&V	nausea and vomiting
NAD	no acute (or apparent) distress
N/C	noncontributory; nasal cannula
NG	nasogastric
NGT	nasogastric tube; normal glucose tolerance
NIDDM	non–insulin-dependent diabetes mellitus
NIH	National Institutes of Health
NKA	no known allergies
NKDA	no known drug allergies
NHDA	nonketotic hyperosmolar acidosis
NL	normal
NOS	not otherwise specified
NPN	nonprotein nitrogen
NPO	nothing by mouth (*nil per os*)
NS	normal saline solution (0.9% sodium chloride solution); neurosurgery
NSAID	nonsteroidal anti-inflammatory drug
NSR	normal sinus rhythm
NSS	normal saline solution
NTG	nitroglycerin
NT/ND	nontender, nondistended
NVD	nausea/vomiting/diarrhea; neck vein distension; neovascularization of the disk; neurovesicle dysfunction; nonvalvular disease
N&V	nausea and vomiting
NYHA	New York Heart Association
O&P	ova and parasites
OA	osteoarthritis
OB	obstetrics
OCD	obsessive-compulsive disorder
OD	right eye (*oculus dexter*)
OGTT	oral glucose tolerance test
OPV	oral poliovirus vaccine
OR	operating room
OR×1	oriented to time
OR×2	oriented to time and place
OR×3	oriented to time, place, and person
OS	left eye (*oculus sinister*)
OSA	obstructive sleep apnea
OT	occupational therapy
OTC	over the counter
OU	each eye (*oculus uterque*)
P	pulse; plan; percussion; pressure
P&A	percussion and auscultation
P&T	peak and trough
PA	physician assistant; posteroanterior; pulmonary artery
PAC	premature atrial contraction
Paco_2	arterial carbon dioxide tension
Pao_2	arterial oxygen tension
PAOP	pulmonary artery occlusion pressure
PC	after meals (*post cibum*)
PCA	patient-controlled analgesia
PCI	percutaneous coronary intervention
PCKD	polycystic kidney disease
PCN	penicillin
PCP	*Pneumocystis carinii* pneumonia (also known as *Pneumocystis jirovecii* pneumonia); pneumocystis pneumonia; primary care physician; phencyclidine
PCWP	pulmonary capillary wedge pressure
PDE	paroxysmal dyspnea on exertion
PE	physical examination; pulmonary embolism
PEEP	positive end-expiratory pressure
PEFR	peak expiratory flow rate

PEG	percutaneous endoscopic gastrostomy; polyethylene glycol
Peg-IFN	pegylated interferon
PERL	pupils equal, reactive to light
PERRLA	pupils equal, round, and reactive to light and accommodation
PERRRLA	pupils equal, round, regular, and reactive to light and accommodation
PET	positron emission tomography
PFT	pulmonary function test
pH	hydrogen ion concentration
PH	past history; personal history; pinhole; poor health; pubic hair; public health
PHx	past history
PharmD	Doctor of Pharmacy
PID	pelvic inflammatory disease
PJD	*Pneumocystis jirovecii* pneumonia (also known as *Pneumocystis carinii* pneumonia)
PKU	phenylketonuria
PMH	past medical history
PMI	past medical illness; point of maximal impulse
PMN	polymorphonuclear leukocyte
PMS	premenstrual syndrome
PND	paroxysmal nocturnal dyspnea
Po	by mouth (*per os*)
Po$_2$	partial pressure of oxygen
POAG	primary open-angle glaucoma
POD	postoperative day
PPBG	postprandial blood glucose
ppd	packs per day
PPI	proton pump inhibitor
PPN	peripheral parenteral nutrition
PR	per rectum
PRBC	packed red blood cell
PRERLA	pupils round, equal, reactive to light and accommodation
PRN	when necessary, as needed (*pro re nata*)
PSA	prostate-specific antigen
PSH	past surgical history
PST	paroxysmal supraventricular tachycardia
PSVT	paroxysmal supraventricular tachycardia
PT	prothrombin time; physical therapy; patient
PTA	prior to admission; percutaneous transluminal angioplasty
PTCA	percutaneous transluminal coronary angioplasty
PTE	pulmonary thromboembolism
PTH	parathyroid hormone
PTSD	posttraumatic stress disorder
PTT	partial thromboplastin time
PUD	peptic ulcer disease
PVC	premature ventricular contraction
PVD	peripheral vascular disease
PVR	peripheral vascular resistance
PVT	paroxysmal ventricular tachycardia
q	every (*quaque*)
QA	quality assurance
qday	every day (*quaque die*)
QI	quality improvement
qid	four times daily (*quater in die*)
QNS	quantity not sufficient
qod	every other day
QOL	quality of life
QS	quantity sufficient
QTc	corrected QT interval
R&M	routine and microscopic
R&R	rate and rhythm
RA	rheumatoid arthritis; right atrium
RAAS	renin–angiotensin–aldosterone system
RBC	red blood cell
RCA	right coronary artery
RCM	right costal margin
RDA	recommended daily allowance
RDS	respiratory distress syndrome
RDW	red blood cell distribution width
REM	rapid eye movement; recent event memory
RES	reticuloendothelial system
RF	rheumatoid factor; renal failure; rheumatic fever
Rh	rhesus factor in blood
RHD	rheumatic heart disease
RLE	right lower extremity
RLL	right lower lobe
RLQ	right lower quadrant
RML	right middle lobe
RN	Registered Nurse
RNA	ribonucleic acid
R/O	rule out
ROM	range of motion
ROS	review of systems
RPh	Registered Pharmacist
RR	respiratory rate; recovery room
RRR	regular rate and rhythm
RRT	Registered Respiratory Therapist
RSV	respiratory syncytial virus
RT	radiation therapy
RUE	right upper extremity
RUL	right upper lobe
RUQ	right upper quadrant
RVH	right ventricular hypertrophy
S$_1$	first heart sound
S$_2$	second heart sound
S$_3$	third heart sound (ventricular gallop)
S$_4$	fourth heart sound (atrial gallop)
SA	sinoatrial
SABA	short-acting beta agonist
SAD	seasonal affective disorder
SAH	subarachnoid hemorrhage
Sao$_2$	arterial oxygen percent saturation
SBE	subacute bacterial endocarditis
SBFT	small bowel follow-through
SBGM	self-blood glucose monitoring
SBO	small bowel obstruction
SBP	systolic blood pressure
SC	subcutaneous; subclavian
SCr	serum creatinine
SEM	systolic ejection murmur
SG	specific gravity
SGOT (AST)	serum glutamic oxaloacetic transaminase (aspartate transaminase)
SGPT (ALT)	serum glutamic pyruvic transaminase (alanine transaminase)
SH	social history
SIADH	syndrome of inappropriate antidiuretic hormone secretion
SIDS	sudden infant death syndrome
SJS	Stevens-Johnson syndrome
SL	sublingual
SLE	systemic lupus erythematosus
SMA-6	sequential multiple analyzer for sodium, potassium, CO$_2$, chloride, glucose, and BUN
SMA-7	sequential multiple analyzer for sodium, potassium, CO$_2$, chloride, glucose, BUN, and creatinine
SMA-12	sequential multiple analyzer for glucose, BUN, uric acid, calcium, phosphorous, total protein, albumin, cholesterol, total bilirubin, alkaline phosphatase, SGOT, and LDH

SMA-23	includes the entire SMA-12 plus sodium, potassium, CO_2, chloride, direct bilirubin, triglyceride, SGPT, indirect bilirubin, R fraction, and BUN/creatinine ratio
SMBG	self-monitoring of blood glucose
SNF	skilled nursing facility
SNS	sympathetic nervous system
SOB	shortness of breath; see order book; side of bed
S/P	status post
SPF	sun protection factor
SQ	subcutaneous
SSKI	saturated solution of potassium iodide
SSRI	selective serotonin reuptake inhibitor
STAT	immediately; at once
STEMI	ST-segment elevated myocardial infarction
STD	sexually transmitted disease
SV	stroke volume
SVC	superior vena cava
SVRI	systemic vascular resistance index
SVR	supraventricular rhythm; systemic vascular resistance
SVT	supraventricular tachycardia
SW	social worker
Sx	signs
T	temperature
T_3	triiodothyroxine
T_4	thyroxine
T&A	tonsillectomy and adenoidectomy
T&C	type and crossmatch
TB	tuberculosis
TBG	thyroid-binding globulin
TBI	total-body irradiation; traumatic brain injury
TBW	total body weight
T bili	total bilirubin
TCA	tricyclic antidepressant
TCN	tetracycline
Tdap	tetanus, diphtheria, acellular pertussis vaccine
TEE	transesophageal echocardiogram
TFT	thyroid function test
TG	triglyceride
TIA	transient ischemic attack
TIBC	total iron-binding capacity
tid	three times daily (*ter in die*)
TLC	therapeutic lifestyle changes
TMJ	Temporomandibular joint
TMP-SMX	trimethoprim–sulfamethoxazole
TNTC	too numerous to count
TOD	target organ damage
TPN	total parenteral nutrition
TPR	temperature, pulse, respiration
T PROT	total protein
TSH	thyroid-stimulating hormone
TURP	transurethral resection of the prostate
Tx	treat, treatment
UA	urinalysis, uric acid
UC	ulcerative colitis
UE	upper extremity
UFH	unfractionated heparin
UGI	upper gastrointestinal
UOQ	upper outer quadrant
UPT	urine pregnancy test
URI	upper respiratory infection
USP	United States Pharmacopeia
UTI	urinary tract infection
UV	ultraviolet
VF	ventricular fibrillation
VLDL	very low-density lipoprotein
VO	verbal order
VOD	veno-occlusive disease
V_A/Q	ventilation–perfusion
VRE	vancomycin-resistant Enterococcus
VS	vital signs
VSS	vital signs stable
VT	ventricular tachycardia
VTE	venous thromboembolism
WA	while awake
WBC	white blood cell (count)
W/C	wheelchair
WDWN	well-developed, well-nourished
WHO	World Health Organization
WNL	within normal limits
W/U	workup
yo	year old
y	year

Appendix D: Glossary

2,3-Diphosphoglycerate: A compound in red blood cells that affects oxygen binding to and release from hemoglobin.

Ablation: Destruction of part or all of an organ or structure.

Acanthosis nigricans: Dark patches of skin with a thick, velvety texture; increased thickness and hyperpigmentation of the outer cell layers of the skin; typically observed at areas of flexure. Most commonly found in those who are overweight, have darker skin, and/or have diabetes or prediabetic conditions.

Acaricide: A chemical that kills mites and ticks.

Acetylcholine: Neurotransmitter at synapses in the ganglia of the visceral motor system and a variety of sites within the central nervous system.

Achalasia: Disorder in which the esophageal sphincter is impaired, preventing normal swallowing and often causing reflux of contents and a feeling that something is caught in the throat.

Achlorhydria: Absence of free hydrochloric acid in the stomach.

Acinar cells: The cells in the pancreas responsible for the synthesis, secretion, and storage of certain digestive enzymes.

Action potential: A rapid change in the polarity of the voltage of a cell membrane from negative to positive and back to negative; a wave of electrical discharge that travels across a cell membrane.

Acute coronary syndromes: Ischemic chest discomfort at rest most often accompanied by ST-segment elevation, ST-segment depression, or T-wave inversion on the 12-lead electrocardiogram; caused by plaque rupture and partial or complete occlusion of the coronary artery by thrombus. Acute coronary syndromes include myocardial infarction and unstable angina.

Acute interstitial nephritis: An acute inflammation of the kidney, often due to drugs; patients commonly present with fever, rash, and peripheral eosinophilia.

Acute rheumatic fever: Post-streptococcal immune sequelae occurring 2 to 3 weeks following inadequately treated throat infection with group A *Streptococcus*.

Addiction: A primary, chronic, neurobiologic disease with genetic, psychosocial, and environmental factors influencing its development and manifestations. Characterized by behaviors such as impaired control over substance use, compulsive use, continued use despite harm, and craving.

Adenoma: A nonmalignant tumor of the epithelial tissue that is characterized by glandular structures.

Adenomatous polyposis coli: A gene associated with familial adenomatous polyposis, an inherited disorder characterized by the development of myriad polyps in the colon, often occurring in adolescents and young adults ages 15 to 25.

Adjuvant chemotherapy: Treatment given after primary surgical treatment and designed to eliminate any remaining cancer cells that are undetectable, with the goal of improving survival.

Adjuvant therapy: Treatment that follows a definitive local therapy, usually surgery, to eradicate undetectable tumor cells and follows the primary modality with the intent of reducing the risk of disease relapse and prolonging survival. The ultimate goal is to cure patients who would not otherwise be cured by the primary modality alone.

Adrenalectomy: Surgical removal of an adrenal gland.

Adverse drug reaction: As defined by the American Society of Health-System Pharmacists, any unexpected, unintended, undesired, or excessive response to a medication that requires discontinuing the medication; changing the medication; modifying the dose (except for minor dosage adjustments); necessitates admission to the hospital; prolongs stay in a healthcare facility; necessitates supportive treatment; significantly complicates diagnosis; negatively affects prognosis; or results in temporary or permanent harm, disability, or death.

Aeroallergen: An airborne substance that causes an allergic response.

Afterload: The force against which a ventricle contracts that is contributed to by the vascular resistance, especially of the arteries, and by the physical characteristics (mass and viscosity) of the blood.

Ageism: Discrimination against aged persons.

Agoraphobia: Intense fear about situations (at least two different types) that escape would be difficult or help would be unavailable.

Air embolus: An obstruction in a small blood vessel caused by air that is introduced into a blood vessel and carried through the circulation until it lodges in a smaller vessel.

Akathisia: An extrapyramidal movement disorder presenting as a subjective sense of restlessness and difficulty in staying still (motor restlessness). Motor or subjective feelings of restlessness, often characterized by the urge to move limbs and inability to sit still.

Akinesia: Lack of movement.

Allodynia: Pain that results from a stimulus that does not normally cause pain.

Allogeneic: A transplant taking cells from one person and donating them to another.

Allograft: Tissue or organ transplanted from a donor of the same species but different genetic makeup; recipient's immune system must be suppressed to prevent rejection of the graft.

Allograft survival: After the transplant procedure, when the transplanted organ continues to have some degree of function, from excellent to poor.

Allorecognition: Recognition of the foreign antigens present on a transplanted organ or the donor's antigen presenting cells.

Alopecia: Hair loss.

α_2 autoreceptors: These adrenergic type receptors are located on norepinephrine neurons and respond to norepinephrine. These receptors function as a negative feedback loop such that stimulation inhibits the release of norepinephrine and thus blockade would result in release.

α_2 heteroreceptors: These adrenergic type receptors are located on serotonin neurons and respond to serotonin. These receptors function as a negative feedback loop such that stimulation inhibits the release of serotonin and thus blockade would result in release.

Ambulatory esophageal reflux monitoring: A telemetry capsule containing a tiny camera is swallowed, or a transnasal catheter is inserted to determine how often reflux is occurring as well as the incidence of abnormal esophageal acid exposure. The telemetry capsule provides about 48 hours of data, whereas the transnasal catheter provides about 24 hours of data.

Amenorrhea: Abnormal cessation or absence of menses; absence or discontinuation of regular menstrual periods.

Amotivation: Apathy, loss of effectiveness, and diminished capacity or willingness to carry out complex, long-term plans, endure frustration, concentrate for long periods, follow routines, or successfully master new material.

Ampulla of Vater: Dilation of the duodenal wall at the opening of the fused pancreatic and common bile ducts.

Amylin: A 37-amino acid polypeptide hormone secreted from the β-cells of the pancreas in response to nutrients. Mechanisms of action include slowing gastric emptying, suppressing postmeal glucagon secretion, and suppressing appetite.

Amyloid: Any of a group of chemically diverse proteins that are composed of linear nonbranching aggregated fibrils.

Analgosedation: A practice of utilizing analgesics first to treat pain and sedation.

Anaphylactic/anaphylaxis: Immediate, severe, potentially fatal hypersensitivity reaction induced by an antigen.

Anaphylactoid: An anaphylactic-like reaction, similar in signs and symptoms but not mediated by IgE. The drug causing this reaction produces direct release of inflammatory mediators by a pharmacological effect.

Anastomosis: A surgical connection between two structures that are not normally connected, often between two blood vessels; connection of two hollow organs to restore continuity after resection.

Androgen deprivation therapy: Agents such as LHRH agonists, GnRH antagonist, and antiandrogens that are used to suppress testosterone levels to that consistent with medical castration (testosterone levels < 50 ng/mL).

Anergy: A reduction or lack of an immune response to a specific antigen.

Aneurysm: A blood-filled bulge which forms in the wall of a weakened blood vessel; if ruptured, it may result in bleeding, shock, and/or other negative health outcome including mortality.

Angioedema: Swelling similar to urticaria (hives), but the swelling occurs beneath the skin instead of on the surface; characterized by deep swelling around the eyes and lips and sometimes of the hands and feet. If it proceeds rapidly, it can lead to airway obstruction and suffocation, and should therefore be treated as a medical emergency.

Angiogenesis: The formation of new blood vessels. Increased blood flow to deliver nutrients is required for tumor growth.

Angiography: Examination of blood vessels using X-rays after injection of a radiopaque substance.

Anosmia: Loss of smell.

Anovulatory cycle: A menstrual cycle where ovaries fail to produce, mature or release an egg.

Anterior circulation: Blood supply to the anterior section of the brain supplied by the internal carotid arteries, anterior cerebral artery, and middle cerebral artery.

Anterograde amnesia: Inability to remember new information; may be caused by neurodegenerative disorders or medications such as benzodiazepines.

Anticitrullinated protein antibodies: Antibodies directed against cyclic citrullinated peptide, a circular peptide (a ring of amino acids) containing the amino acid citrulline.

Anticoagulant: Any substance that inhibits, suppresses, or delays the formation of blood clots. These substances occur naturally and regulate the clotting cascade. Several anticoagulants have been identified in a variety of animal tissues and have been commercially developed for medicinal use.

Antinuclear antibodies: Autoantibodies that interact with components of cellular nuclei and DNA often presenting in connective tissues disorders.

Antiphospholipid syndrome: The association of thrombosis and/or pregnancy morbidity with antiphospholipid antibodies.

Antiprotease: A substance that inhibits the enzymatic activity of a protease.

Aortic dissection: A serious condition in which there is a tear in the wall of the aorta.

Aortic stenosis: A condition in which the aortic valve becomes thickened or calcified leading to a narrowing of the aortic valve opening and restriction of blood flow from the left ventricle.

Aphakic: The absence of a lens in the eye.

Aphasia: Impairment of language affecting the ability to speak and to understand speech; the loss of a previously held ability to speak or understand spoken or written language due to disease or injury of the brain.

Aphthous ulcer: A small superficial area of ulceration within the gastrointestinal mucosa, typically found in the oral cavity.

Aplasia cutis: A congenital defect consisting of circumscribed absence of skin involving usually the scalp and has been attributed to certain medications such as methimazole.

Apoptosis: Programmed cell death as signaled by the nuclei in normally functioning cells when age or state of cell health and condition dictates.

Arcuate scotoma: An arc-shaped area of blindness in the visual field.

Arteriovenous malformation: A tangle of blood vessels, usually in the brain, that results in abnormal connections between arteries and veins; if ruptured, it may result in hemorrhage.

Arthrocentesis: Puncture and aspiration of a joint. Certain drugs can be injected into the joint space for a local effect.

Ascites: Accumulation of fluid within the peritoneal cavity.

Asterixis: A flapping tremor of the arms and hands seen in patients with end-stage liver disease.

Astringent: A substance that causes tissues to constrict, resulting in a drying effect of the skin.

Atelectasis: Decreased or absent air in a partial or entire lung, with resulting loss of lung volume.

Atherosclerosis: Accumulation of lipids, inflammatory cells, and cellular debris in the subendothelial space of the arterial wall.

Atherosclerotic cardiovascular disease: Disease in which plaque builds up in vessels.

Atopic march: Describes the development of allergic diseases (eg, atopic dermatitis, allergic rhinitis, asthma) that often start at a young age.

Atopy: A genetic predisposition to develop allergic diseases.

Atresia: Congenital absence of a normal opening or normally patent lumen.

Atrial depolarization: Change in the membrane potential of an atrial myocyte, resulting in loss of polarization. Under normal conditions, depolarization of atrial myocytes is followed by atrial contraction.

Atrophic urethritis: Thinning and inflammation of the vaginal walls secondary to decline in estrogen, experienced by almost 50% of postmenopausal women.

Atypical femoral fracture: Stress fracture occurring in the long straight portion of the femur.

Augmentation: A complication in which symptoms worsen from dopaminergic therapy in restless legs syndrome.

Aura: Visual, but sometimes sensory, motor, or verbal disturbance usually occurring before a migraine or seizure.

Auspitz sign: Pinpoint bleeding that occurs when a psoriasis scale or lesion is peeled off of the skin.

Autologous: A transplant using one's own stem cells.

Avolition: Loss of motivation.

Azoospermic: Having no living spermatozoa in the semen, or failure of spermatogenesis.

Barium enema: A diagnostic test using an X-ray to view the lower gastrointestinal tract (colon and rectum) after rectal administration of barium sulfate, a chalky liquid contrast medium.

Barrett esophagus: A change of the normal squamous epithelium of the distal esophagus to a metaplastic, columnar-lined epithelium, usually caused by prolonged exposure of the esophageal mucosa to gastric acid. The condition is associated with an increased risk of developing esophageal cancer.

Basal Ganglia: Cluster of nerve cells deep in the brain that coordinate normal movement.

Bence-Jones proteins: Light-chained immunoglobulins found in the urine.

β-hydroxybutyric acid: A ketone body that is elevated in ketosis is synthesized in the liver from acetyl-coenzyme A and can be used as an energy source by the brain when blood glucose is low.

B_2 microglobulin: A low molecular weight protein that may be elevated in multiple myeloma.

Bilateral learning: Learning relationship where two people can simultaneously learn from each other.

Bilateral salpingo-oophorectomy: Surgical excision (removal) of both ovaries and the fallopian tubes.

Bile acids: The organic acids in bile, the yellowish-brown or green fluid secreted by the liver and discharged into the duodenum where it aids in the emulsification of fats, increases peristalsis, and retards putrefaction.

Biliary sludge: A deposit of tiny stones or crystals made up of cholesterol, calcium bilirubinate, and other calcium salts. The cholesterol and calcium bilirubinate crystals in biliary sludge can lead to gallstone formation.

Biopsy: The removal of cells or tissue for examination.

Bladder hypotonicity: Low elastic tension of the bladder.

Blast: An immature cell.

Blood urea nitrogen (BUN): A waste product in the blood produced from the breakdown of dietary proteins. The kidneys filter blood to remove urea and maintain homeostasis; a decline in kidney function results in an increase in BUN.

Body habitus: Body physique or build; describes the physical characteristics of the individual.

Body mass index: A calculation utilized to correct weight changes for height and is a direct calculation regardless of gender. It is the result of the weight in kilograms divided by the height in meters squared. If nonmetric measurements are used, it is the result of the weight in pounds multiplied by 703 and then that quantity divided by the product of height in inches squared.

Borborygmus: Rumbling or gurgling noises in the abdomen caused by movement of gas and fluid in the intestines.

Bouchard nodes: Hard, bony enlargement of the proximal interphalangeal (middle) joint of a finger or toe.

Boutonniere deformity: Joint deformity associated with rheumatoid arthritis that presents as flexion of the proximal interphalangeal (PIP) joints with hyperextension of the distal interphalangeal (DIP) joints.

Brachial plexus: Collection of nerves that arises from the spine at the base of the neck from nerves that supply parts of the shoulder, arm, forearm, and hand.

Brachytherapy: A form of radiotherapy where a sealed radiation source is placed inside or next to the area requiring treatment.

Bradycardia: Slower than normal heart rate.

Breakpoint: In antimicrobial therapy, the concentration of the antimicrobial agent that can be achieved in serum after a normal or standard dose of that agent.

Bronchiectasis: Chronic dilation of bronchi or bronchioles as a result of inflammatory disease or obstruction associated with heavy sputum.

Bronchoscopy: A specialized procedure that inserts a lighted instrument (bronscope) through the nose or mouth and into the lungs to exam the lungs.

Bullectomy: Surgical removal of one or more bullae (air spaces in the lung measuring > 1 cm in diameter in the distended state).

Burst suppression: Electroencephalography pattern characterized by electrical brain activity alternating with periods of no activity.

Calcitonin: A hormone produced by the parafollicular cells of the thyroid gland; involved in helping regulate levels of calcium and phosphate in the blood.

Calculi: The plural of calculus; stones (eg, kidney stones).

Campylobacter: Gram-negative bacillus often associated with traveler's diarrhea.

Capillary leak: Loss of intravascular volume into the interstitial space within the body.

Carcinogenesis: Production or origin of cancer.

Carcinoma: A cancerous tumor of the epithelial tissue of an organ; a malignant growth that arises from epithelium, found in skin or the lining of body organs. Carcinomas tend to infiltrate into adjacent tissue and spread to distant organs.

Carcinomatosis: Condition of having widespread dissemination of carcinoma (cancer) in the body.

Cardiac cachexia: Physical wasting with loss of weight and muscle mass caused by cardiac disease; a wasting syndrome that causes weakness and a loss of weight, fat, and muscle.

Cardiac index: Cardiac output normalized for body surface area (cardiac index = cardiac output/body surface area).

Cardiac output: The volume of blood ejected from the left side of the heart per unit of time: Cardiac output (L/min) = Stroke volume (L) × heart rate (beats/min).

Cardiac remodeling: Genome expression resulting in molecular, cellular, and interstitial changes and manifested clinically as changes in size, shape, and function of the heart resulting from cardiac load or injury.

Cardiomyopathy: Diseases of the heart muscle in which the heart muscle becomes enlarged, thick, or rigid.

Carotid bruit: Abnormal sound heard when auscultating a carotid artery caused by turbulent blood flow, usually due to the presence of atherosclerotic plaques.

Carotids: The two main arteries in the neck.

Castration-resistant prostate cancer: Prostate cancer that continues to progress despite suppression of typical hormonal growth signals (ie, despite androgen deprivation that achieves castration levels of testosterone).

Castration-sensitive prostate cancer: Prostate cancer that is controlled by typical hormonal growth signals (ie, despite androgen deprivation that achieves castration levels of testosterone). Also often referred to as castration-naive prostate cancer.

Cataplexy: Weakness or loss of skeletal muscle tone in the jaw, legs, or arms that is elicited by emotion (eg, anger, surprise, laughter, or sadness).

Causalgia: Persistent burning pain, allodynia, and hyperpathia following a traumatic nerve lesion.

Central pain: Pain that results from a lesion or dysfunction in the central nervous system.

Cervical adenopathy: Enlargement of cervical lymph nodes in the neck.

Cervicitis: Inflammation of the cervix.

Chemokines: Any of a group of cytokines produced by various cells that stimulate chemotaxis in white blood cells.

Chemokine receptor: Transmembrane or G-protein coupled receptors that upon binding of a chemokine, initiates an intracellular immune signaling cascade.

Chemoprevention: The use of drugs, vitamins, or other agents to reduce the risk of or delay the development or recurrence of cancer; clinical application of pharmacologic agents to reduce the risk of developing certain malignancies.

Chemoprophylaxis: Use of a medication (or chemical agent) to prevent disease.

Chemoreceptor trigger zone: A location in the area postrema of the fourth ventricle of the brain. It is exposed to cerebrospinal fluid and blood and is easily stimulated by circulating toxins to induce nausea and vomiting.

Chemosis: Edema of the bulbar conjunctiva.

Cheyne-Stokes respiration: Pattern of breathing with gradual increase in depth (and sometimes in rate) to a maximum, followed by a decrease resulting in apnea; the cycles ordinarily are 30 seconds to 2 minutes in duration, with 5 to 30 seconds of apnea.

Chikungunya: Mosquito-borne disease with a clinical syndrome of systemic fevers and arthritis.

Chimeric: An individual, organ, or substance composed of substances with different genetic origins.

Chloasma: Melasma characterized by irregularly shaped brown patches on the face and other areas of the skin, often seen during pregnancy or associated with the use of oral contraceptives.

Chlorpromazine equivalents: Approximate dose equivalent of a first-generation antipsychotic to 100 mg of chlorpromazine (relative potency).

Cholangitis: Inflammation of the bile duct system.

Cholecystitis: Inflammation of the gall bladder.

Cholelithiasis: Formation of stones in the gallbladder (gallstones).

Cholestasis: Reduced or lack of flow of bile, or obstruction of bile flow.

Cholesteatoma: A mass of keratinized epithelial cells and cholesterol resembling a tumor that forms in the middle ear or mastoid region.

Chorea: A type of dyskinesia with rhythmic dance-like movement. The increase in motor activity may be associated with fidgetiness, twitching, or flinging movements.

Chronotropic: Pertaining to the heart rate.

Chvostek's sign: Elicited by tapping on the proximal distribution of the facial nerve (adjacent to the ear). This will produce a brief spasm of the upper lip, eye, nose, or face in hypocalcemic patients.

Chylothorax: The presence of lymphatic fluid (chyle) in the pleural cavity.

Circadian rhythm: Natural, internal biological process that regulates the sleep–wake cycle every 24 hours.

Cirrhosis: Hepatic fibrosis and regenerative nodules that have destroyed the architecture of the liver, scarring the liver tissues. Progressive scarring of the liver results in nonfunctional hepatocytes.

Clonal expansion: An immunologic response in which lymphocytes stimulated by antigen proliferate and amplify the population of relevant T-cells.

Closed comedo: A plugged hair follicle of sebum, keratinocytes, and bacteria that remains beneath the surface of the skin. Also referred to as a "whitehead."

Clotting cascade: A series of enzymatic reactions by clotting factors leading to formation of a blood clot. The clotting cascade is initiated by several thrombogenic substances. Each reaction in the cascade is triggered by the preceding one, and the effect is amplified by positive feedback loops.

Clotting factor: Plasma proteins found in the blood that are essential to the formation of blood clots. Clotting factors circulate in inactive forms but are activated by their predecessor in the clotting cascade or a thrombogenic substance. Each clotting factor is designated by a Roman numeral (eg, factor VII) and by the letter "a" when activated (eg, factor VIIa).

Clubbing: Proliferation of soft tissues, especially in the nail bed, which results in thickening and widening of fingers and toes.

Coalescence: Fusion of smaller lipid emulsion particles forming larger particles, resulting in destabilization of the emulsion.

Cognitive deficits: An impairment in the mental process that affects the way a person interacts with their environment.

Colonocyte: Cell lining the colonic surface.

Colonoscopy: Visual examination of the colon using a lighted, lens-equipped, flexible tube (colonoscope) inserted into the rectum.

Comedolytic: An agent that can break up or destroy a comedo.

Comorbidities: Multiple disease states occurring concurrently in one patient.

Complete response: The disappearance of all signs of cancer in response to treatment.

Complex regimen: Taking medications three or more times per day, or 12 or more doses per day.

Concreteness: Inability to think in abstract terms; may be a primary developmental defect or secondary to organic mental disorder or schizophrenia.

Congenital adrenal hyperplasia: A rare inherited condition resulting from a deficiency in cortisol and aldosterone synthesis with resulting excess androgen production; clinical presentation depends on the variant of the condition but typically manifests as abnormalities in sexual development and/or adrenal insufficiency.

Conjunctivitis: Inflammation of the conjunctiva.

Conjunctival injection: Erythema of the conjunctiva.

Conjunctivitis medicamentosa: A drug-induced form of allergic conjunctivitis resulting from overuse of topical ocular vasoconstrictors.

Consolidation therapy: Treatment given after cancer has disappeared following the initial therapy; used to kill any cancer cells that may be left in the body.

Continuous positive airway pressure (CPAP): Main therapy for obstructive sleep apnea by producing a positive pressure column in the upper airway using room air.

Cor pulmonale: Right-sided heart failure caused by lung disease.

Corneal arcus: Accumulation of lipid on the cornea.

Coronary artery bypass graft surgery: Surgical intervention to improve coronary blood flow by removing a vein from the leg and attaching one end to the aorta and the other end to the coronary artery distal to the atherosclerotic plaque. Alternatively, an artery from the inside of the chest wall may be used to bypass the coronary occlusion.

Cosyntropin: A synthetic version of adrenocorticotropic hormone.

Counterirritant: A substance that elicits a superficial inflammatory response with the objective of reducing inflammation in deeper, adjacent structures.

C-peptide: Peptide made when proinsulin is split into insulin and C-peptide. They split before proinsulin is released from endocytic vesicles within the pancreas, one C-peptide for each insulin molecule. C-peptide is the abbreviation for "connecting peptide." It is used to determine if a patient has type 1 or type 2 diabetes mellitus.

Creaming: Aggregation of lipid emulsion particles that then migrate to the surface of the emulsion, can be reversed with mild agitation.

Creatinine: A waste product in the blood produced from the breakdown of protein by-products generated by muscle in the body or ingested in the diet. The kidneys filter blood to remove creatinine and maintain homeostasis; a decline in kidney function results in an increase in creatinine.

Crepitus: A grating sound or sensation typically produced by friction between bone-on-cartilage or bone-on-bone contact.

Critical care medicine: A medical practice that deals with life-threatening disease states or syndromes.

Cross-allergenicity: Sensitivity to one drug with activity to a different drug with a similar chemical structure.

Cross-cultural: Engagement involving persons from different cultures.

Crypt abscess: Neutrophilic infiltration of the intestinal glands (crypts of Lieberkühn); a characteristic finding in patients with ulcerative colitis.

Cutis laxa: Hypereflacidity of the skin with loss of elasticity.

Cyanosis: A dark blue or purple discoloration of the skin and mucous membranes due to deficient oxygenation of the blood.

Cyclooxygenase: An enzyme that catalyzes the conversion of arachidonic acid to prostaglandins and consists of two isoforms, generally abbreviated COX-1 and COX-2.

Cystocele: Herniation (abnormal protrusion) of the urinary bladder into the vagina.

Cysts: Nodules that harden into larger, pus-filled lesions.

Cytokines: Regulatory proteins, such as interleukins and lymphokines, that are released by cells of the immune system and act as intercellular mediators in the generation of an immune response.

Cytomegalovirus (CMV) disease: The term used when patients who are already infected with CMV present with the classically associated symptoms that resemble a viral infection and may include fever, malaise, arthralgias, and others.

Cytomegalovirus (CMV) infection: The term used when a patient has anti-CMV antibodies in the blood, when CMV antigens are detected in infected cells, or when the virus is isolated from a culture.

D test: Double-disk diffusion microbiological testing that indicates the presence or absence of macrolide-induced resistance to clindamycin.

Delayed peak response: The effects of a dose of medication take longer than expected to initiate.

Deliriogenic: To cause or promote increases in delirium.

Delirium: Transient brain syndrome presenting as disordered attention, cognition, psychomotor behavior, and perception.

Delirium tremens: Symptom of alcohol withdrawal characterized by hallucinations, delirium, severe agitation, fever, elevations of blood pressure and heart rate, and possible cardiac arrhythmias.

Dendritic cells: Immune regulating cells found in body tissues that serve as antigen-presenting cells.

Dengue: Mosquito-borne disease causing systemic fevers and hematologic abnormalities.

Dennie-Morgan line: A line or fold below the lower eyelids; associated with atopy.

Dermatophyte: Any microscopic fungus that grows on the skin, scalp, and nails.

Desquamation: Peeling or shedding of the epidermis (superficial layer of the skin) in scales or flakes.

Diabetes insipidus: Polyuria due to the failure of renal tubules to reabsorb water in response to antidiuretic hormone; an uncommon disorder that occurs when the kidneys pass an abnormally large volume of urine (3–20 quarts/day versus the typical 1–2 quarts/day) that is dilute and odorless ("insipid"). It is unrelated to diabetes mellitus, although both conditions cause frequent urination and constant thirst. Individuals with diabetes insipidus have normal blood glucose levels; however, their kidneys cannot balance fluid in the body.

Diabetic ketoacidosis: Reversible but life-threatening short-term complication primarily seen in patients with type 1 diabetes caused by the relative or absolute lack of insulin that results in marked ketosis and acidosis.

Dialysate: The physiologic solution used during dialysis to remove excess fluids and waste products from the blood.

Dialysis: The process of removing fluid and waste products from the blood across a semipermeable membrane to maintain fluid, electrolyte and acid–base balance in patients with kidney failure.

Diaphoresis: Sweating or profuse perspiration, generally as a symptom of a disease or an adverse drug effect.

Diarthrodial joint: A freely moveable joint (eg, knee, shoulder). Contrast with amphiarthrodial joint (a slightly movable joint; eg, vertebral joint) and synarthrodial joint (an unmovable joint; eg, fibrous joint).

Dientamoeba fragilis: Parasitic trichomonad associated with diarrheal illness in travelers.

Diffuse alveolar hemorrhage: Bleeding into the alveolar space of the lungs, resulting in hemoptysis, anemia, and diffuse alveolar infiltrates; a rare but life-threatening manifestation of systemic lupus erythematosus.

Dilated cardiomyopathy: Ability of the heart to pump blood is decreased because the left ventricle is enlarged and weakened.

Diphasic dyskinesia: Motor fluctuations occurring while plasma levodopa concentrations are rising and when they are falling. In each dosing interval, the patient may experience improvement, dyskinesia and improvement (IDI) or dyskinesia, improvement, dyskinesia (DID).

Direct current cardioversion: The process of administering a synchronized electrical shock to the chest, the purpose of which is to simultaneously depolarize all of the myocardial cells, resulting in restoration of normal sinus rhythm.

Disease progression: In cancer, at least a 20% increase in the sum of the longest diameter of target lesions from baseline, including new lesions discovered during treatment.

Disease-free survival: Period of time from the end of treatment that the patient survives without signs or symptoms of the disease.

Disseminated erythrosquamous papules: Widespread or whole body red, scaly psoriatic lesions.

DNA mismatch repair (dMMR) genes: Genes that control an intrinsic intracellular mechanism that corrects nucleotide insertion errors made during DNA replication, by excising the mismatched base pairs that escaped correction by the proofreading activities of DNA polymerases and replacing the mismatched bases with the correct ones.

Dose density: A chemotherapy treatment plan in which drugs are given with less time between treatments than in a standard chemotherapy treatment plan.

Dravet syndrome: Previously termed severe myoclonic epilepsy of infancy. Epilepsy syndrome that begins in infancy or early childhood with features of focal or generalized seizures that start before 15 months of age.

Ductus arteriosus: Shunt connecting the pulmonary artery to the aortic arch that allows blood from the right ventricle to bypass fetal lungs.

Duodenal enterocyte: Cells lining the duodenum, which is the first of three parts of the small intestine.

Dysarthria: Speech disorder due to weakness or incoordination of speech muscles; speech is slow, weak, and imprecise.

Dysesthesia: An unpleasant abnormal sensation.

Dyskinesia: Abnormal involuntary movements, which include dystonia, chorea, and akathisia.

Dyslipidemia: Elevation of the total cholesterol, low-density lipoprotein cholesterol or triglyceride concentrations, or a decrease in high-density lipoprotein cholesterol concentration in the blood.

Dysmenorrhea: Menstrual-associated crampy pelvic pain occurring with or just prior to menses. “Primary” dysmenorrhea implies pain in the setting of normal pelvic anatomy, while “secondary” dysmenorrhea is secondary to underlying pelvic pathology.

Dyspareunia: Pain during or after sexual intercourse.

Dyspepsia: Upper abdominal symptoms that may include pain or discomfort, bloating, feeling of fullness despite little food intake, unusual fullness after meals, nausea, loss of appetite, heartburn, regurgitation of food or acid, and belching.

Dysphagia: Painful or difficult swallowing, accompanied by a sensation of food being stuck in passage.

Dysphonia: Impairment of the voice or difficulty speaking.

Dyspnea: Difficult or labored breathing.

Dystonia: Disorder presenting with involuntary muscle contractions. Dystonias can also present as slow repetitive movements or abnormal postures. This is a type of dyskinesia. The movement is slow and twisting. It may be associated with painful muscle contractions or spasms.

Ebstein anomaly: Rare heart defect where the tricuspid valve is not formed properly in utero and blood leaks back into the right atrium; congenital heart defect in which the opening of the tricuspid valve is displaced toward the apex of the right ventricle. The severity can greatly vary from person to person.

Eburnation: A condition in which bone or cartilage becomes hardened and denser.

Ecchymosis: Passage of blood from ruptured blood vessels into subcutaneous tissue causing purple discoloration of the skin.

Eclampsia: Seizures associated with high blood pressure in a pregnant woman.

Ectopic pregnancy: Presence of a fertilized ovum outside of the uterine cavity.

Effector cells: Cells that become active in response to initiation of the immune response.

Electroconvulsive therapy (ECT): Administration of electric current to the brain through electrodes placed on the head in order to induce seizure activity in the brain, used in the treatment of certain mental disorders; ECT is a form of neurostimulation therapy in which patients are administered a controlled dose of electricity to induce a short, controlled seizure. Patients are unconscious and administered neuromuscular blockers to minimize movement.

Electroencephalography: The recording of brain waves via electrodes placed on the scalp or cortex.

Embolism: The sudden blockage of a vessel caused by a blood clot or foreign material which has been brought to the site by the flow of blood.

Embolization: Process by which a blood clot or foreign material dislodges from its site of origin, flows in the blood, and blocks a distant vessel.

Endometritis: Inflammation of the endometrium.

Endoscopy: A diagnostic tool used to examine the inside of hollow organs using a lighted, flexible instrument called an endoscope; refers to procedures such as gastroscopy, duodenoscopy, colonoscopy, and sigmoidoscopy.

Endothelial cell: A single layer of cells surrounding the lumen of arteries.

Endovascular: Procedures involving insertion of a catheter containing medications or instruments into a blood vessel for the treatment of vascular disease.

End-stage liver disease: Liver failure that is usually accompanied by complications such as ascites or hepatic encephalopathy.

Entamoeba histolytica: Most common cause of amoebic diarrhea in travelers.

Enteric fever/typhoid fever: Name of clinical syndrome associated with *Salmonella typhi*.

Enterotoxigenic *E. coli*: Gram-negative bacillus most commonly associated with traveler’s diarrhea.

Enthesitis: Inflammation of the sites where tendons, ligaments, or fascia attach to bone.

Enuresis: Involuntary discharge of urine.

Eosinophilic asthma: Subgroup of asthma with elevated sputum and blood eosinophils, thickening of the basement membrane zone, and corticosteroid responsiveness. Criteria that have been used for medications to treat eosinophilic asthma include blood eosinophil count ≥ 150 cells/μL (0.150 × 10^9/L), > 300 cells/μL (0.3 × 10^9/L), or 400 cells/μL (0.4 × 10^9/L) in the past year, sputum eosinophil count ≥ 3% (0.03), and exhaled nitric oxide concentration ≥ 50 ppb.

Epilepsy: A neurological disorder characterized by recurring motor, sensory, or psychic malfunction with or without loss of consciousness or convulsive seizures.

Epistaxis: Nasal hemorrhage with blood drainage through the nostrils; a nosebleed.

Erosive esophagitis: A severe form of gastroesophageal reflux disease in which the mucous membrane lining the esophagus is inflamed with areas of erosion resulting from abnormal reflux of gastric acid.

Erythrodermic psoriasis: Generalized erythema covering nearly the entire body surface area. Fever and malaise are common and while quite rare, can be severe and even fatal; it is usually associated with a worsening of other forms of psoriasis.

Erythematous: Flushing of the skin caused by dilation of capillaries. Erythema is often a sign of inflammation and infection.

Erythropoiesis stimulating agents: Agents developed by recombinant DNA technology that have the same biological activity as endogenous erythropoietin to stimulate erythropoiesis (red blood cell production) in the bone marrow.

Erythropoietin: A hormone primarily produced by the progenitor cells of the kidney that stimulates red blood cell production in the bone marrow. Lack of this hormone leads to anemia.

Esophageal manometry: Measurement of pressures and muscle contractions in the esophagus.

Esophageal stricture: Abnormal narrowing of the esophageal lumen.

Esophageal varices: Dilated blood vessels in the esophagus.

Essential fatty acid deficiency: Deficiency of linoleic acid, linolenic acid, and/or arachidonic acid, characterized by hair loss, thinning of skin, and skin desquamation. Long-chain fatty acids include trienes (containing 3 double-bonds [e.g., 5,8, 11-eicosatrienoic acid (or Mead acid), trienoic acids]) and tetraenes (containing 4 double-bonds [e.g., arachidonic acid]). Biochemical evidence of essential fatty acid deficiency includes a triene:tetraene greater than 0.2 and low linoleic or arachidonic acid plasma concentrations.

Essential medicines list: Medicines that satisfy the priority healthcare needs of the population that are selected and placed on a list by a group convened by the World Health Organization.

Euthymia: Normal or stable mood state.

Exanthem: Eruption of the skin.

Excess body weight: Calculated as the difference between actual and ideal body weight.

Excoriation: Recurrent skin picking resulting in lesions.

Exfoliative dermatitis: Severe inflammation and peeling of the entire skin surface due to a reaction to certain drugs.

Exploratory laparotomy: Surgical incision into the abdominal cavity, performed to examine the abdominal organs and cavity in search of an abnormality and diagnosis.

Extensive colitis: Inflammation that involves the majority of the colon in patients with inflammatory bowel disease.

External beam: An external source of radiation is pointed at a particular part of the body.

Extraction ratio: Fraction of the drug entering the liver in the blood that is irreversibly removed.

Extrapyramidal symptoms: Adverse effects of medications such as phenothiazine antipsychotics; types include dystonia (involuntary muscle contractions), tardive dyskinesia (repetitive, involuntary movements), parkinsonian symptoms (akinesia and tremors), and akathisia (motor restlessness or anxiety).

Extravasation: Movement of fluid from inside a blood vessel into the surrounding tissues.

Federal poverty level: A measure of income issued every year by the US Department of Health and Human Services; used to determine eligibility for certain government assistance programs and benefits.

Felty syndrome: An extra-articular manifestation of rheumatoid arthritis associated with splenomegaly and neutropenia.

Ferritin: A protein in the body that binds to iron; most of the iron stored in the body is bound to ferritin.

Festination: Walking with short, rapid, shuffling steps.

Fibrin: An insoluble protein that is one of the principal ingredients of a blood clot. Fibrin strands bind to one another to form a fibrin mesh. The fibrin mesh often traps platelets and other blood cells.

Fibrinolysis: A normal ongoing process that dissolves fibrin and results in the removal of small blood clots; hydrolysis of fibrin.

Fibroadenoma: A benign neoplasm which commonly occurs in breast tissue and is derived from glandular epithelium.

Fibrosis: Development of fibrous connective tissue in response to injury or damage.

Fluorescence in situ hybridization (FISH): A laboratory technique used to look at genes or chromosomes in cells and tissues. Pieces of DNA that contain a fluorescent dye are made in the laboratory and added to cells or tissues on a glass slide. When these pieces of DNA bind to specific genes or areas of chromosomes on the slide, they light up when viewed under a microscope with a special light.

Fistula: Abnormal connection between two internal organs (eg, arteriovenous fistula is a connection between an artery and a vein), or between an internal organ and the exterior or skin (e.g., enterocutaneous fistula is a connection between the intestine and the skin).

Fistulogram: X-ray photograph (or radiograph) taken after injection of a contrast material or radiopaque material (material that will not allow passage of x-rays and will be visible in an x-ray photograph, or radiograph).

Flexural psoriasis: Characterized by lesions found in skin folds that tend to be erythematous plaques which are often found in the axillary, genital, perineal, intergluteal, and inframammary regions. While shiny, smooth, and deep red in color, there may be skin fissures and the absence of the silvery scales.

Flight of ideas: A nearly continuous flow of rapid speech and thought that jumps from topic to topic, usually loosely connected.

Floppy iris or small pupil syndrome: A triad of pupillary constriction, iris prolapse, and billowing, which can complicate cataract surgery.

Flow cytometry: A method of measuring the number of cells in a sample, the percentage of live cells in a sample, and certain characteristics of cells, such as size, shape, and the presence of tumor markers on the cell surface. The cells are stained with a light-sensitive dye, placed in a fluid, and passed in a stream before a laser or other type of light. The measurements are based on how the light-sensitive dye reacts to the light.

Foam cell: Lipid-laden white blood cell.

Focal seizures: Seizures that start in a small area of the brain. They may stay localized or spread to involve larger areas or the entire brain.

Forced expiratory volume in the first second (FEV_1): The volume of air that a patient can forcibly exhale in the first second of forced exhalation after taking a maximal breath.

Forced vital capacity: The maximum volume of air that can be forcibly exhaled after taking a maximal breath.

Fraction of exhaled nitric oxide (FeNO): A noninvasive test that, when elevated, is an indicator of inflammation in the airways and likely responsiveness to inhaled corticosteroids.

Frailty: Excess demand imposed on reduced capacity; a common biological syndrome in the elderly.

Frank-Starling mechanism: Increase in stroke volume in response to an increase in volume of blood filling the heart (ie, end-diastolic volume) when all other factors remain constant.

Freezing: In Parkinson disease, a sudden but temporary inability to move.

French (scale): A scale used to measure the external diameter of a feeding tube.

Frequency (urinary): Eight or more micturitions in 24 hours.

Gallstone (cholelithiasis): A solid formation in the gallbladder or bile duct composed of cholesterol and bile salts.

Gamma knife: A type of radiation therapy that targets cancer cells within the head and brain with high precision. The treatment delivers intense radiation doses to the target area while sparing surrounding tissue.

γ-Aminobutyric acid (GABA): An inhibitory neurotransmitter.

Gastric bypass: A surgical procedure for weight loss that elicits its effectiveness through malabsorption and gastric volume limitation. The procedure involves full partitioning of the proximal gastric segment into a jejunal loop.

Gastritis: Inflammation of the stomach lining.

Gastroparesis: A form of autonomic neuropathy involving nerves of the stomach. It may include nausea, vomiting, feeling full, bloating and lack of appetite, and may cause wide fluctuations in blood sugars due to insulin action and nutrient delivery not occurring at the same time.

Gastrostomy: Operative placement of a new opening into the stomach, usually associated with feeding tube placement.

Generalized seizures: A seizure where the entire cerebral cortex is involved from the onset of the seizure.

Geniculate nucleus: The portion of the brain that processes visual information from the optic nerve and relays it to the cerebral cortex.

Geriatric syndrome: Age-specific presentations or differential diagnoses, including visual and hearing impairment, malnutrition and weight loss, urinary incontinence, gait impairment and falls, osteoporosis, dementia, delirium, sleep problems, and pressure ulcers; commonly seen conditions in elder patients.

Giardia: Protozoal gastrointestinal disease acquired by ingesting contaminated water.

Gleason score: System of histological grading used in prostate cancer. Individual scores range from 2 to 5. The two highest scores from each sample are combined for a total score (up to 10). Higher scores indicate higher-grade and more aggressive tumor.

Glomerular filtration rate: The volume of plasma that is filtered by the glomerulus per unit of time, usually expressed as mL/min or mL/min/1.73 m^2 (and in some areas in SI units of mL/s or mL/s/m^2), which adjusts the value for body surface area. This is the primary index used to describe overall renal function.

Glomerulonephritis: A general term for an inflammatory disease that affects the glomerulus of the kidney and is immunologically mediated. Glomerular lesions that are characterized by the inflammation of the capillary loops of the glomerulus. These lesions are generally caused by immunologic, vascular, or idiopathic diseases and lead to high blood pressure and possible loss of kidney function.

Glucagon: Hormone involved in carbohydrate metabolism produced by the pancreas and released when glucose levels in the blood are low. When blood glucose levels decrease, the liver converts stored glycogen into glucose, which is released into the bloodstream. The action of glucagon is opposite of insulin.

Gluconeogenesis: Formation of glucose from precursors other than carbohydrates especially by the liver and kidney using amino acids from proteins, glycerol from fats, or lactate produced by muscle during anaerobic glycolysis.

Glucose 6 phosphate dehydrogenase (G6PD) deficiency: A generally asymptomatic genetic condition known to cause life-threatening hemolysis when patients are prescribed certain medications or triggers; enzymatic deficiency that may result in hemolytic anemia when exposed to substrate that is metabolized by G6PD.

Glucosuria: Presence of glucose in the urine.

Glutamate: An excitatory amino acid found in the central nervous system.

Glycogenolysis: The process by which glycogen is broken down to glucose in body tissues.

Glycoprotein: A protein containing an attached carbohydrate chain.

Goiter: An enlargement of the thyroid gland, causing a swelling in the front part of the neck.

Gonioscopy: Examination of the anterior-chamber angle. A gonioprism or Goldman lens is used to perform gonioscopic evaluation.

Grandiosity: Exaggerated sense of self-importance, ideas, plans, or abilities.

Gut-associated lymphoid tissue: Lymphoid tissue, including Peyer patches, found in the gut that are important for providing localized immunity to pathogens.

Guttate psoriasis: Characterized a heavy or light sprinkling of teardrop-like, salmon-pink papules covered with a fine scale. These lesions are found primarily on the trunk and proximal extremities.

Gynecomastia: Excessive development of breasts in males.

Harm reduction: Interventions aimed at reducing the negative health or social consequences associated with substance use.

Hashimoto Disease: Condition in which the immune system attacks the thyroid gland; may result in hypothyroidism. Symptoms may include fatigue, weight gain, pale or puffy face, feeling cold, joint and muscle pain, constipation, dry and thinning hair, heavy menstrual flow or irregular periods, depression, a slowed heart rate, and problems getting pregnant and maintaining pregnancy. Occurs more commonly in women than in men.

Health literacy: Degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions.

Heavy menstrual bleeding: Prolonged menstrual bleeding lasting more than 7 days or cyclic, heavy menstrual bleeding (> 80 mL per cycle).

Heberden nodes: Hard, bony enlargement of the distal interphalangeal (terminal) joint of a finger or toe.

Hematemesis: Vomiting of blood.

Hematochezia: Passage of stool that is bright red or maroon, usually because of bleeding from the lower gastrointestinal tract.

Hematoma: A localized swelling in an organ or soft tissue that is filled with clotted or partially clotted blood resulting from a break in a blood vessel wall.

Hemiparesis: A slight paralysis or weakness on one side of the body.

Hemisensory deficit: Loss of sensation on one side of the body.

Hemithorax: A single side of the trunk between the neck and the abdomen in which the heart and lungs are situated.

Hemolytic anemia: Low hemoglobin resulting from hemolysis of red blood cells.

Hemoptysis: The expectoration of blood or blood-tinged sputum from the larynx, trachea, bronchi, or lungs.

Heparin-induced thrombocytopenia: A clinical syndrome of IgG antibody production against the heparin-platelet factor 4 complex occurring in approximately 1% to 5% of patients exposed to either heparin or low-molecular-weight heparin. Results in excess production of thrombin, platelet aggregation, and thrombocytopenia (due to platelet clumping), often leading to venous and arterial thrombosis, amputation of extremities, and death.

Hepatic encephalopathy: Confusion and disorientation experienced by patients with advanced liver disease due to the accumulation of ammonia in the bloodstream.

Hepatic steatosis: Accumulation of fat in the liver.

Hepatocellular carcinoma: Cancer of the liver.

Hepatorenal syndrome: Acute kidney injury occurring in individuals with disease of the liver or biliary tract due to decreased renal blood flow and conditions that damage both organs.

Hepatotoxicity: Toxicity to the liver causing damage to liver cells.

HER2 positive: Tumor positivity is defined by IHC (3+ when > 10% of the cells harbor complete membrane staining) and FISH (if the number of HER2 gene copies is ≥ 6, or the HER2/chromosome 17 ratio is ≥ 2).

Herniation: Abnormal protrusion of an organ through a defect or natural opening; for example, protrusion of the brain through the cranial wall.

Hesitancy (urinary): A decrease in the force of the stream of urine (usually the result of an obstruction or stricture between the bladder and the external urethral orifice).

Heterotopic: Placing a transplanted organ into an abnormal anatomic location.

Heterozygous: Having different alleles at a gene locus.

Hiatal hernia: Protrusion of a portion of the stomach through the esophageal hiatus of the diaphragm.

Hirsutism: Excessive body and facial hair, especially in a female.

Homeostenosis: Impaired capability to withstand stressors and decreased ability to maintain physiological and psychosocial homeostasis; a state commonly found in elderly.

Homozygous: Having identical alleles at a gene locus.

Hormone receptor positive: Expression of estrogen and/or progesterone receptors in breast cancer cells.

Hot flashes: A feeling of warmth that is commonly accompanied by skin flushing and mild-to-severe perspiration.

Human leukocyte antigens (HLA): Groups of genes found on the major histocompatibility complex that contain cell-surface antigen presenting proteins. The body uses HLA to distinguish between self cells and non–self cells.

Humoral: A substance that acts as a result of contact with targets for activity through blood or body fluids.

Hydronephrosis: Swelling of the renal pelvis and calyces of the kidney due to a back-up of urine due to obstruction.

Hyperalgesia: An exaggerated intensity of pain sensation.

Hypercalcemia: Excessive amount of calcium in the blood.

Hypercalciuria: Excessive amount of calcium in the urine.

Hypercapnia: Excessive carbon dioxide in the bloodstream, typically caused by inadequate respiration.

Hypercoagulable state: A disorder or state of excessive or frequent thrombus formation; also known as thrombophilia.

Hyperemesis gravidarum: A rare disorder of severe and persistent nausea and vomiting during pregnancy that can result in dehydration, malnutrition, weight loss, and hospitalization.

Hyperopia: Farsightedness.

Hyperglycemic hyperosmolar nonketotic syndrome: Severe increase in serum glucose concentration without the production of ketones, leading to an increase in serum osmolality and symptoms such as increased thirst, increased urination, weakness, fatigue, confusion, and in severe cases, convulsions and/or coma.

Hyperpigmentation: A common darkening of the skin, which occurs when an excess of melanin forms deposits in the skin.

Hypertrichosis: Excessive growth of hair.

Hypogammaglobulinemia: Low production of gamma globulins, resulting in reduced antibodies.

Hypogonadism: A medical condition resulting from or characterized by abnormally decreased functional activity of the gonads, with retardation of growth and sexual development. Associated with testosterone deficiency resulting from either testicular or pituitary/hypothalamic diseases.

Hypomania: Characterized by a persistently elevated, expansive, or irritable mood with related symptoms of increased goal-directed activity or energy including inflated self-esteem, decreased need for sleep, excessive talkativeness, racing thoughts, distractibility, and a propensity to be involved in high-risk activities with the symptoms lasting 4 to 6 days and does not require hospitalization or significant functional impairment.

Hypomimia: Lack of facial expression. Often termed masked face.

Hypophonia: Decreased voice volume.

Hypopituitarism: A clinical disorder characterized by complete or partial deficiency in pituitary hormone production.

Hyposmia: Reduced ability to smell.

Hypoxemia: Deficiency of oxygen in the blood.

Hypoxia: Deficiency of oxygen in body tissues.

Hysterectomy: Surgical removal of the uterus.

Immunoassay: A laboratory technique that uses the binding of antibodies to detect the presence or quantity of a certain substrate or antigen.

Immunoglobulin G index: The ratio of immunoglobulin G to protein in the serum or cerebrospinal fluid.

Immunophenotyping: A process used to identify cells, based on the types of antigens or markers on the surface of the cell. This process is used to diagnose specific types of leukemia and lymphoma by comparing the cancer cells to normal cells of the immune system.

Immunotherapy: A type of biological therapy that uses substances to stimulate or suppress the immune system to help the body fight cancer, infection, and other diseases.

Implantable cardioverter-defibrillator: A device implanted into the heart transvenously with a generator implanted subcutaneously in the pectoral area that provides internal electrical cardioversion of ventricular tachycardia or defibrillation of ventricular fibrillation.

Impulse control disorders: Urges and behaviors that are excessive and/or harmful to the individual or others; may include behaviors such as gambling, compulsive shopping or sexual behavior.

Incretin effect: A greater insulin stimulatory effect after an oral glucose load than that caused by an intravenous glucose infusion. The majority of the effect is thought to be due to glucose-dependent insulinotropic peptide (GIP) and glucagon-like peptide-1 (GLP-1). Patients with type 2 diabetes have a significant reduction of the incretin effect, implying these patients either have decreased concentration of incretin hormones, or a resistance to their effects. GLP-1 concentrations are reduced in patients with type 2 diabetes in response to a meal, while GIP concentrations are either normal or increased, suggesting a resistance to actions of GIP, thus making GLP-1 a more logical target for therapeutic intervention.

Induction: The first treatment given for a disease; often part of a standard set of treatments, such as surgery followed by chemotherapy and radiation.

Induction therapy: The first series of a treatment regimen typically designed to put a person into remission.

Infantile spasms (West syndrome): A seizure syndrome in infants younger than 1 year of age. It is characterized by a specific electroencephalogram pattern and spasms or jitters.

Initiation: In carcinogenesis, a cancer-causing substance encounters a normal cell to produce genetic damage, resulting in a mutated cell.

Inotropic: Relating to or influencing the force of muscular contractions.

In-stent restenosis: Complex process following stent implantation resulting in smooth muscle cell proliferation within an implanted stent, renarrowing of the arterial lumen, and recurrent ischemia.

Insulin resistance: Decreased response to insulin found before or early in the diagnosis of type 2 diabetes mellitus.

International normalized ratio (INR): Ratio of the patient's clotting time to the clinical laboratory's mean reference value, normalized by raising it to the international sensitivity index (ISI) power to account for differences in thromboplastin reagents. Therefore: INR = (patient's prothrombin time/laboratory's mean normal prothrombin time)^{ISI}.

Intra-articular: Administered to or occurring in the space within joints.

Intraperitoneal: Within the peritoneal cavity.

Intravesicular: Situated or occurring in the bladder.

Intussusception: The enfolding of one segment of the intestine within another.

Iontophoresis: Introduction of a medication into tissue through use of an electric current.

Ipsilateral: Occurring on the same side.

Irritant (venous): A drug that causes a burning sensation in the vein during intravenous administration; sometimes referred to as chemical phlebitis.

Ischemic penumbra: Ischemic, but still viable cerebral tissue. Typically, a rim of mild to moderately ischemic tissue in between normally perfused tissue and the area of evolving infarction; may remain viable for several hours.

Japanese encephalitis: A viral mosquito-borne disease endemic to Southeast Asia.

Jejunal entercocyte: Cells lining the jejunum, a section of the small intestine connecting the duodenum to the ileum.

Jejunostomy: Operative placement of a new opening into the jejunum, usually associated with feeding tube placement.

Juvenile myoclonic epilepsy: An epilepsy syndrome that typically occurs during teenage years and consists of generalized tonic-seizures and myoclonic jerks. Absence seizures may also occur with this syndrome.

Keratinization: The sloughing of epithelial cells in the hair follicle.

Keratinocytes: Predominant cell type in the outermost layer of the skin.

Keratitis: Infection of the cornea.

Keratoconjunctivitis sicca: An eye disease caused by eye dryness, which results from either decreased tear production or increased tear film evaporation. Also known as dry eye syndrome.

Kernicterus: A type of encephalopathy (brain disease or damage) as a result of high levels of bilirubin in the blood reaching the central nervous system.

Ketosis: Abnormal increase of ketone bodies present in conditions of reduced or disturbed carbohydrate metabolism.

Korotkoff sounds: The noise heard over an artery by auscultation when pressure over the artery is reduced below the systolic arterial pressure.

Kyphosis: Abnormal curvature of the spine resulting in protrusion of the upper back.

Lactose intolerance: The inability to digest lactose, a sugar found in milk products, resulting in diarrhea, bloating, and gas after ingestion.

Lagophthalmos: Poor closure of the upper eyelid.

Lamina cribrosa: Series of perforated sheets of connective tissue that the optic nerve passes through as it exits the eye.

Laminectomy: A type of surgery in which a surgeon removes part or all of the vertebral bone.

Laparoscopic: Abdominal exploration or surgery employing a type of endoscope called laparoscope.

Laparoscopic adjustable gastric banding: A surgical procedure for weight loss that elicits its effectiveness through gastric volume limitation; involves inserting a silicone band lined with an inflatable donut-shaped balloon around the neck of the stomach to be filled with isotonic liquid.

Laparotomy: Surgical opening of the abdominal cavity.

Laryngoscopy: Endoscopy of the larynx.

Left shift: An increase in the number of immature neutrophils. These immature cells may also be referred to as band neutrophils. Mature neutrophils may be referred to as segs.

Lennox–Gastaut syndrome: An epilepsy syndrome that often appears early in life that consists of a distinct electroencephalogram pattern, mild-to-severe developmental delay, and multiple seizure types.

Lesch-Nyhan syndrome: A rare inherited gene mutation that results in accumulation of abnormally high uric acid levels.

Leukocytoclastic vasculitis: Acute cutaneous vasculitis characterized by purpura (especially of the legs) and histologically by exudation of neutrophils and sometimes fibrin around dermal venules, with extravasation of red blood cells.

Leukocytosis: A condition in which the number of white blood cells circulating in the blood is increased.

Leukopenia: A condition where the number of circulating white blood cells are abnormally low due to decreased production of new cells, possibly in conjunction with medication toxicities.

Lewy bodies: Abnormal deposits of a protein called alpha-synuclein inside some nerve cells. They occur in a variety of locations, and their structure and composition vary depending on location.

Lhermitte sign: Tingling or shock-like sensation passing down the arms or trunk when the neck is flexed.

Libido: Sexual drive or desire.

Lichenification: Thickened, leathery, and hyperpigmented skin as a result of recurrent rubbing.

Ligament of Treitz: Landmark in the proximal portion of the jejunum beyond which it is preferred that postpyloric feedings be delivered for minimization of aspiration.

Linea nigra: Dark vertical line that appears on the abdomen during pregnancy.

Linear accelerator: A medical device that customizes high energy X-rays or electrons to conform to a tumor's shape and destroy cancer cells while sparing surrounding normal tissue.

Lipophilic: Having affinity for fatty substances.

Livedo reticularis: Purple mottling of the skin.

Low trauma fracture: A fracture resulting from a fall from standing height or less amount of trauma.

Lower esophageal sphincter: A manometrically defined zone of the distal esophagus with an elevated basal resting pressure that prevents the reflux of gastric material from the stomach. It relaxes on swallowing to permit the free passage of food into the stomach.

Lymphadenopathy: Enlargement greater than 1 cm of one or more lymph nodes.

Lymphatic: The network of vessels carrying tissue fluids.

Lymphoproliferative: Of or related to the growth of lymphoid tissue.

Macrocytosis: Enlargement of red blood cells with near-constant hemoglobin concentration.

Macrophage: A type of white blood cell that recognizes, surrounds, and ingests foreign particles and infectious microorganisms.

Maintenance therapy: The second phase of a treatment regimen, occurring after induction; typically designed to maintain remission.

Major malformation A defect that has either cosmetic or functional significance.

Maltodextrin: Easily digestible partially hydrolyzed starch.

Mania: Persistently elevated, expansive, or irritable mood with related symptoms of increased goal-directed activity or energy including inflated self-esteem, decreased need for sleep, excessive talkativeness, racing thoughts, distractibility, and a propensity to be involved in high-risk activities with the symptoms lasting at least a week or requiring hospitalization.

Mastalgia: Tenderness of the breast.

Mastodynia: Pain in the breast.

Maternal mortality ratio: The number of maternal deaths during a given time period per 100,000 live births during the same time period; highlights the risk of maternal deaths relative to the number of live births.

Matrix metalloproteinases: Any of a group of enzymes, normally located in the extracellular space of tissue, that function to break down proteins (eg, collagen) and require zinc or calcium atoms as cofactors for enzymatic activity. Responsible for the degradation of connective tissue.

Meatal stenosis: Narrowing in the opening of the urethra.

Meconium: First intestinal discharge ("stool") of a newborn infant, usually green in color and consisting of epithelial cells, mucus, and bile.

Mediastinal: Part of the chest that lies between the sternum and the spinal column, and between the lungs. This area contains the heart, large blood vessels, trachea, thymus gland, esophagus, and connective tissues.

Mediastinoscopy: A procedure that inserts a lighted instrument (mediastinoscope) used to examine the mediastinum.

Medication-assisted treatment: Use of medications with counseling and other behavioral therapies for the treatment of substance use disorders.

Melasma: Patchy skin pigmentation, often seen during pregnancy.

Melena: Abnormally dark black, tarry feces containing blood (usually from gastrointestinal bleeding).

Meningococcal: A term used to describe a disease caused by *Neisseria meningitidis* bacteria.

Menopause: Marked by final menstrual period due to loss of follicular activity and confirmed by 12 months of amenorrhea.

Mesial temporal lobe epilepsy: Involves medial or internal structures of the temporal lob and accounts for almost 80% of all temporal lobe seizures.

Mesocortical: A neural pathway that connects the ventral tegmentum to the cortex, particularly the frontal lobes. It is one of the major dopamine pathways in the brain.

Mesolimbic: One of the four major dopamine pathways in the brain, connecting the ventral tegmental area to the nucleus accumbens.

Mesothelioma: A benign or malignant tumor affecting the lining of the chest or abdomen. Commonly caused by exposure to asbestos fibers.

Metabolic Acidosis: A condition in the blood and tissues that is a consequence of an accumulation of lactic acid resulting from tissue hypoxia and anaerobic metabolism; may also be caused by a decrease in the concentration of alkaline compounds (typically bicarbonate).

Metabolic syndrome: Constellation of cardiovascular risk factors related to hypertension, abdominal obesity, dyslipidemia, and insulin resistance diagnosed by the presence of at least three of the following criteria: increased waist circumference, elevated triglyceride concentrations, decreased high density lipoprotein (HDL) cholesterol or active treatment to raise HDL cholesterol, elevated blood pressure or active treatment with antihypertensive therapy, or elevated fasting glucose or active treatment for diabetes.

Metastasis: Cancer that has spread from the original site of the tumor.

Methemoglobinemia: Condition caused by elevated levels of methemoglobin in red blood cells, resulting in enhanced oxygen affinity in heme sites and reduced oxygen delivery to tissues; leads to hypoxia, cyanosis, shortness of breath, mental status changes, and dizziness. In severe cases, it can lead to seizures, coma, or death.

Michaelis–Menten: Another term for zero-order pharmacokinetics. Drugs that follow zero-order pharmacokinetics reach saturation of metabolism within the usual dose ranges. This results in large changes in concentrations with small changes in doses.

Microalbuminuria: Urinary excretion of small but abnormal amounts of albumin. Confirmed spot urine albumin to creatinine ratio of 30 to 300 mg/g (3.4–34 mg/mmol creatinine) is consistent with microalbuminuria. Considered an early sign of chronic kidney disease.

Microcytosis: A condition in which the erythrocytes are smaller than normal.

Micrognathia: Abnormal smallness of the jaws.

Micrographia: Small handwriting, often seen in patients with Parkinson disease.

Microsatellite instability (MSI): The condition of genetic hypermutability that results from impaired DNA mismatch repair (MMR). The presence of MSI represents phenotypic evidence that MMR is not functioning normally.

Microvascular: Pertaining to the smaller vessels of the circulatory system such as capillaries, venules, and arterioles.

Microvascular pulmonary emboli: An obstruction in the small blood vessels in the lung caused by material (eg, blood clot, fat, air, foreign body) that is carried through the circulation until it lodges in another small vessel.

Micturition: Act of passing urine.

Minor malformation: Defect that has neither cosmetic nor functional significance.

Miosis: Pupil constriction.

Moebius syndrome: Rare congenital neurological disorder that is characterized by facial paralysis and affects eye movement.

Monoamine neurotransmitter: Serotonin, norepinephrine, and dopamine.

Monocyte: A large, phagocytic white blood cell that can further differentiate into macrophages or dendritic cells.

Monoparesis: Slight or incomplete paralysis affecting a single extremity or part of one.

Monosodium urate: A crystallized form of uric acid that can deposit in joints leading to an inflammatory reaction and signs and symptoms of gout.

Morphine equivalents: Dose of an opiate equivalency as it relates to morphine.

Mucositis: A complication of some cancer therapies in which the lining of the digestive system becomes inflamed. Often seen as sores in the mouth.

Multiparity: Condition of having given birth to multiple children.

Muscularis mucosa: The thin layer of smooth muscle found in most parts of the gastrointestinal tract.

Myalgia: Muscle aches or pains not necessarily associated with creatine kinase elevations.

Mydriasis: Pupil dilation.

Myelin: A protein and phospholipid sheath that surrounds the axons of certain neurons. Myelinated nerves conduct impulses more rapidly than nonmyelinated nerves.

Myelodysplastic syndrome: A type of cancer in which the bone marrow does not make enough healthy blood cells (white blood cells, red blood cells, and platelets) and there are abnormal cells in the blood and/or bone marrow.

Myelopathy: A neurologic deficit related to the spinal cord.

Myelosuppression: Reduction in white blood cells, red blood cells, or platelets.

Myocardial infarction: Myocardial cell death secondary to prolonged or severe local lack of oxygen supply (ischemia) to the myocardium; formation of an infarct, an area of tissue death, due to a local lack of oxygen.

Myoglobinuria: Presence of myoglobin in urine.

Myonecrosis: Necrotic damage to muscle tissue.

Myopathy: Unexplained muscle pain or weakness with creatine kinase elevations greater than 10 times the upper limit of normal.

Myringotomy: A surgical incision made in the tympanic membrane to relieve pressure and drain fluid from the middle ear.

Myxedema: Hypothyroidism characterized by a relatively hard edema of subcutaneous tissue, with increased content of proteoglycans in the fluid; characterized by somnolence, slow mentation, dryness and loss of hair, increased fluid in body cavities such as the pericardial sac, subnormal temperature, hoarseness, muscle weakness, and slow return of a muscle to the neutral position after a tendon jerk.

Nail psoriasis: Characterized by pitting, onycholysis, hyperkeratosis, and an oil-drop sign.

Nasal scotoma: Area of blindness in the nasal portion of peripheral vision.

Nasolacrimal occlusion: Closure of the tear duct to decrease systemic absorption of a drug.

Natriuresis: Excretion of sodium in the urine.

Necrotizing enterocolitis: Medical condition seen in premature infants, where portions of the bowel undergo necrosis.

Nelson syndrome: A condition characterized by the aggressive growth of a pituitary tumor and hyperpigmentation of the skin.

Neoadjuvant chemotherapy: Chemotherapy given before surgical resection to decrease tumor burden and make cancer more amenable to surgical resection.

Nephrolithiasis: A condition marked by the presence of renal calculi (stones) in the kidney or urinary system.

Nephron: The working unit of the kidney that filters blood to remove fluid, toxins and drugs. Each kidney contains approximately 1 million nephrons.

Nephrostomy: Narrow-gauge pigtail drain inserted into the renal pelvis for the purpose of draining urine.

Neuritic plaques: Extracellular deposits of amyloid beta with concentration markedly increased in the hippocampus, amygdala, and cerebral cortex. The plaque is thought to be formed through a cascade involving the formation of abnormally folded amyloid beta from amyloid precursor protein.

Neurofibrillary tangles: Aggregates of hyperphosphorylated tau protein, which can disrupt cellular function and lead to cellular degeneration and death.

Neuropathic pain: Pain resulting from a lesion or dysfunction of the nervous system.

Neuropathy: An abnormal and usually degenerative state of the nervous system or nerves. Damage to the small and large nerves due to glycation end products, lack of blood and nutrients to the nerves, or chemical imbalances.

Neurotransmitter: Chemical intermediary that carries messages between nerve cells.

Neutralizing antibodies: Antibodies that develop in response to a therapeutic agent that decreases the efficacy of the agent.

Nigrostriatal: One of the four main dopamine pathways in the brain, running from the substantia nigra to the caudate and putamen.

Nociception: Encoding and processing of noxious stimuli to the nervous system.

Nociceptors: Receptors for pain caused by injury from physical stimuli (mechanical, electrical, or thermal) or chemical stimuli (toxins); located in the skin, muscles, or in the walls of the viscera.

Nocturia: Excessive urination that occurs during sleep, causing patients to awaken overnight.

Nodule: An abnormal small swelling or aggregation of cells in the body.

Nonpolyposis: Absence of polyps.

Nonrapid eye movement sleep: The dreamless phases of sleep.

Non–ST-segment elevation myocardial infarction: A type of myocardial infarction that is limited to the subendocardial myocardium and is smaller and less extensive than an ST-segment elevation myocardial infarction.

Noradrenergic: Involving the transmission of norepinephrine.

Nulliparity: Condition of not having given birth to a child.

Nystagmus: Rapid, involuntary movements of the eyes.

Obtunded: Decreased level of consciousness.

Odynophagia: Pain on swallowing food and fluids, which is often due to esophageal disease.

Off time: In the context of Parkinson disease, the time when a Parkinson disease patient has poor control of their symptoms.

Off-label use: Use of a medication outside the scope of its approved, labeled use.

Oiling out: Continued coalescence of lipid emulsion particles, resulting in irreversible separation of the emulsion (also called "breaking" or "cracking" of the emulsion).

Oligoclonal immunoglobulin G bands: Small discrete bands in the gamma globulin region of fluid electrophoresis.

Oligohydramnios: Decreased amniotic fluid.

Oliguria: Reduced urine output; usually defined as less than 400 mL in 24 hours or less than 0.5 mL/kg/hour.

Omentumectomy: Excision of the double fold of peritoneum attached to the stomach and connecting it with abdominal viscera (omentum).

On time: In the context of Parkinson disease, the time when the Parkinson disease patient has good control of their symptoms.

Oncogene: A gene that is a mutated form of a gene involved in normal cell growth.

Open comedo: A plugged hair follicle of sebum, keratinocytes, and bacteria that protrudes from the surface of the skin and appears black or brown in color. Also referred to as a "blackhead."

Opportunity cost: The benefits foregone by selecting one alternative over another, for example, spending on healthcare reduces disposable income that may have been used on savings or investment.

Opsonization: The process by which an antigen is altered so as to become more readily and more efficiently engulfed by phagocytes.

Optic neuritis: Usually monocular central visual acuity loss and ocular/periorbital pain caused by demyelination of the optic nerve.

Oral glucose tolerance test: A test to measure the body's response to glucose; may be used to screen for type 2 diabetes and gestational diabetes.

Orchiectomy: Surgical removal of the testes.

Organification: Binding of iodine to tyrosine residues of thyroglobulin.

Orthopnea: Difficulty in breathing that occurs when lying down and is relieved upon changing to an upright position.

Orthostasis: Characterized by a drop in blood pressure when standing up from sitting or lying down, often causing light-headedness and dizziness.

Orthostatic hypotension/orthostasis: Significant blood pressure reduction upon standing due to the impairment of autonomic reflexes or depletion of intravascular volume.

Orthotopic: Placing a transplanted organ into the normal anatomic location.

Osmolality: A measure of the number of osmotically active particles per unit solution, independent of the weight or nature of the particle.

Osmolar gap: The difference between the measured serum osmolality and the calculated serum osmolality.

Osteoblasts: Cells that secrete the matrix for bone formation.

Osteoclasts: Cells involved in bone resorption.

Osteodystrophy: Defective bone growth, usually attributed to kidney disease or alterations in calcium and phosphorus metabolism.

Osteomalacia: Softening of the bones.

Osteonecrosis: Death of bone tissue.

Osteopenia: Reduced bone density or mass.

Osteophytes: Bony outgrowths (also called bone spurs) into the joint space.

Osteoporosis: Disease of the bones characterized by a loss of bone tissue, resulting in brittle, weak bones that are susceptible to fracture (porous bones).

Ostomy: Surgical operation where part of the abdominal wall is opened and part of the intestine is connected to the opening for intestinal draining (eg, colostomy, ileostomy).

Otalgia: Ear pain or earache.

Overall objective response rate: The proportion of patients with a complete response or partial response to anticancer treatment over a defined time period.

Ovulation: Periodic ripening and rupture of mature follicle and the discharge of ovum from the cortex of the ovary.

Palliative care: Pharmacological and nonpharmacological therapy intended to improve quality of life.

Palpable cord: Presence of an induration (cord) that is palpable, sometimes nodular, along the course of/or within an affected vein. Persistence of this cord when the extremity is raised suggests the presence of thrombus.

Pancreatitis: Inflammation of the pancreas.

Pancreatic pseudocyst: A cyst-like space not lined by epithelium and contained within the pancreas.

Panhypopituitarism: A clinical disorder characterized by complete deficiency in pituitary hormone production.

Pannus: Inflamed synovial tissue that invades and destroys articular structures.

Papilledema: Swelling of the optic disk/nerve due to increased intracranial pressure.

Papules: Solid, elevated lesion less than 0.5 cm in diameter.

Paracentesis: Removal of ascitic fluid from the peritoneal space.

Paracentral scotoma: Blind spots near the center of the visual field.

Parasomnias: Abnormal sleep behaviors such as sleep terrors and sleepwalking.

Parenchyma: The functional tissue of an organ as distinguished from connective and supporting tissue.

Parenteral nutrition: Delivery of nutrients via the intravenous route.

Paresthesia: An abnormal touch sensation, such as burning or prickling, that occurs without an outside stimulus.

Partial response: A decrease in the size of a tumor, or in the extent of cancer in the body, in response to treatment.

Paternalistic medicine: A philosophy of medicine that promotes the physicians' wishes above any other member of the health-care team or patients.

Peak expiratory flow: The maximum flow rate of air leaving the lungs upon forced exhalation. Individualized best measurements are established for each patient using a handheld peak flow meter.

Pelvic inflammatory disease: Inflammation of the endometrium, uterine tubes, and pelvic peritoneum; often due to a sexually transmitted infection.

Percutaneous coronary intervention: A minimally invasive procedure whereby access to the coronary arteries is obtained through either the femoral or radial artery up the aorta to the coronary ostia. Contrast media is used to visualize the coronary artery stenosis using a coronary angiogram. A guidewire is used to cross the stenosis and a small balloon is inflated to compress the atherosclerotic plaque and restore coronary artery blood flow. A stent is often deployed at the site to prevent acute closure and restenosis of the coronary artery. Newer stents are coated with antiproliferative drugs, such as paclitaxel, sirolimus, zotarolimus, or everolimus, which further reduce the risk of restenosis of the coronary artery.

Percutaneous endoscopic gastrostomy: Gastric feeding tube placed via endoscopic technique.

Percutaneous endoscopic jejunostomy: Jejunal feeding tube placed via endoscopic technique.

Pericarditis: Inflammation of the pericardium, the sac-like tissue that surrounds the heart.

Perihilar: The area surrounding the region where the bronchi, arteries, veins, and nerves enter and exit the lungs.

Perimenopause: Transitional period prior to menopause.

Perimetry: Measurement of the visual field.

Peripheral artery disease: Atherosclerosis of the peripheral arteries.

Peripheral vascular resistance: The sum of resistance to blood flow by systemic blood vessels.

Phagocytosis: The process of engulfing and ingesting an antigen by phagocytes.

Pharmacodynamics: Biochemical, physiologic, and molecular effects of drugs on the body.

Pharmacogenomics: The study of inherited genetic variations that dictate different drug responses. Pharmacogenomics explores the ways such variations can be used to predict responses to investigational products and plays an increasingly important role in drug discovery.

Pharmacokinetics: The movement of drug into, through, and out of the body.

Phenotype: The visible or observable properties of an organism that are produced by the interaction of the genotype and the environment.

Pheochromocytoma: A tumor arising from chromaffin cells, most commonly found in the adrenal medulla. The tumor causes the adrenal medulla to hypersecrete epinephrine and norepinephrine resulting in hypertension and other signs and symptoms of excessive sympathetic nervous system activity. The tumor is usually benign but may occasionally be cancerous.

Phlebitis: Inflammation of a blood vessel (e.g., vein).

Phobia: Excessive or unreasonable fear to a specific object (eg, people, animals) or situation (eg, flying), which are avoided or experienced with significant distress.

Photobiomodulation: Use of red or near-infrared light to stimulate healing, relieve pain and inflammation, and prevent tissue from dying.

Photochemotherapy: The use of psoralens in addition to ultraviolet rays for patients with a significant amount of body surface area affected (>10%).

Photodynamic therapy: Treatment with drugs that become active when exposed to light.

Photophobia: Intolerance to bright light.

Phototherapy: The use of ultraviolet rays for patients with a significant amount of body surface area affected (>10%).

Physical dependence: A state of adaptation that is manifested by a drug-class specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist.

Pilosebaceous unit: A hair follicle and the surrounding sebaceous glands.

Pica: An abnormal desire to eat substances (such as chalk or ashes) not normally eaten.

Plaque psoriasis: The most common form of psoriasis; manifests as well-defined, sharply demarcated, erythematous plaques typically covered with silvery scales. These plaques are irregular, round to oval in shape, and are almost always found on the scalp, trunk, buttocks, and limbs.

Plasma cell: Antibody-producing cells.

Plasmodium falciparum: The most common cause of clinical malaria globally and the cause of the most fatalities associated with malaria.

Plasmodium vivax: The most common cause of clinical malaria in the Americas. It is the species most commonly associated with a delayed onset of relapse after treatment.

Pleurisy: Chest pain upon inspiration occurring due to inflammation of the lining of the lungs.

Pleuritis: Inflammation of the lining (pleura) around the lungs.

Pneumatic otoscopy: A diagnostic technique involving visualization of the tympanic membrane for transparency, position, and color, and its response to positive and negative air pressure to assess mobility.

Pneumococcal: A term used to describe a disease caused by *Streptococcus pneumoniae* bacteria.

Pneumothorax: A condition that occurs when air leaks into the space between chest wall and lung. The air pocket exerts pressure against the lung causing it, or a portion of it, to “collapse”; often referred to as a collapsed lung.

Podagra: Gout of the foot, especially the first metatarsophalangeal joint.

Podocyte: Cells that make up the epithelial lining of Bowman’s capsule of the kidneys that surround the capillaries in the glomerulus. These cells are responsible for filtering blood in the glomerulus.

Polycystic ovary syndrome: Condition in which women have many small cysts on their ovaries that can lead to hormone imbalances and irregular periods.

Polycythemia: An abnormal increase in the number of erythrocytes in the blood.

Polycythemia vera: A hematologic cancer that is slow-growing in which the bone marrow produces excess red blood cells.

Polydipsia: Excessive thirst.

Polymerase chain reaction: A laboratory method used to make many copies of a specific DNA sequence.

Polymorphism: Occurrence in more than one form such as variance of genes.

Polyphagia: Eating excessively large amounts of food at a meal.

Polypharmacy: Taking multiple medications concurrently.

Polyps: Any growth or mass protruding from a mucous membrane.

Polysomnography: Specific type of sleep study that records brain waves, oxygen levels, heart rate, breathing, and eye and leg movements.

Polyuria: Excessive excretion of urine resulting in profuse micturition.

Posterior circulation: Blood supply to the posterior section of the brain through the vertebral, basilar, and posterior cerebral arteries (ie, brainstem, cerebellum, occipital lobe).

Post-intensive care syndrome: The disability noted after discharge from the intensive care unit and critical illness. Impairments which have been described include, but are not limited to, issues with cognition, mental health disabilities, and recurring physical ailments, specifically neuromuscular weakness.

Prader–Willi syndrome: A genetic disorder characterized by short stature, mental retardation, low muscle tone, abnormally small hands and feet, hypogonadism, and excessive eating leading to extreme obesity.

Prebiotic: Substance that can be used to nourish beneficial microbes in the gut.

Prediabetes: An asymptomatic but abnormal state that precedes the development of clinically evident diabetes.

Preload: The stretched condition of the heart muscle at the end of diastole just before contraction; volume in the left ventricle at the end of diastole estimated by the pulmonary artery occlusion pressure (also known as the pulmonary artery wedge pressure or pulmonary capillary wedge pressure).

Priapism: A prolonged, painful erection lasting more than 4 hours. Considered a medical emergency.

Primary amenorrhea: Absence of menses by age 15 in the presence of normal secondary sexual development or within 5 years of thelarche (if occurs before age 10).

Probiotic: Microorganisms administered to achieve a health benefit.

Proctitis: Inflammation confined to the rectum in patients with inflammatory bowel disease.

Proctosigmoiditis: Inflammation involving the sigmoid colon and rectum in patients with inflammatory bowel disease.

Progenitor: A primitive cell.

Prognostic factors: Biological or clinical markers associated with survival independent of therapy.

Progression-free survival: The length of time during and after the treatment of a disease, such as cancer, that a patient lives with the disease but it does not get worse. In a clinical trial, measuring the progression-free survival is one way to see how well a new treatment works.

Progressive multifocal leukoencephalopathy: A neurological disorder characterized by the destruction of myelin-producing cells.

Prolapse: The dropping, falling, sinking, or sliding of an organ from its normal position or location in the body.

Promotion: The stage of carcinogenesis in which existing tumors are stimulated to grow and survive.

Proptosis: Forward displacement of the eyeball.

Prostaglandin: Any of a large group of biologically active, carbon-20, unsaturated fatty acids that are produced by the metabolism of arachidonic acid through the cyclooxygenase pathway.

Prostate-specific antigen (PSA): Protein produced by columnar secretory cells in the prostate that plays a role in the liquefaction of seminal fluid. Serum PSA levels greater than 10 ng/mL are associated with prostate cancer.

Prostatectomy: Surgical removal of the prostate gland and tissues surrounding it.

Prostatism: A syndrome associated with outlet obstruction at the bladder neck and most commonly caused by benign prostatic hyperplasia.

Protease: Any of numerous enzymes that catalyze the breakdown of proteins.

Proteasome: A large protein complex that helps destroy other cellular proteins when they are no longer needed.

Protectant: An agent that forms an occlusive barrier between the skin and surrounding moisture.

Proteinuria: The presence of measurable amounts of protein in the urine, which is often indicative of structural glomerular or tubular damage in the kidney.

Proteoglycan: Any one of a class of glycoproteins of high molecular weight that are found in the extracellular matrix of connective tissue. They are made up mostly of carbohydrate consisting of various polysaccharide side chains linked to a protein and resemble polysaccharides rather than proteins with regard to their properties.

Proteosome: An enzyme complex that degrades intracellular proteins.

Prothrombin time: A measure of coagulation representing the amount of time required to form a blood clot after the addition of thromboplastin to the blood sample; also known as Quick test.

Prothrombotic state: A state of high coagulation of the blood.

Proto-oncogene: A gene involved in normal cell growth. Mutations (changes) in a proto-oncogene may cause it to become an oncogene, which can cause the growth of cancer cells.

Pruritus: Localized or generalized itching due to irritation of sensory nerve endings.

Pseudophakic: The presence of a lens after cataract extraction.

Pseudopolyp: An area of hypertrophied gastrointestinal mucosa that resembles a polyp and contains nonmalignant cells.

Psoralens: Compounds that act as photosensitizing compounds.

Psoriatic arthritis: Inflammatory arthropathy associated with psoriasis. This condition is characterized by stiffness, pain, swelling, and tenderness around the joints and ligaments.

Pulmonary artery catheter: An invasive device used to measure hemodynamic parameters directly, including cardiac output and pulmonary artery occlusion pressure; calculated parameters include stroke volume and systemic vascular resistance.

Pulmonary artery occlusion pressure: A hemodynamic measurement obtained via catheter placed into the pulmonary artery used to evaluate patient volume status within the left ventricle.

Pulmonary embolus: An obstruction of the pulmonary artery or one of its branches by material that originated elsewhere in the body. The embolic material is often either a thrombus, air, tumor, or adipose tissue.

Pulmonary hypertension: An elevation in the pulmonary arterial pressure that can lead to right ventricular failure and heart failure symptoms.

Pulse oximetry: A noninvasive method of measuring arterial oxygen saturation. A pulse oximeter is a small device placed on a finger or earlobe that reads reflected light from capillary blood and estimates oxygen saturation.

Pulsus paradoxus: A large fall in systolic blood pressure and pulse volume during inspiration or an abnormal variation in pulse volume during respiration in which the pulse becomes weaker with inspiration and stronger with expiration.

Punding: Stereotyped behavior with repetitive movement or actions. An adverse reaction to dopaminergic therapy.

Purkinje fibers: Specialized myocardial fibers that conduct impulses from the atrioventricular node to the ventricles.

Purpura: A small hemorrhage of the skin, mucous membrane, or serosal surface.

Purulent: Containing, consisting of, or being pus.

Pustular psoriasis: A type of psoriasis associated with collection of neutrophils great enough to be seen clinically; may be generalized or localized. Often characterized by widespread sterile pustules and erythema.

Pustules: Vesicles filled with purulent fluid less than 0.5 cm in diameter.

Quality indicators: A list of indicators used by long-term care facility administrators and government overseers to identify potential problems in patient care.

Quality of life: An individual's sense of well-being and ability to carry out activities of daily living.

Quiescence: Dormant disease.

Radon: A chemically inert, radioactive gaseous element produced by the decay of radium, which is a risk factor for developing lung cancer.

Rapid cycling: Four or more mood episodes (major depressive, manic, or hypomanic) within 1 year.

Rapid eye movement sleep: Phase of sleep in which the eyes move rapidly, there is low muscle tone, and dreaming may occur.

Rapid sequence intubation: An airway procedure that aims to reduce the incidence of complications when placing an endotracheal tube. During the procedure, agents are utilized to induce an amnestic state while also causing muscle relaxation to allow for easier passage of the tube to the lungs.

Raynaud Disease: Decrease in blood flow to fingers or toes due to spasming of blood vessels; occurs in response to cold temperatures or stress; results in numbness, pain, and color changes of affected digits.

Rectal prolapse: Externally visible sinking of the rectum through the anal sphincter.

Recurrence: The development of a new episode after a patient has achieved remission of a condition or disease for a sustained period of time.

Reentry: Circular movement of electrical impulses, a mechanism of many arrhythmias.

Regurgitation: The effortless and nonprojectile passage of refluxed gastric contents into the pharynx or mouth.

Relapse: Return of symptoms prior to achieving remission or shortly after achieving remission. The relapse is typically considered a return of the original symptoms rather than a new episode as in recurrence.

Remission: A near absence of symptoms or return to baseline between episodes. Patient has no or minimal symptoms of disease. In the case of cancer in partial remission, some but not all signs and symptoms of cancer have disappeared. In complete remission, all signs and symptoms of cancer have disappeared, although cancer still may be in the body.

Renin–angiotensin–aldosterone system: The hormonal system controlled mainly by the kidneys and adrenal glands, which regulates blood pressure, blood volume, and electrolyte balance.

Resistance-associated substitution: Resistance to a drug resulting in decreased antiviral activity caused by an amino acid change in the viral protein.

Resistant: A disease state or medical condition, such as cancer or infection, that does not respond to treatment.

Respiratory disturbance index: Measure reported on polysomnography that reports respiratory events during sleep.

Response inhibition: Ability to stay on task.

Reticulocytes: Immature blood cells that mature into erythrocytes.

Retinopathy: Occurs when the microvasculature nerve layer that provides blood and nutrients to the retina is damaged and can cause blindness.

Retrograde ejaculation: Semen flows to the bladder instead of the urethra.

Retrograde pyelography: Injection of a radiocontrast agent into the ureters to visualize the ureter and kidney with fluoroscopy or radiography.

Retrovirus: An RNA virus that uses an enzyme, reverse transcriptase, to turn the RNA into DNA in order to become part of the host cell's DNA (eg, Human Immunodeficiency Virus).

Rhabdomyolysis: Muscle symptoms with marked elevation in creatine kinase at 40 times the upper limit of normal which results in myoglobinuria and acute renal failure.

Rheumatic fever: A rare, acute immune-mediated disease that occurs mainly in children and young adults that is characterized by fever, arthritis, and inflammation of the pericardium and heart valves; it is associated with untreated or undertreated group A streptococcal disease.

Rheumatic heart disease: Valvular heart disease resulting from acute rheumatic fever.

Rheumatoid factors: Antibodies reactive with the Fc region of IgG.

Rhonchi: Abnormal, rumbling sounds heard on auscultation of an obstructed airway; more prominent during expiration and may clear somewhat on coughing.

Rickettsia: Intracellular bacteria often associated with tick bites and causing a nonspecific febrile syndrome.

Rotational thromboelastometry: A type of viscoelastic testing that measures clot formation to breakdown.

Rubefacient: A substance that produces redness of the skin.

Salicylism: A toxic syndrome caused by excessive doses of acetylsalicylic acid (aspirin), salicylic acid, or any other salicylate product. Signs and symptoms may include severe headache, nausea, vomiting, tinnitus (ringing in the ears), confusion, increased pulse, and increased respiratory rate.

Salmonella: Gram-negative enteric rod known to cause gastroenteritis.

Scleritis: Inflammation of the outer layer of the eyeball (sclera).

Scoliosis: Abnormal lateral (sideways) curvature of the spine.

Scotoma: A spot in the visual field in which vision is absent or deficient.

Sebaceous gland: Gland that produces sebum.

Sebum: Substance produced by the sebaceous gland that is composed of lipids.

Secondary amenorrhea: Absence of menses for three cycles or 6 months in a previously menstruating woman.

Seizure: A sudden electrical disturbance of the cerebral cortex, when a population of neurons fires rapidly and repetitively for seconds to minutes and electrical discharges are excessively rapid, rhythmic, and synchronous.

Sensitive: A disease state or medical condition that responds to treatment.

Sentinel lymph node: The first lymph node to which cancer is likely to spread from the primary tumor.

Sequential compression devices: A nonpharmacologic method of preventing venous thromboembolism.

Seropositive: Showing a positive reaction to a test on blood serum for a disease.

Severe myoclonic epilepsy of infancy: See Dravet syndrome.

Shigella: Gram-negative enteric bacteria causing a syndrome of explosive infectious diarrhea.

Sialorrhea: Drooling.

Sigmoidoscopy: Visual inspection of the sigmoid colon and rectum with a flexible tube called a sigmoidoscope.

Sleep apnea: Temporary stoppage of breathing during sleep; can be caused by narrowing of the airways resulting from swelling of soft tissue.

Sleep latency: Amount of time it takes to fall asleep.

Sleeve gastrectomy: A surgical treatment for weight loss that involves constructing a small gastric "sleeve" but cutting vertically and removing up to 90% of the stomach.

Slit-lamp biomicroscope: An instrument that allows for the microscopic examination of the cornea, anterior-chamber lens, and posterior chamber.

Spasticity: Feelings of stiffness and involuntary muscle contractions or sudden movements.

Sphincter of Oddi: Muscle where common bile duct empties into small intestine.

Spirometry: Measurement by means of a spirometer of the air entering and leaving the lungs.

Splanchnic: Relating to the viscera or internal organs.

Spondylolysis: A stress fracture in the lumbar spine through the pars interarticularis, a thin bone joining two vertebrae.

Stable disease: Cancer that has either insufficient increase to be defined as progressive disease or shrinkage to be defined as a response.

Steatohepatitis: A severe form of liver disease caused by fat deposition in the liver, characterized by hepatic inflammation that may rapidly progress to liver fibrosis and cirrhosis.

Steatorrhea: Passage of fat in large amounts in the feces, due to the failure to digest and absorb it.

Steatosis: Infiltration of liver cells with fat.

Stenting: Placement of a stent (a metal or plastic tube) to allow blood flow through an artery.

Stent retriever: Thrombectomy device used to trap a thrombus between the arterial wall and stent to allow rapid restoration of blood flow. The stent is pulled back to remove the thrombus.

Stevens-Johnson syndrome: A severe expression of erythema multiforme (also known as erythema multiforme major); typically involves the skin and the mucous membranes, with the potential for severe morbidity and even death.

Stimulant: Medication that increases functional activity in the body.

Stomatitis: Inflammation of mucous membranes in the mouth.

Stricture: An abnormal narrowing of a body passage, especially a tube or a canal.

Stridor: High-pitched, whistling sound.

Stroke volume: The amount of blood ejected from the heart during systole.

Strongyloides: Parasitic nematode generally causing gastrointestinal syndromes, although it does have the ability to cause disseminated disease.

ST-segment elevation myocardial infarction: A type of myocardial infarction that typically results in an injury that transects the thickness of the myocardial wall.

Subchondral: Situated beneath and supporting cartilage.

Substance use disorder: Recurrent use of a substance and the pathological pattern of behaviors that result from substance use, including significant impairment in health, disability, or failure to meet obligations at home, work, or school.

Substantia nigra: The area in the brainstem with highly pigmented cells that make dopamine.

Suspending agent: An additive used in the compounding of oral liquid medications to suspend drug particles throughout a liquid and enables resuspension of particles by agitation (e.g., shaking well).

Swan neck deformity: Joint deformity associated with rheumatoid arthritis that presents as flexion of the distal interphalangeal (DIP) joints with hyperextension of the proximal interphalangeal (PIP) joints.

Sympathomimetic: An agent that mimics the activity of a naturally occurring agonist, like epinephrine, to activate the sympathetic nervous system. Examples include ephedrine, pseudoephedrine, and phenylephrine.

Synechia: Adhesions or abnormal attachment of the iris to another structure. Peripheral anterior synechia refers to occurrence of synechia with the trabecular meshwork.

Synovitis: Inflammation of the synovial membrane, often in combination with pain and swelling of the affected joint.

Synovium: The membrane lining the internal surfaces of joints.

Systemic inflammatory response syndrome: A complex pathophysiologic response to an insult such as infection, trauma, burns, pancreatitis, and/or other injuries.

T-lymphocyte: A type of white blood cell that originates in the bone marrow and matures in the thymus and serves an essential role in the adaptive immune system.

T2-weighted magnetic resonance imaging: A setting of the magnetic resonance imaging machine that shows water and similar fluids such as cerebrospinal fluid as a bright signal.

Tachycardia: An abnormally rapid heart rate.

Tachyphylaxis: The continued or repeated exposure to a drug that may lead to a diminished pharmacological response over time.

Tachypnea: Faster than normal respiratory rate.

Tachypneic: Rapid breathing indicated by a rate of greater than 20 breaths/min.

Tangentiality: Abandoning one's ideational objective in pursuit of thoughts peripheral to the original goal. Used to describe a thought and speech pattern wherein the individual never gets to the point or answers the question.

Tardive dyskinesia: A chronic disorder of the nervous system characterized by involuntary jerky or writing movements of the face, tongue, jaws, trunk, and limbs, usually developing as a late side effect of prolonged treatment with antipsychotic drugs.

Targeted therapy: A type of treatment that uses drugs or other substances to identify and attack specific types of cancer cells with less harm to normal cells.

Tendinosis: Tendon degeneration without accompanying inflammation.

Tenesmus: Difficulty with bowel evacuation despite the urgency to defecate.

Teratogenic: Causing malformation in a fetus.

Terminal secretions: The noise produced by the oscillatory movements of secretions in the upper airways in association with the inspiratory and expiratory phases of respiration. It is also known as "death rattle."

Tetany: A condition characterized by spasms of the hands and feet, cramps, spasm of the voice box (larynx), and overactive neurological reflexes usually due to low blood calcium.

Thelarche: Onset of breast development.

Thought blocking: Speech is halted, often in midsentence, and then picked up later, usually at another point in the thought process.

Thrombin: An enzyme formed from prothrombin which converts fibrinogen to fibrin and also activates platelets. It is the principal driving force in the clotting cascade.

Thrombocytopenia: A condition whereby the number of circulating platelets are abnormally low due to decreased production of new cells, possibly secondary to medication toxicities.

Thrombocytosis: Increased number of platelets in the blood.

Thromboelastography: A type of viscoelastic testing that measures clot formation to breakdown.

Thrombogenesis: Process of forming a blood clot.

Thrombolysis: Process of enzymatically dissolving or breaking apart a blood clot.

Thrombolytic: An enzyme that dissolves or breaks apart blood clots.

Thrombophlebitis: Inflammation of a blood vessel (eg, vein) associated with the stimulations of clotting and formation of a thrombus (or blood clot).

Thromboplastin: A substance that triggers the coagulation cascade. Tissue factor is a naturally occurring thromboplastin and is used in the prothrombin time test.

Thrombosis: A condition in which blood changes from a liquid to a solid state and produces a blood clot.

Thrombotic thrombocytopenic purpura: Condition characterized by formation of small clots within the circulation resulting in the consumption of platelets and a low platelet count.

Thrombus: Blood clot attached to the vessel wall and consisting of platelets, fibrin, and clotting factors; may partially or completely occlude the lumen of a blood vessel compromising blood flow and oxygen delivery to distal tissue.

Thyroglobulin: A thyroid hormone-containing protein, usually stored in the colloid within thyroid follicles.

Thyroid peroxidase: Enzyme that catalyzes the organification and coupling steps of thyroid hormone synthesis.

Thyroiditis: Inflammation of the thyroid gland.

Thyrotoxicosis: A syndrome caused by elevated levels of thyroid hormone; often caused by hyperthyroidism, a condition in which the thyroid gland produces excessive levels of thyroid hormone.

Tocolytic: Medication used to stop premature labor.

Tonometry: Method by which the cornea is indented or flattened to measure intraocular pressure.

Tophi: Collections of monosodium urate crystals that develop in tissues and generally appear as firm nodules under the skin.

Topoisomerase-I: Enzymes that cut one of the two strands of double-stranded DNA, relax the strand, and reanneal the strand.

Torsade de pointes: Very rapid ventricular tachycardia characterized by a gradually changing QRS complex in the electrocardiogram; may change into ventricular fibrillation.

Total abdominal hysterectomy and bilateral salpingo-oophorectomy: Surgical removal of the uterus, fallopian tubes, and ovaries which results in immediate menopause.

Total fertility rate: The average number of children a woman would have if she survives all her childbearing (or reproductive) years, which are typically considered to be between 15 and 49.

Toxic epidermal necrolysis: A life-threatening skin disorder characterized by blistering and peeling of the top layer of skin.

Transcranial magnetic stimulation (TMS): A form of neurostimulation therapy that involves the use of a magnet placed over the head. TMS is thought to induce the release of monoamine neurotransmitters.

Transesophageal echocardiogram: Procedure used to generate an image of the heart via sound waves, via a probe introduced into the esophagus (rather than the traditional transthoracic view) in order to obtain a better image of the left atrium.

Transferrin saturation: The ratio of serum iron and total iron-binding capacity, multiplied by 100.

Transformation/conversion: The change that a normal cell undergoes to become malignant.

Transmural: Existing or occurring across the entire wall of an organ or blood vessel.

Transsphenoidal pituitary microsurgery: Surgery through the nasal cavity to access the pituitary gland through the sphenoid bone.

Traveler's diarrhea: An acute infectious diarrhea that afflicts travelers during or immediately upon return and is due to ingestion of contaminated food or beverages resulting in diarrhea and other gastrointestinal symptoms.

Trigeminal neuralgia: Sudden, severe facial pain described as sharp shooting pain or electric shock in the jaw, teeth or gums.

Triple-negative breast cancer: Characterized by the absence of the three receptors used to guide treatment; this subtype is associated with the poorest prognosis.

Trismus: Limited jaw range of motion (also known as "lockjaw").

Trophic feeding: Very low-rate feedings designed to keep the gut stimulated.

Troponins T or I: Proteins found predominately in the myocardium. Troponin I and T are released into the blood from the myocytes at the time of myocardial cell necrosis secondary to infarction. These biochemical markers become elevated and are used in the diagnosis of myocardial infarction.

Trousseau's sign: Elicited by inflating a blood pressure cuff on the patient's upper arm, whereby hypocalcemic patients will experience tetany of the wrist and hand as evidenced by thumb adduction, wrist flexion, and metacarpophalangeal joint flexion.

Trypsin: A proteolytic enzyme formed in the small intestine from trypsinogen by the action of enteropeptidase, which once activated hydrolyzes peptides, amides, and esters.

Tuberoeruptive xanthomas: Small yellow-red raised papules usually presenting on the elbows, knees, back, and buttocks.

Tuberoinfundibular: One of the four main dopamine pathways in the brain, projecting from the arcuate and periventricular nuclei of the hypothalamus to the infundibular region of the hypothalamus.

Tubulointerstitial: Involving the tubules or interstitial tissue of the kidneys.

Tumor lysis syndrome: A syndrome resulting from cytotoxic therapy, occurring generally in aggressive, rapidly proliferating lymphoproliferative disorders; characterized by combinations of hyperuricemia, lactic acidosis, hyperkalemia, hyperphosphatemia, and hypocalcemia.

Tumor suppressor gene: A gene that suppresses growth of cancer cells.

Tympanocentesis: Puncture of the tympanic membrane with a needle to aspirate middle ear fluid.

Tympanostomy tube: Small plastic or metal tube surgically inserted in the eardrum to keep the middle ear aerated and improve hearing in patients with chronic middle ear effusion.

Uhthoff phenomenon: Acute worsening of multiple sclerosis symptoms on exposure to heat because high body temperatures may exceed the capacitance of the demyelinated nerve and conduction may fail.

Unknown-onset seizures: Seizures where the onset (ie, focal or generalized) cannot be determined.

Unstable angina: Pathogenically similar to non–ST-segment myocardial infarction but without muscle damage, therefore troponins are not elevated.

Uremia: A condition that results from accumulation of metabolic waste products and endogenous toxins in the body resulting from impaired kidney function; symptoms include nausea, vomiting, weakness, loss of appetite and mental confusion.

Urethral stricture: Narrowing of the urethra.

Urgency (urinary): A compelling need to urinate that is difficult to defer.

Uricosuric: Pertaining to, characterized by, or promoting renal excretion of uric acid.

Urticaria: Itchy, raised, swollen areas on the skin, also known as hives.

Uterine tachysystole: Uterine hyperstimulation with frequent contractions, hypertonus and non-reassuring fetal heart rate pattern.

Uveitis: Inflammation of the uvea. Uveal structures include the iris, the ciliary body, and the choroid.

Valsalva maneuver: A technique that forces respiratory expiration against a closed glottis.

Valvular heart disease: Damage or defects in one or more of the heart valves, disrupting blood flow into and out of the heart. The most common valves affected are the aortic and mitral valves. Valvular stenosis is a narrowing of the valve opening restricting the forward flow of blood. Valvular regurgitation or insufficiency occurs when there is inadequate closure of the valve leaflets leading to blood "leaking" backward.

Vasculitis: Inflammation of the walls of blood vessels.

Vasomotor symptoms: Menopausal symptoms that include both hot flashes (flushes) and night sweats for which women most commonly seek therapy.

Vasopressors: Medications that cause constriction of blood vessels, increase in vascular resistance, and increase in blood pressure.

Ventilation: Movement of air between the environment and the lungs.

Ventilation/perfusion ratio (V_A/Q): A comparison of the proportion of lung tissue being ventilated by inhaled air to the rate of oxygenation of pulmonary blood.

Ventricular depolarization: Change in the membrane potential of a ventricular myocyte, resulting in loss of polarization. Under normal conditions, depolarization of ventricular myocytes is followed by ventricular contraction.

Vertigo: Sensation of spinning or feeling out of balance.

Vesicants: Chemotherapy drugs that cause significant tissue damage if extravasation occurs.

Viral hemorrhagic fevers: Highly virulent viral diseases causing significant hematologic abnormalities and a high mortality rate. Ebola would be the most well-known.

Virilization: Production or acquisition of virilism, which is masculine characteristics.

Viscoelastic testing: Point-of-care testing devices utilizing thromboelastography principles to evaluate clot formation and dissolution.

Volvulus: Twisting of the intestine causing obstruction and possible necrosis.

Vulvovaginal atrophy: Thinning of vaginal tissue due to a lack of estrogen stimulation.

Wernicke syndrome: Neurologic condition caused by thiamine deficiency and characterized by mental confusion, ataxia, and ophthalmoplegia.

West Nile encephalitis: Mosquito-borne disease causing a clinical syndrome of viral encephalitis.

Wheeze: A high-pitched whistling sound caused by air moving through narrowed airways; usually heard at the end of expiration but may be heard during inspiration and expiration in acute severe asthma.

White coat hypertension: A persistently elevated average office blood pressure of greater than 140/90 mm Hg and an average awake ambulatory reading of less than 135/85 mm Hg.

Wilson Disease: A disorder of copper metabolism, characterized by cirrhosis of the liver and neurological manifestations.

Xanthomas: Firm raised nodules composed of lipid-containing histocytes.

Xerostomia: Unusual dryness of the mouth.

ZAP-70 expression: An intracellular tyrosine kinase found in CLL B-cells.

Zika virus: Mosquito-borne disease associated with fetal neurologic developmental anomalies when acquired by pregnant women.

Zymogen: An inactive protein precursor of an enzyme that is converted into an active form.

Alpelisib, for cancer, 1400t, 1411, 1415t
α_1-Adrenergic antagonists. *See also specific drugs*
  adverse effects of, 854, 857t
  for benign prostatic hypertrophy, 851–852, 852t, 853t, 854, 856, 857t, 858
α_1-Antitrypsin augmentation therapy, for chronic obstructive pulmonary disease, 318
α_1-Antitrypsin deficiency (AATD), cirrhosis and, 402
α_1-Blockers. *See also specific drugs*
  for hypertension, 96t, 99
α_2-Agonists. *See also specific drugs*
  central, for hypertension, 95t, 99–100
α-Adrenergic agonists. *See also specific drugs*
  for glaucoma, 1008t, 1012
  for stress urinary incontinence, 870, 871t
α-Glucosidase inhibitors, for diabetes mellitus, 711t, 716t, 717
Alprazolam
  for generalized anxiety disorder, 671t
  for nausea and vomiting, 377t
Alprostadil, for erectile dysfunction, 841t, 843–844, 844f
ALS. *See* Amyotrophic lateral sclerosis
Alteplase
  for acute coronary syndromes, 170t
  for ischemic stroke treatment, 253t
  for stroke prevention, 248–249, 249t
  for venous thromboembolism treatment, 223t
Altretamine, for ovarian cancer, 1512t
Aluminum toxicity, as parenteral nutrition complication, 1625
Alzheimer disease (AD)
  clinical presentation and diagnosis of, 504–506, 505t
  epidemiology and etiology of, 503
  genomics of, 510
  outcome evaluation for, 510
  palliative care for, 29
  pathophysiology of, 504
  patient care process for, 510
  patient encounters, 505, 509–510
  treatment of
    for behavioral symptoms, 509
    conventional pharmacologic, 506–508, 506t, 507t, 508t
    desired outcomes for, 506
    general approach to, 506
    nonconventional pharmacologic, 508–509
    nonpharmacologic, 506, 506t
Amantadine
  for multiple sclerosis, 524t
  for Parkinson disease, 563t, 565–566
Ambulation, impaired, treatment of, 524–525
Ambulatory clinics, geriatric, 11
Ambulatory esophageal reflux monitoring, in gastroesophageal reflux disease, 338
Amcinonide, topical, for psoriasis, 1092t
Amenorrhea
  in adolescents, 822
  clinical presentation and diagnosis of, 823
  epidemiology and etiology of, 821
  expected outcome measures for, 822t
  pathophysiology of, 821, 821f
  primary, 821
  with progestin-only contraceptives, 810
  secondary, 821
  treatment of, 819t–820t, 821–822, 823f
Amifostine, for mucositis, 1585
Amikacin
  for cystic fibrosis, 330t, 331, 331t
  for pneumonia, 1194t, 1195t
  for urinary tract infections, 1292t
Amikacin/kanamycin, for tuberculosis, 1262t
Amiloride, for hypertension, 94t
Amino acids, in parenteral nutrition admixtures, 1612–1613
Aminoglycosides
  acute kidney injury with, 446
  adverse drug reactions of, 1157t, 1158t
  for gonorrhea, 1301
  for pneumonia, 1190t
  pregnancy changes to pharmacokinetics of, 790t
  for urinary tract infections, 1292t, 1293, 1295t
Aminolevulinic acid (ALA), for keratinocyte carcinoma, 1497, 1498t

Aminosalicylates, for inflammatory bowel disease, 360–361, 361*t*, 365, 368
Amiodarone
  adverse effects of, 195*t*
  for atrial fibrillation, 194*t*, 196*t*, 198*t*
  lactation and, 791*t*
  teratogenicity of, 788*t*
  thyroid disorders induced by, 745
  for ventricular fibrillation, 206*t*
  for ventricular tachycardia, 204*t*
Amitriptyline
  for irritable bowel syndrome, 397*t*
  for major depressive disorder, 640*t*
  for migraine prophylaxis, 590*t*, 591
  for pain, 581*t*
AML. *See* Acute myelogenous leukemia
Amlodipine
  adverse effects of, 181*t*
  for hypertension, 95*t*
  for ischemic heart disease, 149, 150*t*
Ammonia water, for musculoskeletal disorders, 997*t*
Amoxicillin
  for acute bacterial rhinosinusitis, 1205–1206, 1206*f*, 1207*t*
  for chlamydia infection, 799*t*, 1304, 1305*t*
  for *Helicobacter pylori*-associated ulcers, 351*t*
  for infective endocarditis, 1251*t*
  for otitis media, 1201–1202, 1201*f*, 1202*t*
  for pharyngitis, 1208, 1209*t*
  for pneumonia, 1190*t*, 1193*t*
  for preterm premature rupture of membranes, 792, 794*t*
  for urinary tract infections, 793*t*, 1292*t*
Amoxicillin/clavulanate
  for acute bacterial rhinosinusitis, 1205–1206, 1206*f*, 1207*t*
  for cellulitis, 1221*t*
  for cystic fibrosis, 330*t*
  for diabetic foot infections, 1225*t*
  for mastitis, 795*t*
  for otitis media, 1201–1202, 1201*f*, 1202*t*
  for pneumonia, 1190*t*, 1193*t*
  for urinary tract infections, 1292*t*, 1293*t*
Amphetamines. *See also specific drugs*
  for attention-deficit/hyperactivity disorder, 695, 696*t*, 697*t*
  drug interactions of, 600*t*
  intoxication by, 599*t*, 601
  withdrawal from, 599*t*, 603
Amphotericin B
  acute kidney injury with, 446–447
  adverse drug reactions of, 1157*t*
  for aspergillosis, 1354*t*, 1358–1359
  for CNS infections, 1175*t*
  for cryptococcosis, 1354*t*, 1356
  for endemic fungal infections, 1348*t*, 1349–1351
  for invasive candidiasis, 1353, 1354*t*
  liposomal, for febrile neutropenia prevention, 1591*t*
  for oropharyngeal and esophageal candidiasis, 1338–1339
Amphotericin B deoxycholate, for febrile neutropenia prevention, 1591*t*
Ampicillin
  for CNS infections, 1172*t*, 1173*t*, 1177*t*
  for group B *Streptococcus* infection, in pregnancy, 794*t*
  for infective endocarditis, 1247*t*, 1250*t*, 1251*t*
  for intra-abdominal infections, 1286*t*
  for osteomyelitis, 1232*t*
  for pneumonia, 1190*t*
  for preterm premature rupture of membranes, 792, 794*t*
  for urinary tract infections, 793*t*, 1292*t*, 1293
Ampicillin/sulbactam
  for cellulitis, 1221*t*
  for diabetic foot infections, 1225*t*
  for infective endocarditis, 1250*t*
  for pelvic inflammatory disease, 1317*t*
  for pneumonia, 1190*t*
  for urinary tract infections, 1292*t*
Amprenavir, 1382*t*
AMR. *See* Antibody-mediated rejection
Amrinone, for heart failure, 129
Amyotrophic lateral sclerosis (ALS), palliative care for, 29
ANA. *See* Antinuclear antibodies
Anaerobes, intra-abdominal infections due to, 1280, 1285
Anakinra
  for gout, 983, 983*t*
  for rheumatoid arthritis, 959
Analgesics. *See also specific drugs and drug types*
  for acute pancreatitis, 416
  for chronic pancreatitis, 418
  for common cold, 1212*t*
  for headache, 588–590, 589*t*
  for musculoskeletal disorders, 995–997, 997*t*
  for pain
    combination, 579
    nonopioid, 576–577
    opioid, 577–580, 577*t*, 578*t*, 579*t*, 580*t*
  for sepsis and septic shock, 1328
  for sore throat, 1043*t*
Anaphylactoid reactions, 882–884
Anaphylaxis, drug-induced, 882–886, 884*t*
Anaplastic lymphoma kinase (ALK) inhibitors, 1400*t*, 1409
Anastomosis, 891
Anastrozole, 1415*t*
  for cancer, 1399*t*, 1412, 1427, 1428*t*
Androgen deprivation therapy (ADT), for prostate cancer, 1473, 1477–1478, 1480
Androgen receptor antagonist, for cancer, 1399*t*
Androgen synthesis inhibitors, for prostate cancer, 1479*t*, 1481
Androgens. *See also specific androgens*
  for breast cancer, 1430
  teratogenicity of, 788*t*
Androstenedione, 749, 750*f*
Anemia
  of chronic kidney disease
    epidemiology and etiology of, 458–459
    nonpharmacologic treatment of for, 459
    outcome evaluation for, 462–463
    pathophysiology of, 459
    pharmacologic therapy for, 459–462, 460*f*, 461*t*, 462*t*
    treatment of, 1112
  clinical presentation and diagnosis of, 1105–1106
  in cystic fibrosis, 328
  epidemiology and etiology of, 1103, 1103*t*
  outcome evaluation for, 1113
  pathophysiology of, 1103–1104, 1104*f*, 1105*f*, 1106*f*
  patient care process for, 1113
  patient encounters, 1107, 1109, 1110, 1111, 1112
  in pregnancy, 791–792, 793*t*
  reduction in risk of, with combination oral contraceptives, 807
  treatment of
    for anemia of chronic disease, 1110–1113, 1111*t*
    desired outcomes for, 1104
    general approach to, 1104, 1107*f*, 1108*t*
    for iron-deficiency anemia, 1106, 1108–1110, 1109*t*, 1110*t*
    nonpharmacologic, 1106, 1108*t*
    for vitamin B12 and folic acid anemia, 1110
Anergy, T-cell, 893
Anesthetics
  for aphthous stomatitis, 1038
  for musculoskeletal disorders, 996
Aneurysms, cerebral, 243
Angina. *See also* Acute coronary syndromes
  conditions associated with, 135, 137*f*, 138*t*
  hypertension and, treatment of, 100–101
  microvascular, treatment of, 152
  unstable, 157
  variant, treatment of, 152
Angioedema, drug-induced, 884–885
Angiotensin II
  for acute coronary syndrome prevention, 147
  heart failure and, 110
  for sepsis and septic shock, 1327
Angiotensin receptor blockers (ARBs). *See also specific drugs*
  for acute coronary syndrome, prevention of, 145, 147, 147*t*
  for acute coronary syndromes, 171*t*, 179

  acute kidney injury with, 447–448
  adverse effects of, 118*t*, 181*t*
  for heart failure, 116*t*, 120
  for hypertension, 95*t*, 98–99
  teratogenicity of, 788*t*
Angiotensin receptor neprilysin inhibitor (ARNI), for heart failure, 116*t*
Angiotensin-converting enzyme (ACE) inhibitors. *See also specific drugs*
  for acute coronary syndrome, prevention of, 145, 147, 147*t*
  for acute coronary syndromes, 171*t*, 178, 179
  acute kidney injury with, 447–448
  adverse effects of, 118*t*, 181*t*
  for heart failure, 116*t*, 119–120
  for hypertension, 95*t*, 98, 102*t*
  teratogenicity of, 788*t*
Anidulafungin
  for febrile neutropenia prevention, 1591*t*
  for invasive candidiasis, 1353
Animal bites, 1225–1226, 1226*t*
Anion gap, 497
Anosmia, in Parkinson disease, 559
Anovulatory bleeding
  in adolescents, 824
  clinical presentation and diagnosis of, 824
  epidemiology and etiology of, 822
  expected outcome measures for, 822*t*
  pathophysiology of, 823
  treatment of, 819*t*–820*t*, 823–824
Anovulatory cycles, 827
Antacids, for gastroesophageal reflux disease, 339*t*, 341–342
Anterograde amnesia, benzodiazepines and, 669
Anthracene derivatives, for cancer, 1399*t*, 1403
Anthracyclines, toxicity of, 1426*t*
Anthralin, for psoriasis, 1093*t*
Antiandrogens, for cancer, 147*t*, 1399*t*, 1412, 1477, 1479*t*, 1480–1481. *See also specific drugs*
Antiarrhythmic drugs, Vaughan Williams classification of, 188, 189*t*. *See also specific drugs*
Antibiotic stewardship. *See* Antimicrobial stewardship
Antibiotics. *See also specific drugs*
  for acne, 1067, 1069, 1070*t*–1071*t*
  for acute pancreatitis, 416, 416*t*
  allergies to, 883–884, 884*t*, 885*t*
  antitumor, 1399*t*
  β-lactam. *See* β-Lactam antibiotics
  for bite wound infections, 1226
  for cellulitis, 1218–1222, 1221*t*
  for chronic obstructive pulmonary disease exacerbations, 319, 319*t*
  for cystic fibrosis, 330–332, 330*t*, 331*t*
  for diabetic foot infections, 1225, 1225*t*
  for diaper dermatitis, 1083, 1084*f*
  for gastrointestinal infections, 1269–1272
  for hepatic encephalopathy, 410
  for impetigo, 1218
  for inflammatory bowel disease, 363

  for sepsis, 1324–1326
  for tuberculosis, 1259–1264, 1260*t*, 1261*t*, 1262*t*–1263*t*
  for urinary tract infections, 1291–1294, 1292*t*, 1293*t*, 1295*t*
Antimotility agents, 392, 397*t*
Antimuscarinics. *See also specific drugs*
  adverse effects of, 868, 870*t*
  for allergic rhinitis, 1057
  for chronic obstructive pulmonary disease, 315, 316*t*–317*t*
  for nonallergic rhinitis, 1030*t*
  for urge urinary incontinence, 868, 869*t*
Antineoplastics, lactation and, 791*t*
Antinuclear antibodies (ANA), 915–916, 916*f*
Antioxidants, ischemic heart disease and, 151
Antiperistaltic agents, for diarrhea, 392
Antiphospholipid syndrome (APS), 930
Antiplatelet agents. *See also specific drugs*
  for acute coronary syndrome, 166, 167*t*
    prevention of, 145, 146*t*
  for heart failure, 123
  for stroke prevention, 250–252
Antiproliferative drugs, for organ transplantation, 895*t*, 898, 900
Antipsychotics. *See also specific drugs*
  for Alzheimer disease, 509
  first-generation (typical)
    for bipolar disorder, 654–656, 660
    for schizophrenia, 615, 618–621, 619*t*, 620*t*–621*t*
    side-effects of, 615, 619, 621, 621*t*
  pharmacokinetics and drug interactions of, 626–627, 627*t*
  for schizophrenia, 615–628, 616*t*, 617*t*, 619*t*, 620*t*–621*t*, 623*t*–624*t*, 625*t*, 627*t*
  second-generation (atypical)
    for bipolar disorder, 654–656, 658*t*, 660
    for generalized anxiety disorder, 670–671, 670*t*
    for posttraumatic stress disorder, 678
    for schizophrenia, 615–618, 616*t*, 617*t*
    side-effects of, 615, 617*t*
Antipyretics, for common cold, 1212*t*
Antireflux surgery, 339, 340*t*, 341
Antiretroviral therapy (ART). *See also specific drugs*
  adverse effects of, 1382*t*–1383*t*, 1384*t*–1385*t*
  for antiretroviral-experienced patients, 1369, 1378–1379, 1378*t*
  for antiretroviral-naïve patients, 1368–1369, 1368*t*, 1369*t*, 1370*t*–1373*t*, 1374*t*–1377*t*
  combination, 1365–1367, 1367*t*, 1368*t*, 1369*t*, 1374*t*–1377*t*, 1378–1379
  HIV life cycle and, 1364–1365, 1364*f*
  for pre-exposure prophylaxis, 1381
  pregnancy changes to pharmacokinetics of, 790*t*
  resistance to, 1368–1369, 1378–1379
  in special populations, 1379–1380
Anti-Rh(D), for immune thrombocytopenia, 1128–1129
Antisclerostin antibody, for osteoporosis, 944*t*, 946
Antisecretory agents, for diarrhea, 392–393
Antisense oligonucleotides
  for dyslipidemia, 275
  formulations, dosing and adverse effects of, 272*t*
Antispasmodics. *See also specific drugs*
  for hemorrhagic cystitis, 1599
  for irritable bowel syndrome, 396, 397*t*
Antithymocyte globulin (ATG), for graft-versus-host disease, 1572
Antithymocyte globulin equine, for organ transplantation, 895*t*, 896
Antithymocyte globulin rabbit, for organ transplantation, 895*t*, 896, 902
Antithyroid drugs, 742
Antitumor antibiotics, 1399*t*
Antitussives, for cough, 1040*t*

Antivirals. *See also* Antimicrobials; *specific drugs*
  for cold sores, 1035*t*
  for cytomegalovirus prophylaxis, 905*t*, 906
  for genital herpes, 1315–1316, 1315*t*
Anxiety
  in critical care medicine, 42–43
  palliative care for, 30
Anxiety disorders
  clinical presentation and diagnosis of, 667, 667*t*, 668*t*, 671, 674, 676

    general approach to, 849–851, 850*f*, 851*t*, 852*t*
    mirabegron for, 852*t*, 856, 857*t*, 858
    nonpharmacologic therapy for, 851
    5α-reductase inhibitor therapy for, 852*t*, 854–856, 855*t*, 857*t*, 858
    tadalafil for, 852*t*, 856, 857*t*, 858
Benralizumab, for asthma, 299, 300*t*
Benzamides, for nausea and vomiting, 376*t*
Benzathine penicillin G, for syphilis, 799*t*, 1307*f*, 1308, 1308*t*, 1309*t*, 1310*f*
Benzocaine, for sore throat, 1043*t*
Benzodiazepines
  for alcohol withdrawal, 601–602
  comparison of, 671*t*
  for generalized anxiety disorder, 669, 671*t*
  for insomnia, 684, 686, 686*t*
  for nausea and vomiting, 377*t*, 378
  for panic disorder, 673
  for parasomnias, 688
  for social anxiety disorder, 675
  for status epilepticus, 549–550, 551*t*, 552, 552*t*, 553*t*
Benzonatate, for cough, 1040*t*
Benzoyl peroxide, for acne, 1067, 1068*t*
Benztropine
  for Parkinson disease, 563*t*
  for schizophrenia, 627
Bepotastine, for allergic rhinitis, 1059*t*
Bet, adverse effects of, 118*t*
Betamethasone
  pharmacologic characteristics of, 754*t*
  in pregnancy, 793*t*
  topical, for psoriasis, 1092*t*
Betamethasone dipropionate, topical, for psoriasis, 1092*t*
Betamethasone valerate, topical, for psoriasis, 1092*t*
Betaxolol
  for ischemic heart disease, 149*t*
  for primary open-angle glaucoma, 1008*t*
β-Agonists. *See also specific drugs*
  for anaphylactic reactions, 884*t*
  for chronic obstructive pulmonary disease, 315, 316*t*–317*t*
β-Blockers. *See also specific drugs*
  for acute coronary syndromes, 170*t*, 177–178, 179
    prevention of, 145
  adverse effects of, 118*t*, 149, 181*t*
  for asthma, 296, 297*t*, 298, 298*t*
  for atrial fibrillation, 194*t*
  for chronic obstructive pulmonary disease, 315, 316*t*–317*t*, 318
  for glaucoma, 1008*t*, 1011–1012
  for heart failure, 116*t*, 121
  for hypertension, 94*t*, 97–98, 98*f*
  for hyperthyroidism, 741, 744
  for ischemic heart disease, 148–149, 148*t*, 149*t*
  lactation and, 791*t*
  long-acting
    for asthma, 296, 298, 298*t*, 300*t*
    for chronic obstructive pulmonary disease, 315, 316*t*–317*t*
  for migraine prophylaxis, 590–591, 590*t*
  nonselective, for portal hypertension, 408
  after organ transplantation, 908
  for paroxysmal supraventricular tachycardia, 202*t*
  for premature ventricular complexes, 203
  short-acting
    for asthma, 296, 299–300
    for chronic obstructive pulmonary disease, 315, 316*t*–317*t*
  for social anxiety disorder, 675
  for ventricular tachycardia, 204*t*
β-Interferons, for multiple sclerosis, 517, 518*t*, 521*t*
β-Lactam antibiotics. *See also* Penicillins
  for febrile neutropenia prevention, 1591*t*
  hypersensitivity reactions to, 884–885, 884*t*
  for urinary tract infections, 1291, 1293–1294
Bethanechol, 871–872
Betrixaban, for venous thromboembolism treatment, 227–229, 228*f*, 228*t*–230*t*, 231
Bevacizumab, for cancer, 1399*t*, 1406
  colorectal, 1459*t*, 1461–1462, 1462*t*, 1464*t*, 1465–1466
  of lung, 1441*t*, 1442*t*
  ovarian, 1509*t*, 1510*t*, 1513*t*
Bexarotene, 1415*t*
Bezlotoxumab, for *Clostridioides difficile* infections, 1274
Bicalutamide, 1415*t*
  for cancer, 1399*t*, 1412, 1477, 1478*t*
Bicarbonate. *See* Sodium bicarbonate therapy
Bichloroacetic (BCA) acid, for genital warts, 1313, 1313*t*
Bictegravir, 1367*t*, 1368*t*, 1377*t*, 1378*t*
Biguanides, for diabetes mellitus, 713*t*, 716*t*, 717
Biktarvy, 1367*t*, 1377*t*
Bilateral learning, 69

Bile acid sequestrants. *See also specific drugs*
  for diabetes mellitus, 715*t*, 716*t*, 720
  for dyslipidemia, 273
  formulations, dosing and adverse effects of, 271*t*
Bimatoprost, for primary open-angle glaucoma, 1009*t*
Binimetinib, for cancer, 1400*t*, 1410, 1415*t*, 1492*t*, 1494, 1495*t*
Biochemical markers, in acute coronary syndromes, 160–161
Biogenic amine and receptor hypotheses, 634
Bioidentical hormones, for menopausal symptoms, 832
Biologic agents. *See also specific drugs*
  for allergic rhinitis, 1057
  for asthma, 299
  hypersensitivity reactions to, 886
  for inflammatory bowel disease, 362–363, 362*t*
  for psoriasis, 1095
  for rheumatoid arthritis, 958–959, 960*t*–962*t*
Biosimilars, 362, 958–959, 960*t*–961*t*
Bipolar disorder
  clinical presentation and diagnosis of, 652–653, 653*t*
  epidemiology and etiology of, 651
  outcome evaluation for, 661–662
  pathophysiology of, 651–652
  patient care process for, 662
  patient education about, 662
  patient encounters, 652, 654, 661
  treatment of
    antidepressants for, 655–656, 660
    antipsychotics for, 654–656, 658*t*, 660
    desired outcomes for, 653
    in elderly, 660–661
    general approach to, 653–654, 655*t*, 656*t*
    mood-stabilizing drugs for, 654–661, 656*t*, 658*t*
    nonpharmacologic, 654–655
    in pediatric patients, 660
    in pregnancy and postpartum, 661
Bisacodyl
  for constipation, 385*t*
  for opioid side effects, 579*t*
Bismuth subcitrate potassium, for *Helicobacter pylori*-associated ulcers, 351*t*
Bismuth subsalicylate (BSS)
  for diarrhea, 76, 391*t*, 392
  for *Helicobacter pylori*-associated ulcers, 351*t*
Bisoprolol
  adverse effects of, 195*t*
  for heart failure, 116*t*, 121
  for hypertension, 94*t*
  for ischemic heart disease, 149*t*
Bisphosphonates
  for breast cancer, 1431
  for multiple myeloma, 1557
  for osteoporosis, 943–945, 944*t*
Bite wound infections, 1225–1226, 1226*t*
Bivalirudin
  for acute coronary syndromes, 169*t*, 177
  adverse effects of, 181*t*
  for venous thromboembolism treatment, 231, 231*f*, 232*t*
Blastomycosis
  clinical presentation and diagnosis of, 1347
  epidemiology and etiology of, 1345–1346, 1346*f*
  outcome evaluation for, 1349–1351, 1350*t*
  pathophysiology of, 1347, 1347*f*
  prophylaxis of, 1351
  treatment of, 1348–1349, 1348*t*
Bleeding, gastrointestinal, treatment of, in peptic ulcer disease, 354
Bleomycin
  for cancer, 1399*t*, 1404–1405
  dose modification with hepatic or renal dysfunction, 1414*t*
  for Hodgkin lymphoma, 1521*t*
Blinatumomab, for cancer, 1399*t*, 1406
Blood glucose
  elevated. *See also* Hyperglycemia
    chronic kidney disease and, 455
  low, treatment of, 723–724
  parenteral nutrition complications with, 1623–1624
Blood pressure. *See also* Hypertension; Hypotension
  in chronic kidney disease, 455, 457
  management of, for stroke prevention, 252
  measurement, 90, 90*t*
Blood products
  for acute complications of sickle cell disease, 1144
  for anemia, 1106
  chronic, for sickle cell disease, 1142–1143
  for circulatory shock, 287
  hemolytic transfusion reactions and, in sickle cell disease, 1143
  for immune thrombocytopenia, 1128
  for recessively inherited coagulation disorders, 1126, 1126*t*
  for sepsis and septic shock, 1328
Bloodstream candidiasis, 1353, 1354*t*
BMD. *See* Bone mineral density
BMI. *See* Body mass index
Body fluid compartments, 479–480, 480*t*

Circulatory shock
  clinical presentation and diagnosis of, 282
  epidemiology and etiology of, 279, 280*f*
  outcome evaluation for, 290
  pathophysiology of, 281–282, 281*f*, 281*t*
  patient care process for, 289
  patient encounters, 283, 288, 289
  treatment of
    blood products for, 287
    desired outcomes for, 282–283
    fluid therapy for, 283, 286–287, 286*t*, 287*f*
    general approach to, 283, 284*f*, 285*f*, 286–287
    hemostatic agents for, 289
    pharmacologic, 287–289, 288*t*
    supportive care measures for, 289–290
Cirrhosis
  clinical presentation and diagnosis of, 405–407
  epidemiology and etiology of, 401–402
  hepatitis and, 423
  outcome evaluation for, 411
  pathophysiology of
    ascites and, 402–403, 404*f*
    bleeding diathesis and synthetic failure and, 406
    hepatic encephalopathy and, 404–405
    hepatorenal syndrome and, 403–404
    portal hypertension and, 402, 403*f*, 404*f*
    spontaneous bacterial peritonitis and, 404
    varices and, 404
  patient care process for, 411
  patient encounters, 407, 408, 410
  portal hypertension and, 402, 403*f*, 404*f*
  treatment of
    for ascites, 408–409
    for coagulation abnormalities, 410–411
    desired outcomes for, 407
    for encephalopathy, 410
    for hepatorenal syndrome, 410
    nonpharmacologic, 407–408
    for portal hypertension, 408
    for spontaneous bacterial peritonitis, 409–410
    for varices, 409, 409*f*
Cisplatin, for cancer, 1399*t*, 1404
  of lung, 1441*t*, 1443*t*
  malignant melanoma, 1495*t*
  non-Hodgkin lymphoma, 1525*t*
  ovarian, 1509*t*, 1510*t*
Citalopram
  for generalized anxiety disorder, 670*t*
  for major depressive disorder, 638*t*, 639*t*, 640*t*
  for menopausal symptoms, 833*t*
  for panic disorder, 672*t*
  for social anxiety disorder, 672*t*
CIU. *See* Chronic idiopathic urticaria
CIWA-Ar. *See* Clinical Institute Withdrawal Assessment–Alcohol, Revised
CKD. *See* Chronic kidney disease
Cladribine, for multiple sclerosis, 518*t*, 521*t*, 522
Clarithromycin
  for *Helicobacter pylori*-associated ulcers, 351*t*
  for infective endocarditis prophylaxis, 1251*t*
  for pneumonia, 1190*t*, 1193*t*
Clascoterone, for acne, 1067, 1069, 1069*t*
Clevidipine, for hypertensive crisis, 102*t*
Clidinium bromide/chlordiazepoxide hydrochloride, for irritable bowel syndrome, 397*t*
Clindamycin
  for acute bacterial rhinosinusitis, 1206*f*, 1207*t*
  adverse drug reactions of, 1159*t*
  for bacterial vaginosis, in pregnancy, 795*t*
  for cellulitis, 1221*t*
  for cystic fibrosis, 330*t*
  for diabetic foot infections, 1225*t*
  for group B *Streptococcus* infection, in pregnancy, 794*t*
  for impetigo, 1218
  for infective endocarditis prophylaxis, 1251*t*
  for mastitis, 795*t*
  for osteomyelitis, 1232*t*
  for pelvic inflammatory disease, 1317*t*
  for pharyngitis, 1209*t*
  topical, for acne, 1067, 1068*t*
Clinical Institute Withdrawal Assessment–Alcohol, Revised (CIWA-Ar), 598*t*, 601
Clinical Opiate Withdrawal Scale (COWS), 598*t*, 602
CLL. *See* Chronic lymphocytic leukemia
Clobazam, for epilepsy, 535*t*
Clobetasol, topical, for psoriasis, 1092*t*
Clomiphene, lactation and, 791*t*
Clomipramine
  for panic disorder, 672*t*
  for social anxiety disorder, 672*t*

Clonal expansion, T-cell, 893
Clonazepam
  for epilepsy, 535*t*
  for generalized anxiety disorder, 671*t*
  for parasomnias, 688
Clonidine
  for attention-deficit/hyperactivity disorder, 697*t*, 698
  for hypertension, 95*t*
  for menopausal symptoms, 832, 833*t*
Clopidogrel
  for acute coronary syndromes, 167*t*, 174, 175*t*–176*t*, 176, 179
    prevention of, 145–146
  adverse effects of, 181*t*
  for stroke prevention, 250, 251, 253*t*
Clorazepate, for generalized anxiety disorder, 671*t*
Clostridioides difficile infection (CDI), 1268*t*, 1272–1274
  antimicrobial therapy and, 1157, 1272
  with enteral nutrition, 1638
Clostridium botulinum, food poisoning due to, 1276*t*
Clostridium perfringens, food poisoning due to, 1276*t*
Clotrimazole
  for breast candidiasis, 795*t*–796*t*
  for oropharyngeal candidiasis, 1338
  for tinea infections, 1342*t*
  for vulvovaginal candidiasis, 1335*t*
Clotting cascade, 215, 217*f*
Clozapine
  metabolism and drug interactions of, 627*t*
  for schizophrenia, 616*t*, 623*t*, 625–626, 625*t*
  side effects of, 617*t*
Clubbing, finger tip, in infective endocarditis, 1240, 1241*f*
Cluster headache
  clinical presentation and diagnosis of, 587
  epidemiology of, 585
  etiology and pathophysiology of, 586
  pharmacologic therapy for, 590
  prophylaxis of, 591–592
CML. *See* Chronic myelogenous leukemia

Excessive daytime sedation, 687
Exemestane, for cancer, 1399*t*, 1412, 1415*t*, 1427, 1428*t*
Exenatide, for diabetes mellitus, 718, 719*t*
Exercise, for osteoporosis, 941
Exfoliative dermatitis, drug-induced, 886
Exogenous infections, 1152, 1152*f*
Expectorants
  for common cold, 1212*t*
  for cough, 1040*t*
Exserohilum rostratum, 1345
Extended Spectrum Beta-Lactamase producing Gram-Negative organisms (ESBLs), risk factors for, 1161*t*
External beam radiation therapy (EBRT), for prostate cancer, 1476
Extrapulmonary tuberculosis, 1256, 1260
Extrapyramidal side effects, of antipsychotics, 615, 619
Extravasation, cancer chemotherapy and, 1413
Eyes. *See* Conjunctivitis; Dry eye; Keratitis; Ocular *entries*; Retinopathy
Ezetimibe
  for acute coronary syndrome prevention, 144
  for dyslipidemia, 273
  formulations, dosing and adverse effects of, 271*t*–272*t*

F
Factor IX inhibitors, in treatment of patients with hemophilia, 1120, 1122, 1122*f*
Factor IX replacement, for hemophilia B, 1120
Factor VIII inhibitors, in treatment of patients with hemophilia, 1120, 1122, 1122*f*
Factor VIII replacement
  for hemophilia A, 1120, 1121*t*, 1122*t*
  for von Willebrand disease, 1124, 1125*t*
Factor Xa inhibitors, for venous thromboembolism
  prevention, 222
  treatment, 223*t*, 227–231, 228*f*, 228*t*–230*t*
Fagerström Test for Nicotine Dependence, 598*t*
Falls
  medication-related, in elderly, 8
  prevention of, in osteoporosis, 941
Famciclovir
  for cold sores, 1035*t*
  for genital herpes, 1315*t*
Famotidine
  for anaphylactic reactions, 884*t*
  for gastroesophageal reflux disease, 339*t*, 340*t*
  for peptic ulcer disease, 353*t*
Fam-trastuzumab deruxtecan, for cancer, 1400*t*, 1407
Fatigue, in multiple sclerosis, treatment of, 524, 524*t*
Fats, in enteral nutrition formulas, 1636
Febrile neutropenia (FN)
  clinical presentation and diagnosis of, 1588
  epidemiology and etiology of, 1586, 1586*t*
  outcome evaluation for, 1593
  pathophysiology of, 1586–1587, 1587*t*, 1588*t*
  patient encounters, 1587
  prevention of, 1587–1589, 1589*t*
  treatment of, 1589, 1590*f*, 1591*t*–1592*t*, 1592–1593
Febuxostat
  for gout prevention, 984*t*, 985
  for tumor lysis syndrome, 1604
Fecal microbiota transplantation (FMT), for diarrhea, 393
Fedratinib, 1415*t*
Feeding tubes. *See* Enteral nutrition
Felbamate, for epilepsy, 536*t*
Felodipine
  for hypertension, 95*t*
  for ischemic heart disease, 149, 150*t*
Fenfluramine, 533*t*
  for epilepsy, 536*t*
Fenofibrate, formulations, dosing and adverse effects of, 272*t*
Fenoldopam, for hypertensive crisis, 102*t*
Fenoprofen, for gout, 983*t*
Fentanyl, equianalgesic dose of, 577*t*
Ferric carboxymaltose, for anemia of chronic kidney disease, 461*t*

Ferric citrate, for hyperphosphatemia, in chronic kidney disease, 465*t*, 466
Ferric derisomaltose, for anemia of chronic kidney disease, 461*t*
Ferric gluconate, for anemia of chronic kidney disease, 461*t*
Fertility
  antirheumatic drugs and, 963–965
  rate of, 61, 63*f*
Fertility awareness-based contraceptive methods, 814
Ferumoxytol, for anemia of chronic kidney disease, 461*t*, 462
Fesoterodine, for urge urinary incontinence, 868, 869*t*, 870*t*
Festination, in Parkinson disease, 559
Fetal development
  antirheumatic drugs and, 963–965
  phases of, 785–787, 786*t*, 787*f*
Fetal hemoglobin inducers, for sickle cell disease, 1140
Fetal lung maturation, 792, 793*t*
Fever
  returned traveler and, 77–78, 77*t*, 78*f*
  in sickle cell disease, 1144
Fexofenadine, for allergic rhinitis, 1054–1055, 1055*t*
FGFR inhibitors. *See* Fibroblast growth factor receptor inhibitors
Fiber, in enteral nutrition formulas, 1635
Fibrates. *See also specific drugs*
  for dyslipidemia, 274
  formulations, dosing and adverse effects of, 272*t*
Fibrinolytic effects, of anti-inflammatory mediators, 1322
Fibrinolytic therapy
  for acute coronary syndromes, 170*t*
  adverse effects of, 181*t*
  indications and contraindications for, 161, 162*t*
  for stroke prevention, 248–250, 249*t*
  for ST-segment elevation myocardial infarction, 165–166, 167*t*–172*t*
Fibroadenomas, breast, 807
Fibroblast growth factor receptor (FGFR) inhibitors, for cancer, 1400*t*, 1410
Fidaxomicin, for *Clostridioides difficile* infections, 1272–1274
Filgrastim
  for febrile neutropenia prevention, 1588–1589, 1589*t*
  for hematopoietic stem cell collection, 1564
Finasteride, for benign prostatic hyperplasia, 855–856, 855*t*
Fingernails, tinea infections of, 1340–1344, 1340*t*, 1342*t*
Fingolimod, for multiple sclerosis, 519*t*, 520, 522
First-generation antipsychotics. *See* Antipsychotics
Flecainide
  adverse effects of, 195*t*
  for atrial fibrillation, 196*t*, 198*t*
Flexural psoriasis, 1087, 1089
Floppy iris, 854
Flow cytometry, 1530–1531
Fluconazole
  for breast candidiasis, 795*t*
  for CNS infections, 1175*t*
  for cryptococcosis, 1354*t*, 1356
  for endemic fungal infections, 1348–1351, 1348*t*
  for febrile neutropenia prevention, 1591*t*
  in hematopoietic stem cell transplantation recipients, 1575
  for invasive candidiasis, 1353, 1354*t*, 1355
  for oropharyngeal and esophageal candidiasis, 1338–1339
  teratogenicity of, 788*t*
  for tinea infections, 1342*t*
  for vulvovaginal candidiasis, 799, 1335–1336, 1335*t*
Flucytosine
  for CNS infections, 1175*t*
  for cryptococcosis, 1354*t*, 1356
  for endemic fungal infections, 1350*t*
Fludarabine, for cancer, 1399*t*, 1401, 1551, 1552*t*
Fludrocortisone
  for adrenal insufficiency, 754–755
  pharmacologic characteristics of, 754*t*
Fluid and electrolyte homeostasis
  elderly patients, 6–7
  with enteral nutrition, 1640
  in pediatric patients, 16, 19*t*
Fluid therapy
  for acute kidney injury, 442, 442*t*
  for acute pancreatitis, 415–416
  for circulatory shock, 283, 286–287, 286*t*, 287*f*
  colloids for, 482
  crystalloids for, 481–482, 481*t*
  for diarrhea, 391
  for gastrointestinal infections, 1267, 1269*t*
  for intra-abdominal infections, 1283
  for sepsis, 1324
  strategies for, 482–483
Fluids
  in parenteral nutrition admixtures, 1615
  patient care process for, 491
  requirements for, 480, 480*t*
Flumazenil, for hepatic encephalopathy, 410
Flunisolide, for allergic rhinitis, 1053, 1053*t*
Fluoroquinolone-resistant organisms, risk factors for, 1161*t*
Fluoroquinolones
  administration through feeding tubes, 1642
  adverse drug reactions of, 1159*t*
  for bacterial keratitis, 1024*t*
  for prostatitis, 1295
  for traveler's diarrhea, 76, 76*t*
  for urinary tract infections, 1291, 1292*t*, 1293–1294
Fluorouracil
  for cancer, 1397
    colorectal, 1459*t*, 1460–1462, 1462*t*, 1463, 1464*t*
    keratinocyte carcinoma, 1497–1498, 1498*t*
  for genital warts, 1313
  toxicity of, 1426*t*
Fluoxetine
  for generalized anxiety disorder, 670*t*
  for major depressive disorder, 638*t*, 639*t*, 640*t*
  for multiple sclerosis, 524*t*
  for panic disorder, 672*t*
  for posttraumatic stress disorder, 676, 677*t*
  pregnancy changes to pharmacokinetics of, 790*t*
  for social anxiety disorder, 672*t*
Fluphenazine
  metabolism and drug interactions of, 627*t*
  for schizophrenia, 619*t*, 620*t*, 621*t*
Flurazepam, for insomnia, 686*t*
Flutamide, 1415*t*
  for cancer, 1399*t*, 1412, 1477, 1478*t*
Fluticasone
  for chronic obstructive pulmonary disease, 316*t*
  for nonallergic rhinitis, 1030*t*
Fluticasone furoate
  for allergic rhinitis, 1053*t*
  for asthma, 297*t*, 298*t*
Fluticasone furoate/vilanterol, for chronic obstructive pulmonary disease, 317*t*
Fluticasone propionate
  for allergic rhinitis, 1053, 1053*t*
  for asthma, 297*t*, 298*t*
Fluticasone propionate/salmeterol
  for asthma, 297*t*, 298*t*
  for chronic obstructive pulmonary disease, 317*t*
Fluticasone/umeclidinium/vilanterol, for asthma, 297*t*, 300*t*
Fluvastatin
  for dyslipidemia, 266*t*
  formulations, dosing and adverse effects of, 268–269, 271*t*
Fluvoxamine
  for generalized anxiety disorder, 670*t*
  for major depressive disorder, 638*t*, 639*t*, 640*t*
  for panic disorder, 672*t*
  for social anxiety disorder, 672*t*
FMT. *See* Fecal microbiota transplantation

  outcome evaluation for, 986–988
  pathophysiology of, 979–980
  patient care process for, 987
  patient encounters, 981, 986
  prevention of, 984–986, 984*t*
  treatment of, 981–983, 982*f*, 983*t*

gp120 attachment inhibitor, 1366, 1379
Graduated compression stockings (GCS), for venous thromboembolism prevention, 219
Graft failure, with hematopoietic stem cell transplantation, 1570
Graft-versus-host disease (GVHD)
  acute
    adaptive dosing of calcineurin inhibitors and, 1568
    clinical presentation, diagnosis, and staging of, 1570, 1571*t*
    immune suppression for, 1568
    treatment of, 1571–1572, 1571*t*
  chronic, 1573–1574
  hematopoietic stem cell transplantation and, 1561
  pathophysiology of, 1562–1564, 1563*f*
  patient encounters, 1576
Graft-versus-tumor (GVT) effect, hematopoietic stem cell transplantation and, 1561, 1565–1566, 1576
Gram-negative bacteria
  bacillary meningitis due to, 1179
  infective endocarditis due to, 1238*t*, 1243, 1248
Granisetron
  for chemotherapy-induced nausea and vomiting, 1584*t*
  for nausea and vomiting, 377*t*
Granuloma
  fungal, 1347
  tuberculous, 1256
Graves' disease, 740–741, 741*f*
  in pregnancy, 743–744
  treatment of, 741–742
Greenfield filters, for venous thromboembolism prevention, 221
Griseofulvin, for tinea infections, 1342*t*
Group A *Streptococcus*
  intra-abdominal infections due to, 1281, 1282*t*
  skin and skin structure infections due to, 1217–1220, 1221*t*, 1222
  upper respiratory tract infections due to, 1207–1208
Group B *Streptococcus* (GBS)
  CNS infections due to, 1167, 1169*t*, 1173*t*, 1179
  in pregnancy, 792, 794*t*, 797
Growth charts, for pediatric patients, 15, 17*f*, 18*f*
Growth hormone (GH), 765–766, 766*t*
  deficiency of
    clinical presentation and diagnosis of, 774
    epidemiology and etiology of, 773
    outcome evaluation for, 776–777
    pathophysiology of, 773–775
    patient care process for, 776, 777
    pharmacologic treatment of, 775–776, 775*t*
  excess of
    clinical presentation and diagnosis of, 768
    epidemiology and etiology of, 766
    outcome evaluation for, 772–773
    pathophysiology of, 767, 767*f*
    patient care process for, 773
    patient encounters, 769, 772
    treatment of, 767–768, 769*f*, 770*t*, 771–772
Growth hormone receptor antagonists, for growth hormone excess, 770*t*, 771
Growth hormone-inhibiting hormone (GHIH), for growth hormone excess, 768, 771
GSM. *See* Genitourinary symptoms of menopause
Guaifenesin
  for common cold, 1212*t*
  for cough, 1040*t*
Guanfacine
  for attention-deficit/hyperactivity disorder, 697*t*, 698
  for hypertension, 95*t*
Guanylate cyclase-C (GC-C) agonists, 386–387, 396, 397*t*
Gummatous syphilis, 1309*t*
Guselkumab, for psoriasis, 1100*t*
Gut barrier function, 1631
Gut-associated lymphoid tissue (GALT), 1631
Guttate psoriasis, 1087, 1089
GVHD. *See* Graft-versus-host disease

Irinotecan, for cancer, 1400*t*, 1403
  colorectal, 1459*t*, 1461, 1462*t*, 1463, 1464*t*, 1465
  of lung, 1441*t*
IRIS. *See* Immune reconstitution inflammatory syndrome
Iron
  in parenteral nutrition admixtures, 1617
  in pregnancy, 791–792, 793*t*
Iron dextran, for anemia of chronic kidney disease, 461–462, 461*t*
Iron homeostasis, dysregulation of, anemia and, 1104
Iron sucrose, for anemia of chronic kidney disease, 461*t*
Iron supplementation
  for anemia of chronic kidney disease, 459–462, 460*f*, 461*t*
  for iron-deficiency anemia, 1108–1110, 1109*t*, 1110*t*
  for restless legs syndrome, 688
Iron-deficiency anemia (IDA)
  pathophysiology of, 1103–1104, 1106*f*
  in pregnancy, 791–792, 793*t*
  treatment of, 1106, 1108–1110, 1109*t*, 1110*t*
Irritable bowel syndrome (IBS)
  clinical presentation and diagnosis of, 393–394
  diarrhea of, 389
  epidemiology and etiology of, 393
  outcome evaluation for, 398
  pathophysiology of, 393
  patient care process for, 398
  patient encounter, 395
  treatment of
    desired outcomes for, 394–395
    nonpharmacologic, 395
    pharmacologic, 395–398, 397*t*
Irritant contact dermatitis (ICD), 1075, 1076*f*, 1076*t*, 1077
Isatuximab, for cancer, 1399*t*, 1407
Isavuconazole
  for aspergillosis, 1354*t*, 1358–1359
  for endemic fungal infections, 1348–1349, 1350*t*
  for febrile neutropenia prevention, 1591*t*, 1593
  for invasive candidiasis, 1353
Isavuconazonium, for aspergillosis, 1354*t*, 1359
Ischemia, in osteomyelitis, 1230
Ischemic heart disease (IHD)
  angina and, 135, 137*f*, 138*t*
  clinical presentation and diagnosis of, 138, 139*t*, 140–141, 140*t*
  epidemiology and etiology of, 135–136
  imbalance in, 135, 136*f*
  pathophysiology of, 136, 138, 139*f*
  patient care process for, 153
  patient encounters, 143, 151
  risk factors for, 136, 138*t*
  treatment of
    acute coronary syndromes and death prevention, 144–147, 146*t*, 147*t*
    desired outcomes for, 141, 141*f*
    duration of, 153
    general approach to, 141–143, 142*f*
    interventional approaches to revascularization for, 144
    lifestyle modifications, 143–144
    nitroglycerin to relieve acute symptoms, 147–148
    with no benefit or potentially harmful effects, 151–152
    outcome evaluation for, 152
    recurrent ischemic symptoms prevention, 148–151, 148*t*–151*t*
    in special populations, 152
Ischemic stroke, 243
  pathophysiology of, 244
  primary prevention of
    aspirin for, 244
    risk factors and, 245–246
  risk factors for, 244, 244*t*
  in sickle cell disease, 1144
  treatment of
    antiplatelet agents for, 250
    desired outcomes for, 246
    fibrinolytic therapy for, 248–250, 249*t*
    general approach for, 246, 247*f*
    heparin for, 250
    low-molecular-weight heparin and heparinoids for, 250
    nonpharmacologic, 250–251
    secondary prevention and, 251–252
    supportive measures for, 246–247, 248*t*
    thrombin inhibitors for, 250
Isocarboxazid, for major depressive disorder, 640*t*
Isocitrate dehydrogenase (IDH) inhibitors, for cancer, 1400*t*, 1410
Isoniazid
  adverse drug reactions of, 1157*t*
  for tuberculosis, 1260–1261, 1260*t*, 1261*t*, 1262*t*, 1263–1264
Isoproterenol, for torsades de pointes, 208–209
Isosorbide, for primary open-angle glaucoma, 1013
Isosorbide dinitrate, for ischemic heart disease, 150*t*
Isosorbide dinitrate-hydralazine
  for heart failure, 117*t*, 120–121
  for hypertension, 96*t*
Isotretinoin
  for acne, 1069, 1071–1072, 1071*t*
  teratogenicity of, 788*t*
Isradipine, for hypertension, 95*t*
Istradefylline, for Parkinson disease, 563*t*, 566
ITP. *See* Immune thrombocytopenia
Itraconazole
  for cryptococcosis, 1356
  for endemic fungal infections, 1348–1351, 1348*t*, 1350*t*
  in hematopoietic stem cell transplantation recipients, 1575
  for invasive candidiasis, 1353, 1355
  for oropharyngeal and esophageal candidiasis, 1338–1339
  for tinea infections, 1342, 1342*t*
  for vulvovaginal candidiasis, 1335–1336, 1335*t*
IUDs. *See* Intrauterine devices
Ivabradine
  adverse effects of, 118*t*
  for heart failure, 117*t*, 122–123
Ivacaftor, for cystic fibrosis, 329*t*, 333–334
IVC filters. *See* Inferior vena cava filters
IVIG. *See* Intravenous immunoglobulin
Ivosidenib, for cancer, 1400*t*, 1410, 1415*t*
Ixabepilone, for cancer, 1399*t*, 1402

Metabolic resuscitation, for sepsis and septic shock, 1328
Metabolic syndrome, 703, 703*t*
Metabolism, drug–drug interactions of, immunosuppressants, 903, 904*t*
Metastases, 1389, 1392
Metered-dose inhalers (MDIs), for asthma, 296
Metformin
  for diabetes mellitus, 713*t*
  for menstrual disorders, 820*t*, 824
Methadone
  dose conversions for, 580, 580*t*
  drug interactions of, 600*t*
  equianalgesic dose of, 577*t*
  for opioid use, 602, 605–606
Methazolamide, for primary open-angle glaucoma, 1009*t*, 1012
Methicillin-resistant *Staphylococcus aureus* (MRSA)
  CNS infections due to, 1174*t*
  in cystic fibrosis, 326, 330
  infective endocarditis due to, 1248–1249
  osteomyelitis due to, 1229, 1231, 1232*t*
  pneumonia due to, 1185, 1190*t*, 1191
  risk factors for, 1161*t*
  skin and skin structure infections due to, 1217–1220, 1221*t*, 1222–1223, 1225*t*
Methicillin-sensitive *Staphylococcus aureus* (MSSA)
  in cystic fibrosis, 330
  osteomyelitis due to, 1232*t*
Methimazole (MMI)
  for hyperthyroidism, 742, 744, 745, 795*t*
  teratogenicity of, 788*t*
Methotrexate, 1416*t*
  for cancer, 1399*t*, 1401, 1525*t*
  for inflammatory bowel disease, 362, 362*t*
    in special populations, 367*t*
  for psoriasis, 1091, 1096*t*
  for rheumatoid arthritis, 956, 958, 960*t*
  for systemic lupus erythematosus, 920–921, 925*t*, 929
  teratogenicity of, 788*t*
  toxicity of, 1426*t*
Methoxy PEG-epoetin beta, for anemia of chronic kidney disease, 462*t*
Methyl aminolevulinate (MAL), for keratinocyte carcinoma, 1497, 1498*t*
Methyl nicotinate, for musculoskeletal disorders, 996, 997*t*
Methyl salicylate, for musculoskeletal disorders, 996, 997*t*
Methylcellulose
  for constipation, 385*t*
  for irritable bowel syndrome, 397*t*
Methyldopa, for hypertension, 95*t*, 103, 795*t*
Methylergonovine, for postpartum hemorrhage, 794*t*
Methylnaltrexone, for opioid side effects, 579*t*
Methylnaltrexone bromide, for constipation, 386*t*, 387
Methylphenidate
  for attention-deficit/hyperactivity disorder, 695, 696*t*, 697*t*
  for multiple sclerosis, 524*t*
Methylprednisolone
  for acute graft-versus-host disease, 1571
  for asthma, 301–302, 301*t*
  for endemic fungal infections, 1349
  for gout, 983, 983*t*
  for inflammatory bowel disease, 361*t*, 364
  intraarticular, for osteoarthritis, 972*t*
  for multiple sclerosis, 516
  for nausea and vomiting, 377*t*
  for non-Hodgkin lymphoma, 1525*t*
  for organ transplantation, 901–902
  pharmacologic characteristics of, 754*t*
  for thrombotic thrombocytopenic purpura, 1132

Methylxanthines, for chronic obstructive pulmonary disease, 315, 316*t*
Methysergide, for migraine prophylaxis, 591
Metipranolol, for primary open-angle glaucoma, 1008*t*
Metoclopramide
  for gastroesophageal reflux disease, 342

Reproductive system, in cystic fibrosis, 327
Reserpine, for hypertension, 96*t*
Reslizumab, for asthma, 299, 300*t*
Respiratory acidosis
  diagnosis of, 495–496, 496*f*
  etiology and treatment of, 500, 500*t*
  pathophysiology of, 494, 494*t*, 495*t*
Respiratory alkalosis
  diagnosis of, 495–496, 496*f*
  etiology and treatment of, 500–501, 501*t*
  pathophysiology of, 494, 494*t*, 495*t*
Respiratory depression, as opioid side effect, 579*t*
Respiratory disease, aspirin-exacerbated, 885
Respiratory disturbance index (RDI), 682
Respiratory tract infections. *See* Acute bacterial rhinosinusitis; Common cold; Pneumonia; Upper respiratory tract infections
Response fluctuations, in Parkinson disease, 559, 567, 567*t*
Response inhibition, 693
Restless legs syndrome (RLS)
  clinical presentation and diagnosis of, 683
  epidemiology and etiology of, 682
  pathophysiology of, 682
  treatment of, 687–688, 688*t*
Resuscitation, for sepsis and septic shock, 1324
RET inhibitors, for cancer, 1400*t*, 1411
Retapamulin, for impetigo, 1218
Reteplase
  for acute coronary syndromes, 170*t*
  for venous thromboembolism treatment, 223*t*
Retinoids
  oral, for psoriasis, 1097*t*
  teratogenicity of, 788*t*
  topical
    for acne, 1067, 1068*t*, 1071*t*
    for psoriasis, 1092*t*, 1094*t*
Retinopathy, in diabetes mellitus, treatment of, 724–725
Revascularization, interventional approaches to. *See* Coronary artery bypass graft surgery; Percutaneous coronary intervention
Revefenacin, for chronic obstructive pulmonary disease, 316*t*
Reverse transcriptase, 1364
Reward pathway, substance use and, 595–596, 596*f*
Rhabdomyolysis, statins and, 269
Rheumatoid arthritis (RA)
  clinical presentation and diagnosis of, 953–954, 953*t*, 954*f*
  comorbidities associated with, 952–953
  epidemiology and etiology of, 951
  outcome evaluation for, 965
  pathophysiology of, 951–953, 952*t*
  patient care process for, 964
  patient encounters, 955, 963, 964
  treatment of
    biologic disease-modifying antirheumatic drugs for, 958–959, 960*t*–962*t*
    biosimilars for, 958–959, 960*t*–961*t*
    bridge therapy/symptomatic relief and, 955–956
    conventional synthetic disease-modifying antirheumatic drugs for, 956, 958, 960*t*
    desired outcomes for, 954
    fertility, pregnancy, and fetal development and, 963–965
    general approach to, 954–955, 956*f*, 957*f*
    nonpharmacologic, 955

selection of disease-modifying therapy for, 959, 960*t*–962*t*, 963
targeted synthetic disease-modifying antirheumatic drugs for, 959, 962*t*
vaccinations and, 963
Rhinitis
allergic. *See* Allergic rhinitis
nonallergic, 1029–1031, 1030*t*, 1032
Rhinosinusitis. *See* Acute bacterial rhinosinusitis
Rho kinase inhibitors, for primary open-angle glaucoma, 1009*t*, 1012
Ribavirin, for hepatitis C, 431*t*, 432
Ribociclib, for cancer, 1400*t*, 1409, 1416*t*
RICDs. *See* Recessively inherited coagulation disorders
RICE (rest, ice, compression, and elevation) therapy
for hemophilia, 1119
for musculoskeletal injuries, 993–994, 994*t*
Rifabutin
for *Helicobacter pylori*-associated ulcers, 351*t*
for tuberculosis, 1260, 1262*t*
Rifampin
adverse drug reactions of, 1157*t*
for chlamydia, 1305*t*
for CNS infections, 1174*t*
for infective endocarditis, 1247*t*, 1250*t*
for intra-abdominal infections, 1286*t*
for osteomyelitis, 1232*t*
for tuberculosis, 1260–1261, 1260*t*, 1261*t*, 1262*t*, 1263–1264
Rifapentine, for tuberculosis, 1260, 1260*t*, 1262*t*
Rifaximin
for *Clostridioides difficile* infections, 1274
for hepatic encephalopathy, 410
for irritable bowel syndrome, 397, 397*t*
for traveler's diarrhea, 76, 76*t*
Rilpivirine, 1367*t*, 1369*t*, 1371*t*, 1374*t*–1376*t*, 1378*t*, 1379, 1382*t*
Rimegepant, for migraine, 590
Ringer's lactate, 482
Ripretinib, 1416*t*
Risankizumab, for psoriasis, 1100*t*
Risedronate, for osteoporosis, 944*t*
Risperidone
metabolism and drug interactions of, 627*t*
for posttraumatic stress disorder, 678
for schizophrenia, 615, 616*t*, 617, 621*t*, 624*t*
side effects of, 617*t*
Ritonavir, 1366, 1369*t*, 1372*t*, 1376*t*, 1378*t*
Rituximab
for cancer, 1399*t*, 1407
chronic lymphocytic leukemia, 1551, 1552*t*
non-Hodgkin lymphoma, 1524*t*, 1525*t*
for immune thrombocytopenia, 1129
for multiple sclerosis, 519*t*, 522–523
for organ rejection, 902
for rheumatoid arthritis, 959, 961*t*
for systemic lupus erythematosus, 921, 927*t*, 930
Rivaroxaban
for atrial fibrillation, 199–200
for ischemic stroke treatment, 253*t*
for venous thromboembolism
prevention, 222, 223*t*
treatment, 227–230, 228*f*, 228*t*–230*t*
Rivastigmine, for Alzheimer disease, 506–507, 507*t*, 508*t*
Rizatriptan, for migraine, 589*t*, 591
RLS. *See* Restless legs syndrome
Roflumilast, for chronic obstructive pulmonary disease, 316*t*, 317
Rolapitant, for nausea and vomiting, 378*t*, 379, 1584*t*
Romidepsin, for cancer, 1399*t*, 1405
Romiplostim, for immune thrombocytopenia, 1129
Romosozumab, for osteoporosis, 944*t*, 946
Ropinirole
for Parkinson disease, 562*t*
for restless legs syndrome, 687, 688*t*
Rosiglitazone, for diabetes mellitus, 713*t*
Rosuvastatin
for acute coronary syndromes, 172*t*
for dyslipidemia, 266*t*
formulations, dosing and adverse effects of, 271*t*
Rotavirus infection, 1268*t*, 1274*t*, 1275
Roth spots, 1240, 1241*f*
Rotigotine
for Parkinson disease, 562*t*
for restless legs syndrome, 687, 688*t*
RRT. *See* Renal replacement therapy
RSE. *See* Refractory status epilepticus
RSI. *See* Rapid sequence intubation
Rubefacients, for musculoskeletal disorders, 996, 997*t*
Rucaparib, 1416*t*
for cancer, 1400*t*, 1411
ovarian, 1509*t*, 1510*t*
of prostate, 1480*t*, 1482*t*
Rufinamide, for epilepsy, 539*t*
Ruxolitinib, 1416*t*
for graft-versus-host disease, 1571

S

SABAs. *See* Short-acting beta blockers
Sacituzumab govitecan, for cancer, 1400*t*, 1408
Sacubitril/valsartan
adverse effects of, 118*t*
for heart failure, 116*t*, 120
SAD. *See* Social anxiety disorder
S-Adenosyl methionine (SAM-e), for major depressive disorder, 637
Safety
of cancer chemotherapy, 1413–1415, 1414*t*, 1415*t*–1416*t*
parenteral nutrition and, 1619
Safinamide, for Parkinson disease, 563*t*, 565
SAH. *See* Subarachnoid hemorrhage
Salicylates. *See also specific drugs*
for musculoskeletal disorders, 995
for pain, 576
topical, for psoriasis, 1093*t*
Saline
for allergic rhinitis, 1051–1052
for constipation, 386
half-normal, 481

Ventricular action potential, 186–187, 186f
Ventricular assist device (VAD), for heart failure, 130
Ventricular fibrillation (VF), 205–206, 206t, 207f
Ventricular hypertrophy, heart failure and, 109, 109t
Ventricular premature beats (VPBs), 203
Ventricular premature contractions (VPCs), 203
Ventricular premature depolarizations (VPDs), 203
Ventricular tachycardia (VT), 204–205, 204t, 205f
Ventriculitis, healthcare-associated, 1179
Verapamil
  adverse effects of, 181t, 195t
  for atrial fibrillation, 194t
  for cluster headache prophylaxis, 591
  for hypertension, 95t
  for ischemic heart disease, 148t, 149, 150t
  for paroxysmal supraventricular tachycardia, 202t
  for ventricular tachycardia, 204t

Vestibular nausea and vomiting, 33, 381
VF. *See* Ventricular fibrillation
Vigabatrin, for epilepsy, 540*t*
Vilanterol, for chronic obstructive pulmonary disease, 316*t*
Vilazodone
  for generalized anxiety disorder, 669
  for major depressive disorder, 636*t*, 637, 638*t*, 639*t*, 641*t*
Vinblastine, for cancer, 1399*t*, 1401–1402
  Hodgkin lymphoma, 1521*t*
  malignant melanoma, 1495*t*
Vinca alkaloids
  for cancer, 1399*t*, 1401–1402
  toxicity of, 1426*t*
Vincristine, for cancer, 1399*t*, 1401–1402
  Hodgkin lymphoma, 1521*t*
  non-Hodgkin lymphoma, 1524*t*, 1525*t*
Vinorelbine
  for cancer, 1399*t*, 1401–1402
    breast cancer, 1426*t*
    of lung, 1441*t*
    ovarian, 1513*t*
  toxicity of, 1426*t*
Viral conjunctivitis, 1021
Viral hepatitis. *See* Hepatitis, viral
Viral infections. *See also specific infections*
  CNS, 1170*t*, 1174*t*, 1179–1180
  gastroenteritis due to, 1267, 1268*t*, 1274–1275, 1274*t*
  neglected tropical diseases, 66*t*
  pneumonia due to, 1185–1186, 1191–1192, 1194–1195, 1195*t*
  sepsis and septic shock due to, 1321, 1322*t*
  upper respiratory tract infections due to, 1199–1200, 1210–1213
Visceral pain, 34, 35*f*
Viscoelastic testing, 287
Vision loss, 1018
Vismodegib, 1416*t*
  for cancer, 1400*t*, 1410
  for keratinocyte carcinoma, 1498
Vital signs, in pediatric patients, 15–16, 19*t*
Vitamin A, teratogenicity of, 788*t*
Vitamin B_{12} deficiency, anemia due to, 1104, 1105*f*, 1110
Vitamin C, for common cold, 1213
Vitamin D
  for hyperphosphatemia, in chronic kidney disease, 466–467, 466*t*
  for osteoporosis, 940–941, 943*t*
Vitamin D analogues, topical, for psoriasis, 1092*t*, 1094*t*
Vitamin E, for Alzheimer disease, 508
Vitamin K, for coagulopathy, in cirrhosis, 410
Vitamins
  depletion of, hemodialysis and, 472*t*, 473
  in enteral nutrition formulas, 1636
  in parenteral nutrition admixtures, 1616
  in pregnancy, 793*t*
  supplementation of, for cystic fibrosis, 332–333
VMS. *See* Vasomotor symptoms
VNS. *See* Vagus nerve stimulation
Voclosporin, for systemic lupus erythematosus, 930
Vomiting. *See* Nausea and vomiting
von Willebrand disease (vWD)
  clinical presentation and diagnosis of, 1125
  epidemiology and etiology of, 1123
  outcome evaluation for, 1125
  pathophysiology of, 1123, 1123*t*
  patient care process for, 1127
  patient encounters, 1123, 1126, 1127
  treatment of, 1123–1124, 1124*f*, 1125*t*
Voriconazole
  for aspergillosis, 1354*t*, 1358–1359
  for cryptococcosis, 1356
  for endemic fungal infections, 1348–1351, 1350*t*
  for febrile neutropenia prevention, 1592*t*, 1593
  for invasive candidiasis, 1353, 1354*t*, 1355
  for oropharyngeal and esophageal candidiasis, 1338–1339
Vorinostat, for cancer, 1399*t*, 1405, 1416*t*
Vortioxetine
  for generalized anxiety disorder, 669
  for major depressive disorder, 636*t*, 637, 638*t*, 639*t*, 641*t*
Voxelotor, for sickle cell disease, 1141–1142, 1142*t*
VPBs. *See* Ventricular premature beats
VPCs. *See* Ventricular premature contractions
VPDs. *See* Ventricular premature depolarizations
VRE. *See* Vancomycin-resistant enterococci
VT. *See* Ventricular tachycardia
VTE. *See* Venous thromboembolism
Vulvovaginal candidiasis (VVC)
  clinical presentation and diagnosis of, 1334
  epidemiology and etiology of, 1333
  outcome evaluation for, 1336–1337
  pathophysiology of, 1333
  patient care process for, 1336
  patient encounters, 1335
  during pregnancy and lactation, 799, 1336
  risk factors for, 1334*t*
  treatment of, 1333
    cultural awareness during, 1336
    for nonalbicans infections, 1336
    nonpharmacologic, 1334
    pharmacologic, 1334–1336, 1335*t*
    during pregnancy, 1336
    for recurrent vulvovaginal candidiasis, 1335–1336, 1335*t*
Vulvovaginitis, gonococcal, 1302*t*–1303*t*
VVC. *See* Vulvovaginal candidiasis
vWD. *See* von Willebrand disease
VZV. *See* Varicella zoster virus

W
Waist circumference (WC), 1646
Warfarin
  administration through feeding tubes, 1642
  for atrial fibrillation, 200
  drug interactions of, 236–237, 236*t*
  food interactions of, 236–237, 237*t*
  for ischemic stroke treatment, 253*t*
  during pregnancy and lactation, 798
  teratogenicity of, 789*t*
  for venous thromboembolism
    prevention, 221–222
    treatment, 232–237, 233*f*, 233*t*, 234*f*, 236*t*, 237*t*
Warts, genital, 1312–1314, 1313*t*
Water deficit, patient encounters, 485
WBC count and differential. *See* White blood cell count and differential
WC. *See* Waist circumference
Weight. *See* Overweight and obesity
Weight management, for diabetes mellitus, 708
Wenckebach block, 190
Wernicke syndrome, 598, 602
West syndrome, 531
White blood cell (WBC) count and differential, 1153, 1154*t*
Wild-type virus, HIV, 1378
Wilson disease, 813
  cirrhosis and, 402
Windup, pain, 572
Withdrawal, signs and symptoms of, 597, 599*t*
Withdrawal syndromes, treatment of, 601–603, 603*t*
Women
  epilepsy in, 541–543, 542*t*
  HIV/AIDS in, 1379–1380
Women who have sex with women (WSW), sexually transmitted infection risk and, 1299, 1306
Wound healing formulas, for enteral nutrition, 1638
WSW. *See* Women who have sex with women

X
Xerostomia, 1035–1037, 1037*t*

Y
Yellow fever vaccines, 75*t*

Z
Zafirlukast, for asthma, 299, 300*t*
Zaleplon, for insomnia, 686*t*
Zanamivir, for pneumonia, 1191
Zanubrutinib, for cancer, 1400*t*, 1409, 1416*t*
Zero-order pharmacokinetics, of anticonvulsants, 533
ZES. *See* Zollinger-Ellison syndrome
Zidovudine, 1370*t*, 1374*t*–1385*t*, 1382*t*–1383*t*
  anemia due to, treatment of, 1112–1113

Zileuton, for asthma, 299, 300*t*
Zinc, in parenteral nutrition admixtures, 1616–1617, 1616*t*
Ziprasidone
  metabolism and drug interactions of, 627*t*
  for schizophrenia, 616*t*, 617, 624*t*
  side effects of, 617*t*
Ziv-aflibercept, for colorectal cancer, 1462, 1464*t*, 1466
Zoledronic acid
  for hypercalcemia of malignancy, 1602*t*
  for multiple myeloma, 1557
  for osteoporosis, 943, 944*t*
Zollinger-Ellison syndrome (ZES), 348
Zolmitriptan, for migraine, 589*t*
Zolpidem, for insomnia, 686*t*
Zona fasciculata, 749, 750*f*
Zona glomerulosa, 749, 750*f*
Zona reticularis, 749, 750*f*
Zonisamide, for epilepsy, 540*t*
Zymogen, 413
